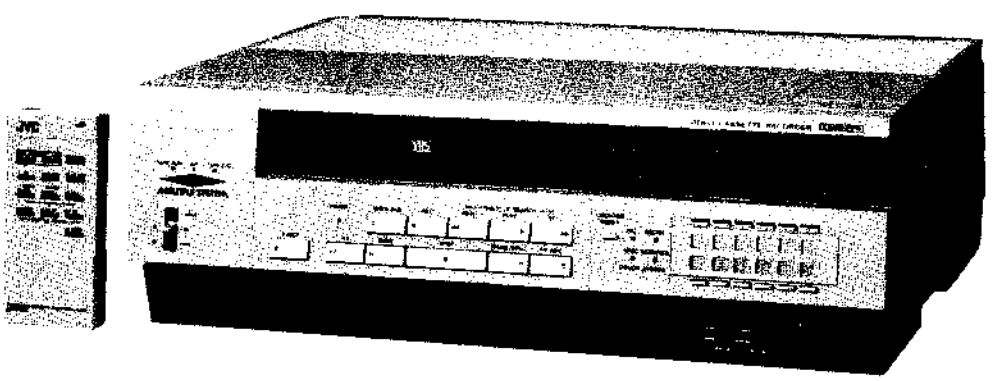
No. 8248

JVC Service Manual



MODEL **HR-7600MS**

VICTOR COMPANY OF JAPAN, LIMITED

Printed in Japan

Important Safety Precautions

Prior to shipment from the factory, JVC products are strictly inspected to conform with the recognized product safety and electrical codes of the countries in which they are to be sold. However, in order to maintain such compliance, it is equally important to implement the following precautions when a set is being serviced.

● Precautions during Servicing

1. Locations requiring special caution are denoted by labels and inscriptions on the cabinet, chassis and certain parts of the product. When performing service, be sure to read and comply with these and other cautionary notices appearing in the operation and service manuals.

2. Parts identified by the ⚠ symbol and shaded (▬) parts are critical for safety.
   Replace only with specified part numbers.
   Note: Parts in this category also include those specified to comply with X-ray emission standards for products using cathode ray tubes and those specified for compliance with various regulations regarding spurious radiation emission.

3. Use specified internal wiring. Note especially:
   1) Wires covered with PVC tubing
   2) Double insulated wires
   3) High voltage leads

4. Use specified insulating materials for hazardous live parts. Note especially:
   1) Insulation Tape
   2) PVC tubing
   3) Spacers
   4) Insulation sheets for transistors

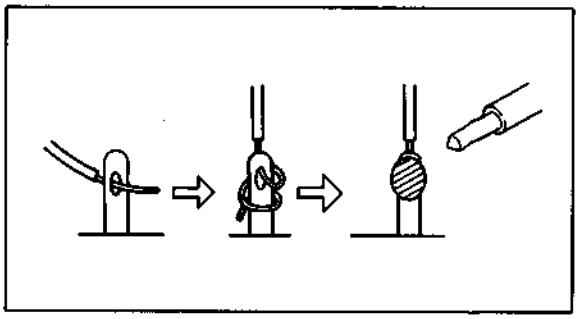


Fig. 1

5. When replacing AC primary side components (transformers, power cords, noise blocking capacitors, etc.) wrap ends of wires securely about the terminals before soldering.

6. Observe that wires do not contact heat producing parts (heatsinks, oxide metal film resistors, fusible resistors, etc.)

7. Check that replaced wires do not contact sharp edged or pointed parts.

8. When a power cord has been replaced, check that 10–15 kg of force in any direction will not loosen it.

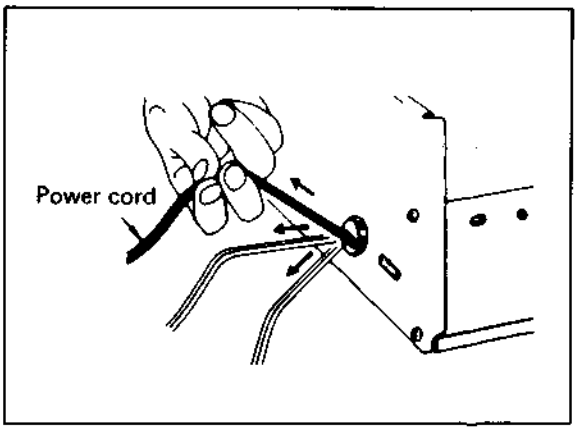

Fig. 2

9. Also check areas surrounding repaired locations.

10. Products using cathode ray tubes (CRTs)
    In regard to such products, the cathode ray tubes themselves, the high voltage circuits, and related circuits are specified for compliance with recognized codes pertaining to X-ray emission. Consequently, when servicing these products, replace the cathode ray tubes and other parts with only the parts specified. Under no circumstances attempt to modify these circuits. Unauthorized modification can increase the high voltage value and cause X-ray emission from the cathode ray tube.

11. Crimp type wire connector

In such cases as when replacing the power transformer in sets where the connections between the power cord and power transformer primary lead wires are performed using crimp type connectors, if replacing the connectors is unavoidable, in order to prevent safety hazards, perform carefully and precisely according to the following steps.

1. Connector part number : E03830-001
2. Required tool : Connector crimping tool of the proper type which will not damage insulated parts.
3. Replacement procedure
   1) Remove the old connector by cutting the wires at a point close to the connector.
      Important : Do not reuse a connector (discard it).
   2) Strip about 15 mm of the insulation from the ends of the wires. If the wires are stranded, twist the strands to avoid frayed conductors.
   3) Align the lengths of the wires to be connected. Insert the wires fully into the connector.
   4) As shown in Fig. 6, use the crimping tool to crimp the metal sleeve at the center position. Be sure to crimp fully to the complete closure of the tool.
   5) Check the four points noted in Fig. 7.

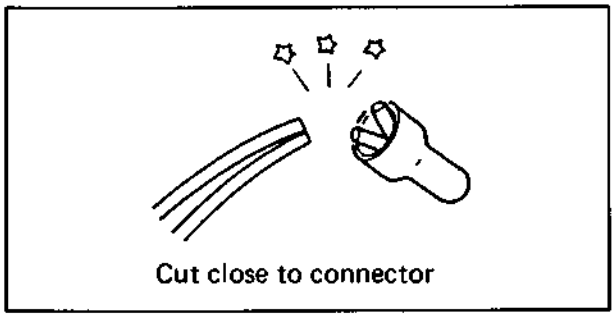

Fig. 3

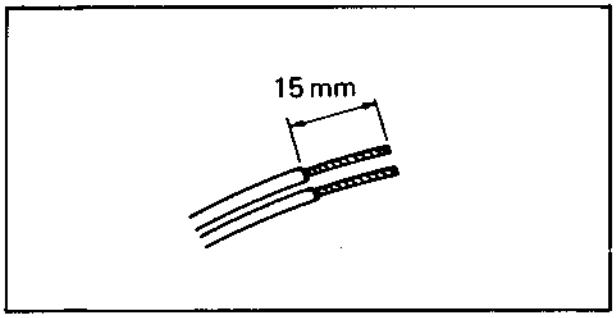

Fig. 4

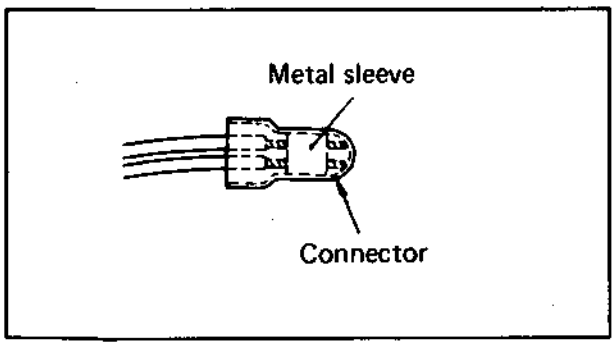

Fig. 5

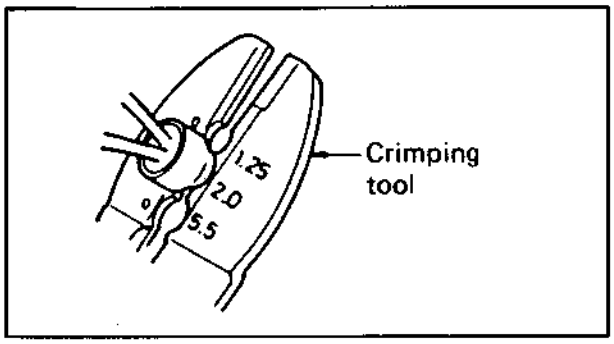

Fig. 6

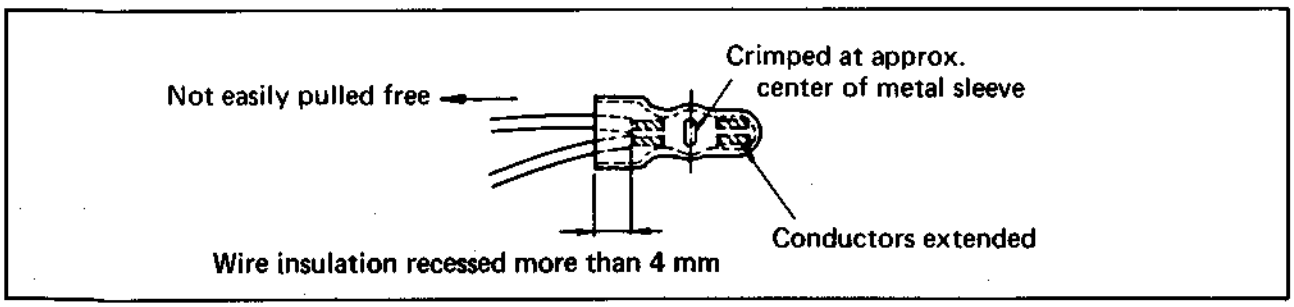

Fig. 7

● Safety Check after Servicing

Examine the area surrounding the repaired location for damage or deterioration. Observe that screws, parts and wires have been returned to original positions. Afterwards, perform the following tests and confirm the specified values in order to verify compliance with safety standards.

1. **Insulation resistance test**
   Confirm the specified insulation resistance or greater between power cord plug prongs and externally exposed parts of the set (RF terminals, antenna terminals, video and audio input and output terminals, microphone jacks, earphone jacks, etc.). See table below.

2. **Dielectric strength test**
   Confirm specified dielectric strength or greater between power cord plug prongs and exposed accessible parts of the set (RF terminals, antenna terminals, video and audio input and output terminals, microphone jacks, earphone jacks, etc.) See table below.

3. **Clearance distance**
   When replacing primary circuit components, confirm specified clearance distance (d),(d') between soldered terminals, and between terminals and surrounding metallic parts. See table below.

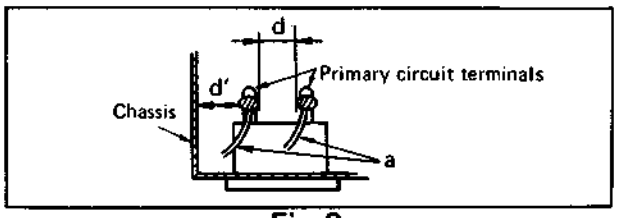

Fig. 8

Table 1: Ratings for selected areas

AC Line Voltage	Region	Insulation Resistance	Dielectric Strength	Clearance Distance(d),(d')
100 V	Japan	≧ 1 MΩ/500 V DC	1 kV 1 minute	≧ 3 mm
110 to 130 V	USA & Canada	— — —	900 V 1 minute	≧ 3.2 mm
* 110 to 130 V 200 to 240 V	Europe Australia	≧ 10 MΩ/500 V DC	4 kV 1 minute	≧ 6 mm (d) ≧ 8 mm (d') (a: Power cord)

* Class II model only.
Note. This table is unofficial and for reference only. Be sure to confirm the precise values for your particular country and locality.

4. **Leakage current test**
   Confirm specified or lower leakage current between B(earth ground, power cord plug prongs) and externally exposed accessible parts (RF terminals, antenna terminals, video and audio input and output terminals, microphone jacks, earphone jacks, etc.).

   Measuring Method: (Power ON)
   Insert load Z between B(earth ground,power cord plug prongs) and exposed accessible parts. Use an AC voltmeter to measure across both terminals of load Z. See figure and following table.

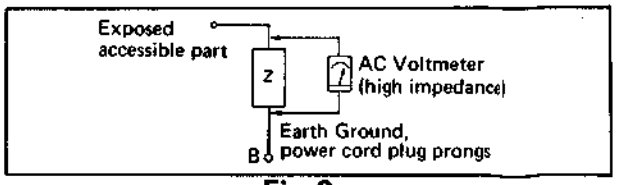

Fig. 9

Table 2: Leakage current ratings for selected areas

AC Line Voltage	Region	Load Z	Leakage Current (i)	Earth Ground (B) to:
100 V	Japan	1 kΩ	i ≦ 1m A rms	Exposed accessible parts
110 to 130 V	USA & Canada	0.15 μF, 1.5 kΩ	i ≦ 0.5m A rms	Exposed accessible parts
110 to 130 V 200 to 240 V	Europe Australia	2 kΩ	i ≦ 0.7 m A peak i ≦ 2 m A dc	Antenna earth terminals
		50 kΩ	i ≦ 0.7 m A peak i ≦ 2 m A dc	Other terminals

Note. This table is unofficial and for reference only. Be sure to confirm the precise values for your particular country and locality.

TABLE OF CONTENTS

HR-7600MS

INSTRUCTIONS

For reference, the text of the instruction booklet of this model is reproduced in the following pages.
Numbering of the pages also corresponds with that of the booklet.

Thank you for purchasing the JVC HR-7600MS Video Cassette Recorder. This unit conforms to the VHS video format developed for full home entertainment by JVC to provide high-quality recording and playback capability.
Besides the full complement of the most advanced features currently available, the HR-7600MS incorporates the circuitry required to record or play back the PAL, SECAM, or NTSC signals from any television broadcasting system in the world.
To obtain the best results and avoid malfunctions, please read this instruction booklet carefully and thoroughly before using your HR-7600MS.

CONTENTS

VHS
PAL SECAM NTSC
Only cassettes marked VHS can be used with this video cassette recorder.

WARNING:
TO PREVENT FIRE OR SHOCK HAZARD, DO NOT EXPOSE THIS UNIT TO RAIN OR MOISTURE.

CAUTION
Dangerous voltage inside. Refer internal servicing to qualified service personnel. To prevent electric shock or fire hazard, remove the power cord from the AC outlet prior to connecting or disconnecting any signal lead or aerial, prior to replacing the fuse, and prior to altering the voltage setting.

POWER SYSTEM
Connection to the mains supply
The operating voltage of this set is preset to 220 V ∿ at the factory.
Before connecting to mains, check that the voltage selector on the rear panel is set to the same voltage as your local mains supply.

Adapting to local power line
This set operates on either 110, 127, 220 or 240 V∿.
If the preset voltage is different from the power line voltage in your area, reset the voltage selector by inserting a screwdriver into the slot of the voltage selector and turning it until the correct voltage is displayed.

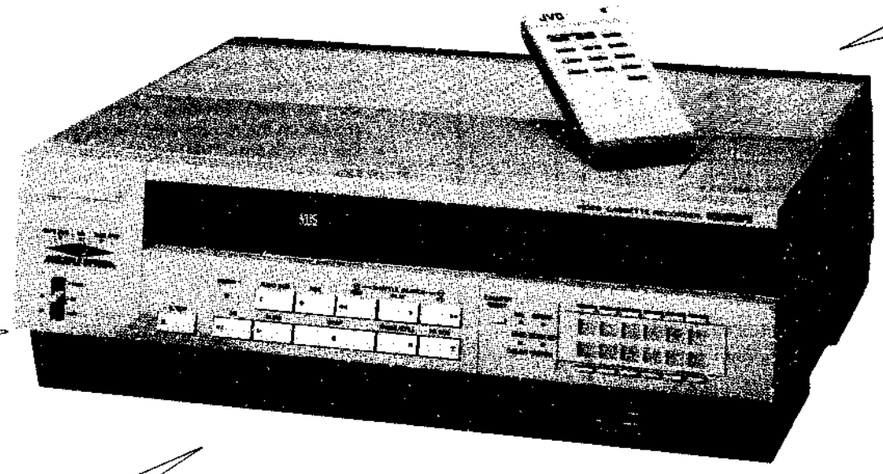
POWER SWITCH
The mains switch is located on the rear connector panel. Setting this switch to OFF removes all applied power from the set including the timer clock. Switching on or off the recorder section is performed with the secondary power switch on the front panel, which has three positions labelled "TIMER", "ON" and "OFF" (referred to as "sub-power switch").

IMPORTANT: It is permissible to record television programmes only in the event that third party copyrights and other rights are not violated.

NOTE: The rating plate and the safety caution are on the rear of the unit.

STRUCTURE OF THIS MANUAL

Your new HR-7600MS may be somewhat complicated to operate at first because of its highly advanced features. In order to help you master the operation of this unit, this booklet is divided into six parts. The ideas and contents of each part are described here. So first read this page and then you can start referring to any part depending on your situation.



PART I: GENERAL DESCRIPTION

This introduction to your new machine contains the handling precautions you must observe to be assured of safe operation, and a concise list of the HR-7600MS features and capabilities. Also included is a guide to selecting the appropriate circuitry for the broadcasting standard in your area, or the type of camera or tape you're using. For quick reference as you read the rest of this booklet, you will also find detailed drawings and a brief explanation of all controls and connectors.

PART II: PREPARATIONS

All that you have to do before actual use of this machine is described in Part II. First you have to connect this recorder to your TV set. Then you must pre-tune the built-in tuner to specific stations in your area. Also, since this unit has a built-in timer which also functions as an ordinary clock, you may wish to set it to the correct time, even though you are still not going to use its timer facility.

PART III: BASIC OPERATION

After the preparations, you are ready to record a TV programme while watching it or watching another one on a different channel, and then play back the recorded tape at any convenient time. This is the basic function of any deck-type video recorder. Although this machine is full of convenient features, the first step to familiarjze yourself with the working principle of this machine may be to master this procedure. With this in mind, this section is devoted to step-by-step explanation of this basic operation, beginning with "how to insert a cassette".

PART IV: ADVANCED USAGE

One big feature of the HR-7600MS is its timer recording facility. You can reserve recordings at any time within two weeks in advance for as much as eight TV programmes either individually, in series or in weekly repetitions.
Also, since the HR-7600MS is provided with a camera connector, JVC video cameras can be directly connected to make your own video movies easily. Its audio dubbing facility enables replacing the recorded sound with another sound track of your choice. If you are ready to fully utilize these facilities, refer to part IV.

PART V: ADDITIONAL FACILITIES

This is a cross-reference chapter which contains detailed description of several convenient facilities such as the cue and counter search functions for tape indexing, etc. These functions are briefly mentioned in other parts of this booklet when needed. However, refer to Part V whenever you wish to know the details of these functions, following the cross-reference indications.
Another subject of this section is the infrared remote control unit. Since most buttons on the remote control unit function in the same way as the corresponding buttons on the recorder, there may be no problem in using it. However, necessary precautions are mentioned in this section, so please refer to it before you start using the remote control unit.

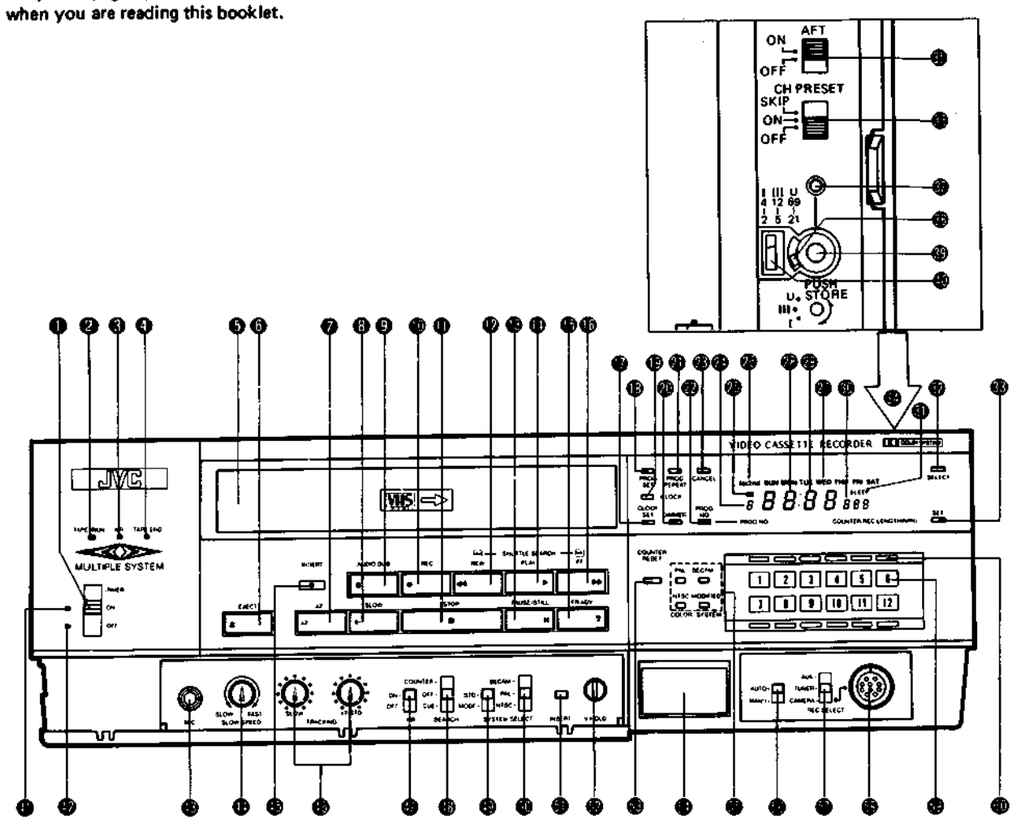
PART VI: SUPPLEMENTS

A simple troubleshooting guide, hints for maintenance and countermeasures for some problems with pictures on the TV screen are put together in this section. When you encounter some strange phenomena in using the HR-7600MS, reference to Part VI may help you.

PART I

GENERAL DESCRIPTION

Keep this page opened so that you can refer to it at any time when you are reading this booklet.



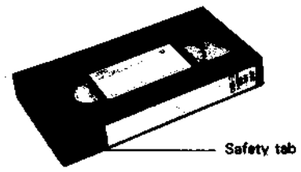
FEATURES

- PAL, SECAM and NTSC recording and playback circuitry.
- Motorized front-loading cassette system.
- Infrared remote control unit.
- Microprocessor-based, fully electronic logic control system.
- Shuttle search function for quick location of a particular segment in both forward and reverse directions (at about 9 times normal speed with PAL/SECAM tapes and about 7 times normal speed with NTSC tapes.)
- Variable-speed playback in double-speed, slow-motion, freeze-frame and frame-advance modes.
- Fluorescent tube display for indicating tape counting, clock time and programmed timer recording data.
- Multi-programmable timer for presetting up to 8 programmes within a 14-day period.
- Clock/timer memory hold system with a back-up time of about 10 minutes.
- Automatic edit control system which operates on the principle of back-space editing minimizes picture distortion between separately recorded segments.
- Simplified insert editing function which permits different programme segments to be inserted on a pre-recorded tape with minimized distortion at both the start and end of the new, added material.
- Newly-developed brushless, quartz-locked direct-drive drum motor plus motors for capstan, reel, cassette loading and tape loading provide greater stability and higher reliability.
- Simplified mechanism and improved performance in addition to stable tape transport and easy alignment via five-motor system.
- 12-Channel pre-tunable electronic tuner with automatic channel lock mechanism.
- Built-in Dolby* noise reduction system for improved sound quality.
- Advanced mechanisms including cue and counter search for speedy location of a specific programme and tape-end automatic rewind.
- Tape-end indicator warning in two steps.
- Direct camera connection to the front panel connector.
- Sleep timer facility for recording.
- Improved clock accuracy through use of a quartz oscillator.
- Dimmer control for the entire fluorescent display.
- Tape-run indicator.
- Simplified tuning system.

PRECAUTIONS

Handling and storage

- Avoid using the HR-7600MS under the following conditions:
  - extremely hot, cold or humid places,
  - dusty places,
  - near appliances generating strong magnetic fields,
  - places subject to vibrations, and
  - poorly ventilated places.
- Be careful of moisture condensation.
  Avoid using the HR-7600MS immediately after moving from a cold place to a warm place or soon after heating a room which was cold. The water vapor in warm air will condense on the still-cold video head drum and tape guides and may cause damage to the tape and the recorder.
- Handle the HR-7600MS carefully.
  - Do not block the ventilation openings.
  - Do not place anything heavy on the recorder.
  - Do not place anything which might spill and cause trouble on the top cover of the recorder.
  - Use in horizontal (flat) position only.
- In case of transportation,
  - Avoid violent shocks to the recorder during packing and transportation.
  - Before packing, be sure to remove the cassette from the recorder.



Video cassettes

- The HR-7600MS employs VHS-type cassettes only.
  E-240 for 4 hours, E-180 for 3 hours, E-120 for 2 hours, E-60 for 1 hour and E-30 for 30 minutes of PAL or SECAM recording. T-160 for 2 hours and 40 minutes, T-120 for 2 hours, T-60 for 1 hour and T-30 for 30 minutes of NTSC recording.
- Video cassettes are equipped with a safety tab to prevent accidental erasure. When the tab is removed, recording cannot be performed. If you wish to record on a cassette whose tab has already been removed, use adhesive tape to block the hole.
- Avoid exposing the cassettes to direct sunlight. Keep them away from heaters.
- Avoid extreme humidity, violent vibrations or shocks, strong magnetic fields (near a motor, transformer or magnet) and dusty places.
- Place the cassettes in cassette cases and position vertically.

Moisture condensation

- If you pour a cold liquid into a glass, water vapor in the air will condense on the surface of the glass. This is called moisture condensation.
- Moisture condensation on the head drum, one of the most crucial parts of the HR-7600MS, will cause damage to the tape.
- Moisture in the air will condense on the HR-7600MS when you move the unit from a cold place to a warm place, after heating a cold room or under extreme humidity conditions.
- The HR-7600MS is equipped with a moisture condensation prevention circuit which automatically heats the head drum according to the ambient temperature. This circuit operates only when the unit is plugged into an AC outlet, the rear panel MAINS POWER switch is set to ON and the front panel sub-power switch is set to OFF.
- The moisture condensation prevention circuit consumes only a slight amount of power. However, if for some reason you are not using the HR-7600MS for a long period of time, it is advisable to remove the power cord from the AC outlet or set the rear panel MAINS POWER switch to OFF.
- Since the moisture condensation prevention circuit cannot evaporate existing moisture condensation immediately after the power cord has been plugged into the AC outlet, you must allow for about 2 hours if the HR-7600MS is to be used in such areas as would occasion moisture condensation.

Operation

- The cassette can be loaded only when the recorder is powered (with the front panel sub-power switch set to ON). Do not force the cassette into the slot with the power off.
- When the rear panel MAINS POWER switch is set to ON after it has been set to OFF once, the recorder section cannot be powered even though the front panel sub-power switch has been in the ON position. In such a case, first set the sub-power switch to OFF and then set it to ON.
- If you wish to operate the recorder locally after you have switched the power off via the remote control unit, first set the sub-power switch to OFF and then set it to ON again.
- As long as the sub-power switch is set to ON, switching the recorder on or off can be performed via the remote control unit.

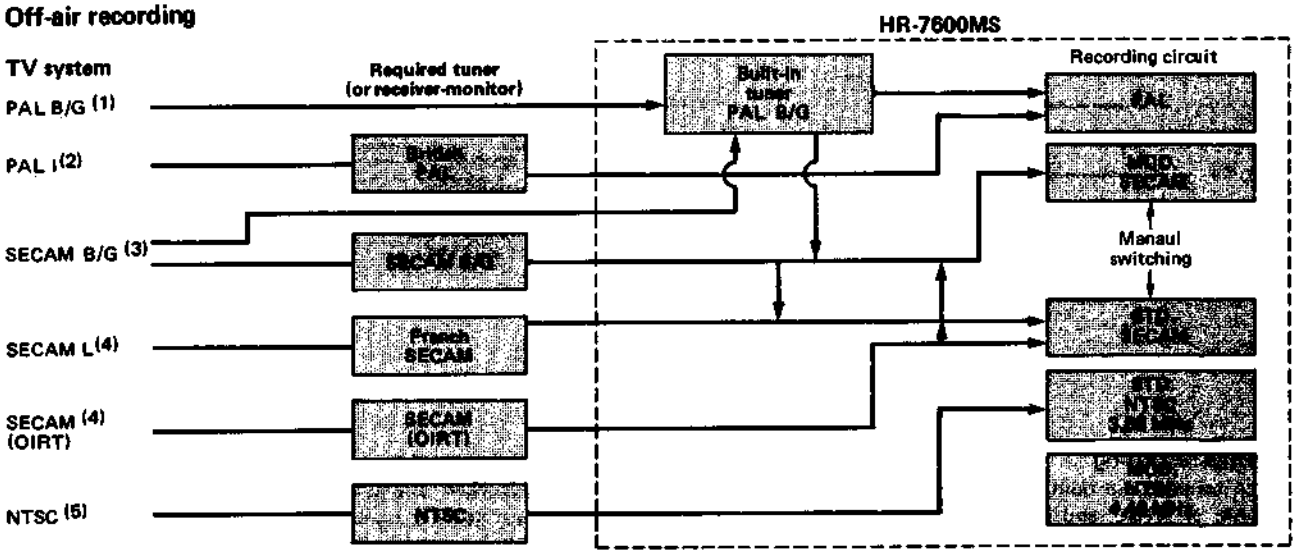
Remote control unit

- Avoid violent shocks, especially take care not to drop the unit.
- Take care not to allow liquid to spill into the unit.
- Do not place heavy objects on the unit, especially be careful not to step on it.
- Avoid leaving the unit in places subject to direct sunlight or extremely high temperatures.

IMPORTANT INFORMATION ON COLOUR SYSTEM SELECTION

The HR-7600MS incorporates the circuitry necessary to record or play back the PAL, SECAM or NTSC signals from any television broadcasting system in the world. To select the right colour system, there are three switches on the HR-7600MS; AUTO/MANU master SYSTEM SELECT switch ⑭, SECAM/PAL/NTSC switch ⑯ and STD/MOD switch ⑮. Generally, when the master switch is set to AUTO, the appropriate system is selected according to the input signal. However, some situations require manual switching. (The circuit in operation is indicated by the 4 COLOUR SYSTEM indicators ⑬.) Please read carefully the following information to ensure correct recording and playback.

Off-air recording



Off-air recording

As illustrated above, the HR-7600MS incorporates 5 different recording circuits to process PAL, MOD. SECAM, STD. SECAM, STD. NTSC and MOD. NTSC signals, enabling broadcasts in any country to be recorded. However, its built-in tuner is for receiving PAL (B/G) broadcasts; to record off the air in countries where television systems other than the PAL (B/G) are employed, it is necessary to connect a tuner (or monitor-receiver) of the corresponding standard.

(1) PAL B/G broadcasts

PAL B/G is the colour television broadcasting system used in most Continental European countries (except France, Luxemburg, and Monaco) and some countries of the Middle East, Africa and Asia. The built-in tuner can be used to record off the air in these countries. Simply set the master SYSTEM SELECT switch to AUTO.

(2) PAL I broadcasts

PAL I is the colour television broadcasting system frequently identified as the British PAL system and used in England, Ireland and some African countries. To record off the air in these countries, a tuner (or monitor-receiver) built to the British PAL system is necessary. The setting of the SYSTEM SELECT switches is identical to that for PAL B/G.

(3) SECAM B/G broadcasts

SECAM B/G is the colour television broadcasting system employed in many countries of the Middle East and Africa. Although SECAM B/G broadcasts can be recorded through a separate tuner (or monitor-receiver) built to this standard, the HR-7600MS's built-in tuner functions sufficiently to receive these broadcasts. Depending on the setting of the STD/MOD switch, either a standard SECAM or modified SECAM tape can be made. Set this switch manually to the appropriate position even when the master SYSTEM SELECT switch is set to AUTO.

(4) SECAM L and SECAM (OIRT) broadcasts

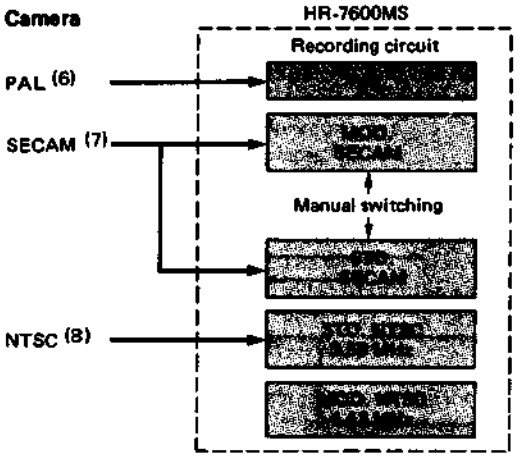
SECAM L is usually identified as the French SECAM system and is employed in France and a few other countries, and the SECAM (OIRT) system is the colour television system of the majority of Eastern European countries. To record off the air in these countries, a tuner (or monitor-receiver) of the corresponding standard is necessary. Both modified SECAM and standard SECAM circuits are involved; select the appropriate position of the STD/MOD switch, even when the master SYSTEM SELECT switch is set to AUTO.

(5) NTSC broadcasts

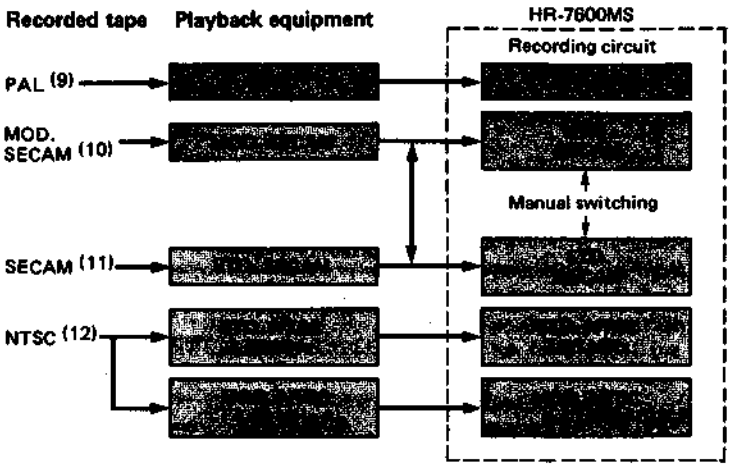
NTSC is the colour television broadcasting system used in the USA, Canada, Japan, several Latin American countries and a few Asian countries. To record off the air in these countries, a tuner (or monitor-receiver) of the NTSC standard is necessary. The broadcast NTSC signal has a subcarrier frequency of 3.58 MHz. Therefore, in the AUTO mode, the standard NTSC circuit is automatically selected.

For further information, consult your nearest JVC dealer.

Camera recording



Tape-to-tape transfer



Camera recording

Video cameras are built to one of the three standards; PAL, SECAM or NTSC, and deliver different signals depending on the standard. To produce tapes with normally recorded signals, use the AUTO mode or set the SYSTEM SELECT switches correctly. For instance, it is impossible to produce NTSC tapes with a PAL camera by manually selecting the NTSC circuit.

(6) PAL cameras
Setting the master SYSTEM SELECT switch to AUTO is sufficient in most cases.

(7) SECAM cameras
Either standard or modified SECAM tapes can be produced, depending on the switch positions.

(8) NTSC cameras
Engaging the AUTO mode automatically selects the standard NTSC circuit.

Tape-to-tape transfer

There are 4 different types of recorded tape, depending on the signal recorded.

(9) PAL tapes
To transfer PAL tapes, a second recorder built to the PAL standard is required to play them. Switch positions are identical to those for recording PAL broadcasts and from a PAL camera.

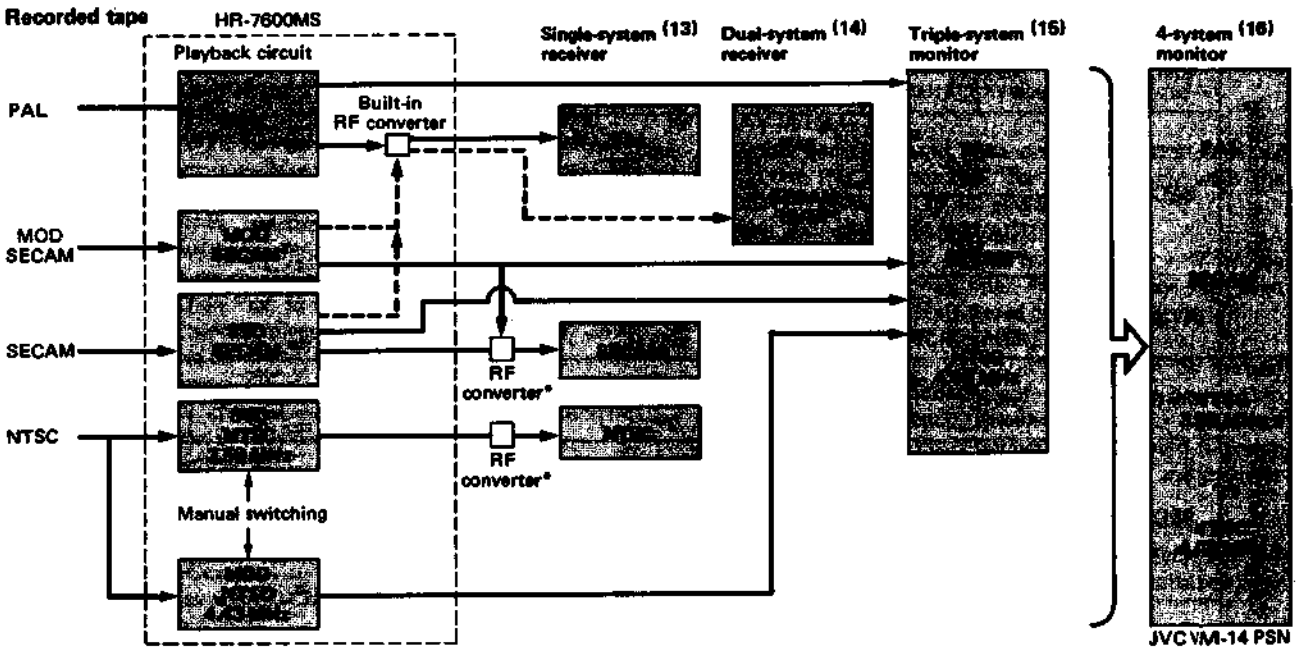
(10) Modified SECAM tapes
Use playback equipment which is capable of processing modified SECAM signals. Depending on what type of tape is desired, either the modified SECAM or standard SECAM circuit of the HR-7600MS can be used. Set the STD/MOD switch manually as required.

(11) Standard SECAM tapes
Use playback equipment which is capable of handling standard SECAM signals. Depending on what type of tape is desired, either the modified SECAM or standard SECAM circuit of the HR-7600MS can be used. Set the STD/MOD switch manually as required.

(12) NTSC tapes
If the playback equipment is built to the NTSC 3.58 MHz standard, the standard NTSC circuit is automatically selected in the AUTO mode. Likewise, if the playback equipment is built to the NTSC 4.43 MHz standard, the modified NTSC circuit is automatically selected in the AUTO mode.

CAUTION
When the HR-7600MS is connected to a multi-system television set, it may happen that no colours appear on the screen if the colour system select switch of the television set is adjusted to the AUTO position. In such a case, change the setting of the colour system select switch of the television set to an appropriate position.

Playback



Playback

The chart for playback and monitoring is separate from the charts for recording. As mentioned above, there are 4 different types of recorded tape. To view video tapes, you may use a TV receiver, or a monitor-receiver or a video monitor, each of which may be built to a specific standard or combination of standards. The chart shows most typical ones of them.

(13) Single-system receiver

Basically, a single-system receiver (or video monitor) enables tapes of the corresponding system to be viewed. The built-in RF converter of the HR-7600MS is built to the PAL system; therefore, to view tapes using a SECAM or NTSC receiver, the built-in RF converter must be replaced with one of the corresponding standard. In such cases, consult a JVC dealer.

Switch positions are identical to those for recording PAL, SECAM or NTSC signals respectively.

(14) PAL/SECAM (B/G) dual-system receiver

Owners of this type of receiver, mostly available in the Middle East, can view PAL and SECAM (both modified and standard) tapes with the built-in RF converter.

(15) PAL/SECAM/NTSC 4.43 MHz video monitor

All tapes can be viewed with this type of monitor. Even in the AUTO mode, select the MOD position of the STD/MOD switch when viewing NTSC tapes.

(16) 4-system video monitor

All tapes can be viewed in the AUTO mode.

*Consult a JVC dealer.

SYSTEM SELECT switches and indicators

(Refer to the chart on the next page.)

- When the master SYSTEM SELECT switch is set to AUTO, the HR-7600MS reads the input signal (or taped signal during playback) and automatically activates the necessary circuit. For MOD SECAM or STD SECAM only, set the STD/MOD switch as required for recording. For playback of NTSC tapes, select the correct position of the STD/MOD switch, depending on the system of the monitor used.
- In the AUTO mode, the indicator corresponding to the automatically selected system lights.
- When the master SYSTEM SELECT switch is set to MANU, the selected circuit is activated regardless of the input signal. The indicator shows the switch positions.
- While recording in the AUTO mode, if the input signal is unstable, substandard or interrupted, the lighted indicator starts flashing.
- If there is no input signal at the initial stage of recording in the AUTO mode, the MANU mode is forcedly engaged and the system corresponding to the switch positions is activated, causing the corresponding indicator to flash.
- NTSC tapes recorded in the LP (Long Play) or EP (Extended Play) mode cannot be played back on this unit. If playback is attempted with such a tape in the AUTO mode, the NTSC indicator will flash.
- In the MANU mode, no indicator flashes in any situation. Playback picture is the reference.
- With a B/W signal input, or when a B/W tape is played back in the AUTO mode, the PAL indicator will light with CCIR signals and the NTSC indicator will light with EIA signals (the MOD indicator will also light when the STD/MOD switch is set to MOD during playback of EIA monochrome tapes.)

SYSTEM SELECT switch positions & Indicators

Use	Source	SYSTEM SELECT switches		Indicators	Remarks
		AUTO mode	MANUAL mode		
Off-air recording	PAL				
	SECAM				To produce modified SECAM tapes.
					To produce standard SECAM tapes.
	NTSC				
Camera recording	PAL				
	SECAM				To produce modified SECAM tapes.
					To produce standard SECAM tapes.
	NTSC				
Tape-to-Tape transfer	PAL				
	SECAM				To produce modified SECAM tapes.
					To produce standard SECAM tapes.
	NTSC (played on STD NTSC machine)				
	NTSC (played on MOD NTSC machine)				
Playback	PAL				
	MOD SECAM				
	STD SECAM				
	NTSC (to be viewed on 3.58 MHz monitor)				
	NTSC (to be viewed on 4.43 MHz monitor)				

*The position of a switch so marked is irrelevant.

GENERAL DESCRIPTION OF CONTROLS, INDICATORS AND CONNECTORS

Front panel

❶ **Sub-power switch**
Set to ON when you use the recorder for recording or playback. Set to TIMER after you have preset the recorder for unattended timer recording, and the power will switch on automatically when the preset time is reached. Set to OFF when you switch off the power from the recorder section. When the switch is set to ON (with the REC SELECT switch ⓱ set to TUNER), the recorder's built-in tuner operates to receive off-the-air TV programmes, while the TV receiver's built-in tuner operates to receive off-the-air TV programmes when the switch is set to OFF. Therefore, in the former case, by setting the TV receiver channel selector to your video channel, you can see pictures on the TV screen that are chosen with the recorder's channel selectors and, in the latter case, you can select any channel with the TV receiver's channel selector for regular TV viewing.

❷ **TAPE RUN indicator**
The LED blinks according to the supply reel speed, in synchronism with the tape counter, showing the condition of tape running.

❸ **Dolby* NR indicator**
This LED lights when the NR switch ⓰ is set to ON.

❹ **TAPE END indicator**
This LED lights when the tape reaches its last portion of about 10 minutes in the Record or Play mode, and then starts flashing about 5 minutes before the end of the tape.

❺ **Cassette loading slot**
When the sub-power switch ❶ is set to ON, the cassette loading mechanism becomes operative. Insert a video cassette with its labelled edge facing toward you. The cassette carriage itself will automatically take control and retract the cassette into the correctly loaded position.

❻ **EJECT button**
Press to eject the cassette.

❼ **X2 button**
Press for double-speed playback after engaging the Play mode.

❽ **SLOW button**
Press for slow-motion playback after engaging the Play mode. To vary the slow-motion speed, turn the SLOW SPEED control knob ⓳ .

❾ **AUDIO DUB button**
Press together with the PLAY button ⓭ to record audio on a pre-recorded tape.

❿ **REC button**
Press together with the PLAY button ⓭ for video and audio recording.

⓫ **STOP button**
To stop the tape.

⓬ **REW/SHUTTLE SEARCH button**
To rewind the tape. This button can be pressed directly from any mode except the Record and Audio Dub modes. During playback, this button enables high-speed playback at about 9 times normal speed in the reverse direction only while it is being pressed, facilitating fast and accurate location of a particular tape section.

⓭ **PAUSE/STILL button**
To stop the tape temporarily. During recording, press this button to avoid recording unwanted material. During playback, press this button to view a still picture.

⓮ **PLAY button**
To play back the tape. Also press this button together with the REC button ⓾ for recording or with the AUDIO DUB button ❾ for audio dubbing.

⓯ **Frame advance button (FR ADV)**
To view the playback picture frame by frame. When the button is pressed once after the Still mode has been engaged, the picture is advanced by one frame.

⓰ **FF/SHUTTLE SEARCH button**
To fast forward the tape. This button can be pressed directly from any mode except Record and Audio Dub modes. During playback, this button enables high-speed playback at about 9 times normal in the forward direction only while it is being pressed, facilitating fast and accurate location of a particular tape section.

⓱ **CLOCK SET button**
Press this button when you adjust the clock for the correct time and the day of the week. For details, see page 17.

⓲ **PROG SET button**
Press this button when you want to pre-programme the timer by entering such data as the day of the week, switch-on time, recording length and the channel number of the TV programme from which you want to record.

⓳ **CLOCK button**
Press this button when you want to change the display mode to the Clock mode from the Programme or Clock Set mode.

⓴ **DIMMER button**
The brightness of the display can be subdued by pressing this button.

㉑ **PROG REPEAT button**
After you have entered all programming data for unattended recording, if you wish the entered data to be kept for repeated recording, press this button. The programme repeat indicator ㉕ will be illuminated.

㉒ **PROG NO button**
Press this button in the Programme Set mode to call up a programme number to which the recording data are to be entered. The number of the called-up programme will be displayed on the PROG NO indicator ㉔ .

㉓ **CANCEL button**
Press this button to cancel or "clear" the preset data after calling up the corresponding programme number on the PROG NO indicator ㉔ .

㉔ **PROG NO indicator**
Numerals 1 through 8 are successively displayed to show which programme is ready for entry. Programmes can be called up by pressing the PROG NO button ㉒ in the Programme Set mode either for entry or for checking.

㉖ **Programme repeat indicator**
When a certain scheduled programme is to be recorded repeatedly week after week or every day indefinitely, the PROG REPEAT button ㉕ is to be pressed. Then this indicator lights to indiçate that the command for "repeat" has been memorized.

㉗ **Week indicator**
The indication "1st" or "2nd" will be illuminated for setting the day for making timer recordings; "1st" stands for the period within one week and "2nd" within the second week from setting.

㉘ **Day indicator**
Both for constant day indication and day presetting for future recordings.

㉙ **Hour digits**

㉚ **Minute digits**

㉛ **COUNTER/REC LENGTH (MIN) digits**
These smaller 4 figures offer three different functions depending on the selected mode.
In the Clock Set mode (with the CLOCK SET button pressed) a two-digit figure is displayed for counting the seconds.
In the Programme Set mode (with the PROG SET button pressed) or the Sleep Timer mode (see the SLEEP indicator ㉜) three digits are displayed and a recording length (or a period of time after which power will be switched off automatically) can be set in minutes (settings in 5-minute increments up to 395).
Except for these three modes, this section functions as a 4-digit tape counter.

㉜ **SLEEP indicator**
When you wish recording to stop after a certain period of time, set the sub-power switch to TIMER after you have started recording. This is referred to as the Sleep Timer mode and the word "SLEEP" will be illuminated. The period of time after which you want recording to stop can be set on the three-digit display, which shows first "060", by pressing the SELECT and SET buttons. (See page 26.)

㉝ **SELECT button**
Press this button to call up the specific item for setting. When the PROG SET button ㉞ is pressed, the item for setting changes each time this button is pressed in the order of "channel", "day", "hour", "minute" and "recording length", and the corresponding portion of the display flashes.
When the CLOCK SET button ㉟ is pressed, the item for setting changes each time this button is pressed in the order of "second", "minute", "hour" and "day", and the corresponding portion of the display flashes.
In the Sleep Timer mode, when the SELECT button is pressed, the REC LENGTH digits start flashing to show that the setting is ready to be made.

㊱ **SET button**
After selecting the item for setting with the SELECT button ㉝ , press this button until the desired indication is reached. Holding it pressed continuously advances the indication rapidly. However, when you select the "second" setting with the SELECT button ㉝ , the second indication is held at "00" when the SET button is held pressed. This is to set the clock time precisely to the second. (See page 17.)

㊲ **Built-in tuner pre-tuning compartment cover**

㊳ **AFT switch**
Set to ON to activate the built-in Automatic Fine-Tuning circuit for fine picture tuning.

㊴ **CH PRESET switch**
Set to ON when you pre-tune the built-in tuner to TV stations in your area. (See pages 15 and 16.)

㊵ **Preset indicator**
This LED lights when the CH PRESET switch ㊴ is set to ON or SKIP and blinks to show that the pre-tuned station has been memorized by pressing the tuning control (labelled PUSH STORE).

㊶ **Band select switch**
This lever-type switch has three positions; U, III and I as illustrated nearby.
Set it to U for tuning to UHF channels 21 to 69.
Set it to III for tuning to VHF channels 5 to 12.
Set it to I for tuning to VHF channels 2 to 4.

㊷ **Tuning control (PUSH STORE)**
Turn in either direction to tune in to each of up to 12 different television stations in your area. After you have pulled in the station, simply press this same control. Then the indicator ㊵ will start blinking. Blinking will stop in a few seconds. This means that the station was stored in memory.

㊸ **Tuning indicator**
The index line moves as the tuning control is turned so as to provide a rough reference concerning the frequency in each selected band.

㊹ **Sub-power indicator**
When the sub-power switch is set to ON, or when the preset switch-on time is reached with the sub-power switch set to TIMER, this indicator lights.

㊺ **Mains power indicator**
This green LED remains lighted as long as the rear panel MAINS POWER switch is set to ON.

㊻ **MIC jack**
Connect a microphone for audio dubbing or mixed recording.

㊼ **SLOW SPEED control**
During slow-motion playback, turn this knob to obtain your desired speed; toward FAST for faster and SLOW for slower speeds.

⑭ **INSERT indicator**
This LED lights when the Insert Edit mode is engaged. (See ㉙ .)

⑮ **TRACKING controls**
Turn the TRACKING control to minimize noise bars, if observed during playback. Use the 2X/STD control during playback at normal and double-speed, and the SLOW control during slow-motion playback.

⑯ **Dolby* NR switch**
Set to ON to activate the built-in Dolby noise reduction system to eliminate tape hiss noise. Recordings made with the NR switch set to ON should be played back with the NR switch set to ON. The sound quality is not improved if non-Dolbyized recordings are played back with the NR switch set to ON, but the tone differs from the original.

⑰ **SEARCH switch**
Two search modes are available; COUNTER search and CUE search.
When the switch is set to COUNTER, the tape stops automatically at the counter reading of nearly "0000" during fast forward and rewind. When the switch is set to CUE, the tape stops automatically at a point where a new recording was made, during either rewind or fast forward by sensing the cue signal. Refer to page 31. Normally set this switch to OFF.

⑱ **SYSTEM SELECT (STD/MOD) switch**
Set this switch to either STD or MOD when recording SECAM signals, depending on the type of tape desired.
When playing back NTSC tapes, set this switch to either STD or MOD depending on the television system of the monitor being used. For more details refer to "Important information on colour system selection" on pages 4 through 7.

⑲ **SYSTEM SELECT (SECAM/PAL/NTSC) switch**
Use this switch to manually select the appropriate system only when the master SYSTEM SELECT switch ㉕ is set to MANU. For more details refer to "Important information on colour system selection" on pages 4 through 7.

⑳ **INSERT button**
Press this button for insert editing. See page 29.

㉑ **V HOLD control**
For adjusting the picture during slow-motion, still-frame and double-speed playback, if the TV receiver's V-hold control fails to correct a phenomenon caused by insufficient vertical lock.

㉒ **COUNTER RESET button**
Press this button to reset the counter to "0000".

㉓ **Infrared beam receiving window**
For receiving signals from the infrared remote control unit.

㉔ **COLOR SYSTEM indicators**
These four indicators show the selected system, according to the detected input signal (in the AUTO mode), or to the switch positions (in the MANU mode). For more details refer to "Important information on colour system selection" on pages 4 through 7.

㉕ **SYSTEM SELECT (AUTO/MANU) switch**
This is a master switch for selecting the television system. First set this switch to either AUTO or MANU depending on the required mode. When the MANU mode is selected, set the other two SYSTEM SELECT switches manually as required. For more details refer to "Important information on colour system selection" on pages 4 through 7.

㉖ **REC SELECT switch**
For selecting the recording input signal.
Set to TUNER when recording signals coming from the built-in tuner (TV programmes).
Set to AUX when recording signals coming from the units connected to the rear panel VIDEO IN and AUDIO connectors.
Set to CAMERA when recording signals coming from a camera connected to the front panel CAMERA connector ㉗.

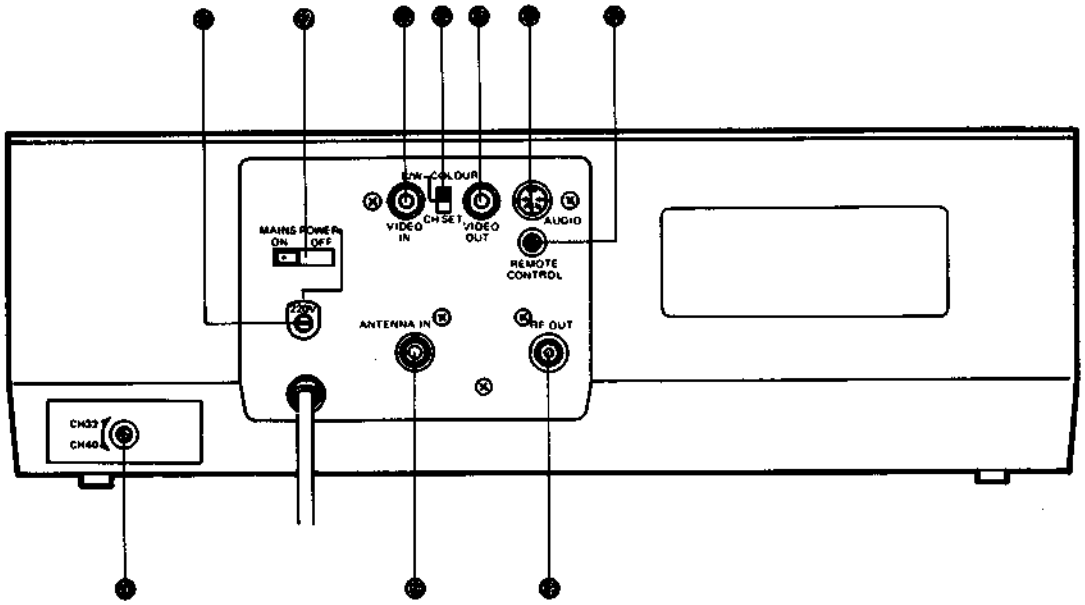
㉗ **CAMERA connector**
Connect a JVC video camera directly to this connector using a 10-pin camera cable.
Caution: Other brands of cameras and some JVC cameras may not be electronically compatible, even though the same type of connector is used. Consult your dealer.

㉘ **Channel indicators**
The numeral corresponding to the selected channel is illuminated.

㉙ **Channel select buttons**
Press to select the specific channel from which you want to record.

*Noise reduction system manufactured under license from Dolby Laboratories Licensing Corporation.
Dolby and the double-D symbol are trademarks of Dolby Laboratories Licensing Corporation.

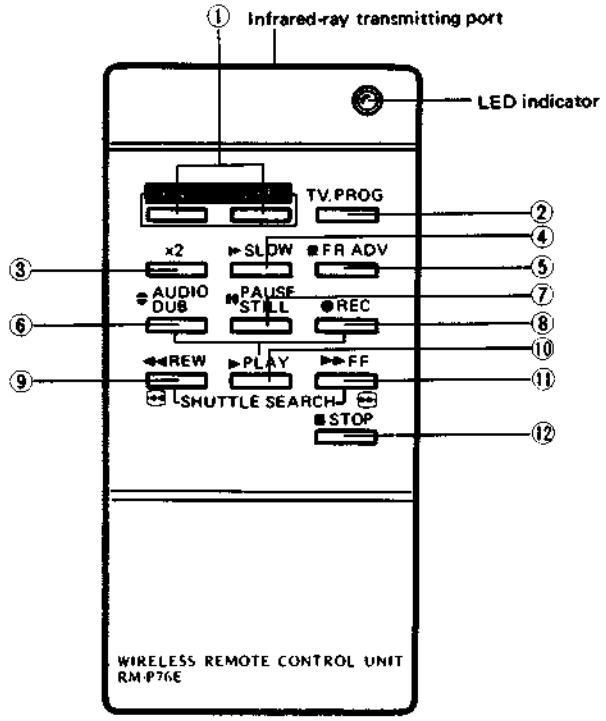
Rear Panel



- **Voltage selector**
  The preset voltage is indicated in the window. If it differs from your local power line voltage, reset it. See "POWER SYSTEM" on page 1.
- **MAINS POWER switch**
  Switching ON applies mains power to the set. To switch off the set completely, set the MAINS POWER switch to OFF. This switches off the timer/clock circuit and cancels all the preset programming data after the memory backup time (about 10 minutes) has elapsed. This also switches off the built-in aerial circuit so that the TV receiver connected to the HR-7600MS will not be able to receive off-the-air TV programmes for good viewing condition. Normally set this MAINS POWER switch to ON.
- **VIDEO IN connector**
  Connect the video output of other video equipment such as another video tape recorder.
- **Video mode select switch**
  This applies to both recording and playback.
  COLOUR: Set to this position when the input or playback video signal is in colour.
  B/W: Set to this position when the input or playback video signal is monochrome.
  CH SET: Set to this position when tuning your TV receiver for the "Video Channel".
- **VIDEO OUT connector**
  Video signals being recorded or played back are available from this connector.
- **AUDIO input/output DIN socket**
  Connect a tape recorder or other audio sources or connect the audio output of other video sources for recording. Also, audio signals being recorded or played back are available from the output terminals of this DIN socket.
- **REMOTE CONTROL connector**
  The RM-P73U wired remote control unit, optionally available, can be connected to this terminal.
- **RF OUT connector**
  Connect to the antenna connector of a TV receiver through the aerial cable (provided).
- **ANTENNA IN connector**
  Connect an aerial to this connector.
- **RF converter frequency adjustment screw**
  To re-adjust the output frequency of the built-in RF converter. (See page 14.)

Infrared remote control unit

The infrared remote control unit provided, lets you control 16 functions from your viewing position.



① **ON/OFF buttons**
To switch power on or off for the recorder.
Notes
- These buttons are not to switch the power circuit of the remote control unit itself on or off. The remote control unit is always ready to operate. It consumes power only at the time the buttons are being pressed.
- In order for the remote control unit to be able to switch the power for the recorder on or off, the recorder's sub-power switch should be in the ON position.

② **TV. PROG button**
Press this button a number of times until the desired channel number is illuminated on the recorder's channel indicator.

③ **X2 button**
To play back the tape at a speed twice the normal. Before pressing this button, press the PLAY button.

④ **SLOW button**
To view slow-motion playback. Before pressing this button, press the PLAY button.

⑤ **FR ADV button**
To advance the playback picture frame by frame in the Still mode.

⑥ **AUDIO DUB button**
Press together with the PLAY button ⑩ for audio dubbing.

⑦ **PAUSE/STILL button**
To stop the tape temporarily during recording or playback.

⑧ **REC button**
Press together with the PLAY button ⑩ for starting recording.

⑨ **REW/SHUTTLE SEARCH button**
To rewind the tape or to play back the tape at 9 times normal speed in the reverse direction.

⑩ **PLAY button**
To play back the tape.

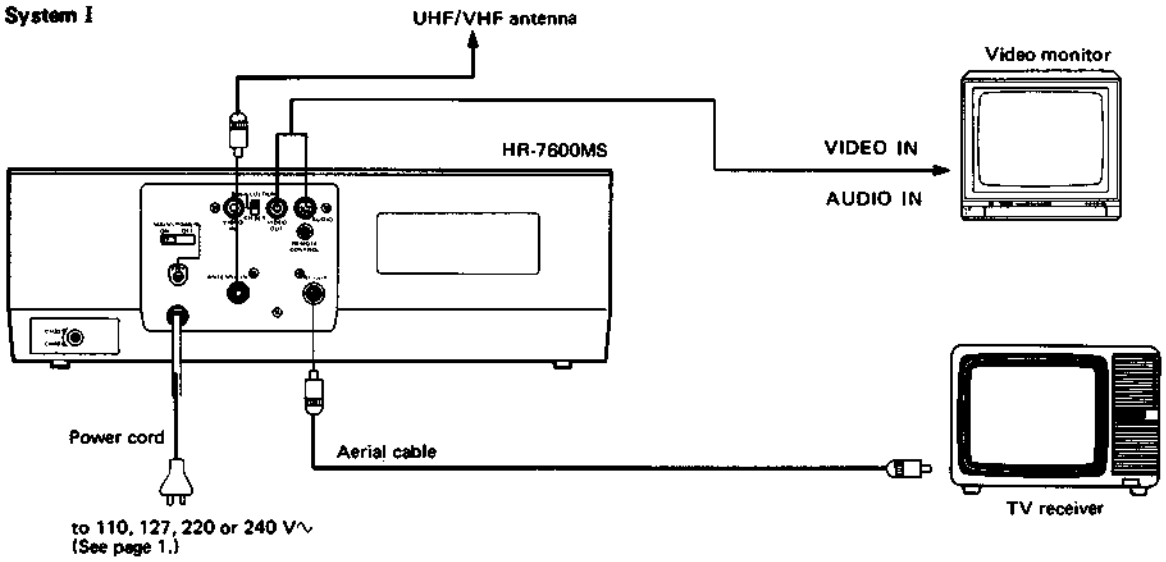
⑪ **FF/SHUTTLE SEARCH button**
To rewind the tape or to play back the tape at 9 times normal speed in the forward direction.

⑫ **STOP button**
To stop the tape.

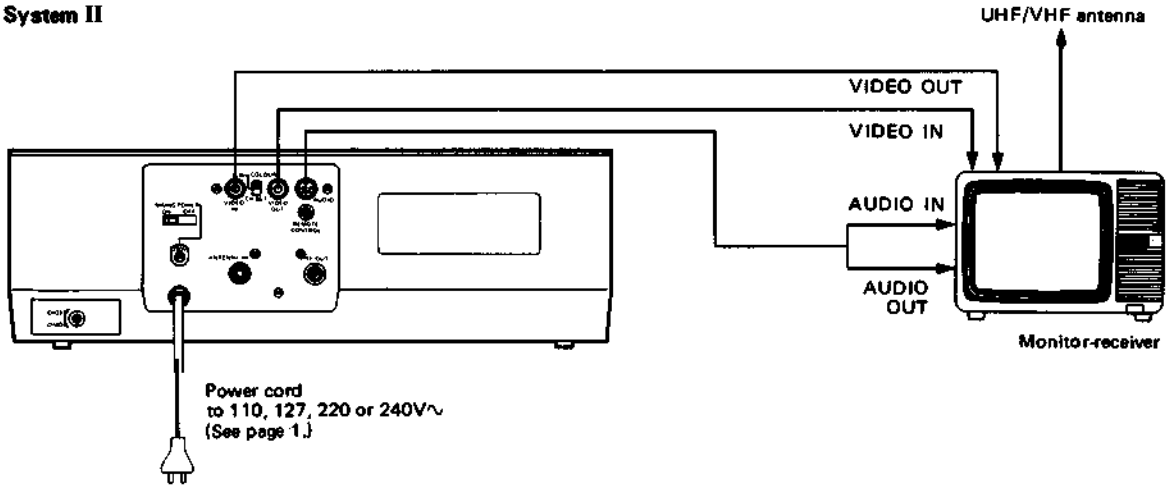
PART II PREPARATIONS

HOW TO CONNECT THE HR-7600MS TO YOUR TV SET

System I



System II



System I

When the built-in PAL tuner is appropriate for your area

1. Remove the antenna cable from your TV receiver and reconnect it to the HR-7600MS as illustrated. The HR-7600MS is then ready to record off-air TV programmes.
2. Connect the HR-7600MS to the TV receiver using the aerial cable provided. The TV receiver is then ready to receive TV broadcast programmes as well as video cassette programmes from the HR-7600MS.
3. When you use a video monitor for playback, connect the VIDEO OUT and AUDIO connectors of the HR-7600MS to the VIDEO IN and AUDIO IN connector of the video monitor.

Note

Even when you are not using the HR-7600MS, the rear panel MAINS POWER switch should be set to ON in order to be able to view TV broadcast programmes with this connection.

System II

When a separate tuner (or monitor-receiver) is required

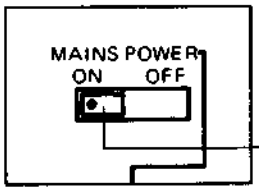
1. Connect the HR-7600MS to a monitor-receiver as illustrated. This connection enables you to receive TV broadcasts with the tuner in the monitor-receiver, and record them with the HR-7600MS.

HOW TO SET YOUR VIDEO CHANNEL

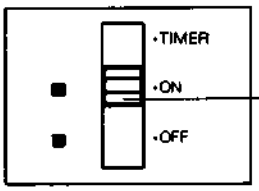
The RF converter built into the HR-7600MS conforms to the PAL B/G system. When you view video programmes on a TV receiver through this RF converter, follow the instructions below.

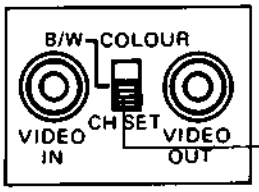
Viewing video cassettes means that the TV receiver receives video playback signals just like it receives broadcast signals. For this purpose, the TV receiver must be set to a specific channel. That channel is "YOUR VIDEO CHANNEL". And it is the built-in RF converter that determines your video channel, since the RF converter permits playback of video and audio recordings through a TV receiver. The signals from the RF converter are viewed through a vacant channel not used for broadcasting. The converter channel of all units is set to UHF channel 36 prior to shipment. Setting your TV receiver to UHF channel 36 may provide video playback. However, to obtain the best possible reproduction on your TV receiver, accurate adjustment to the RF converter output is required.

Procedure

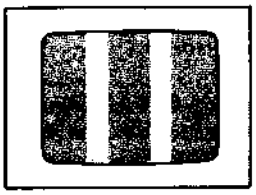


1. Set the rear panel MAINS POWER switch ⓰ to ON and set the sub-power switch ❶ on the front panel to ON.



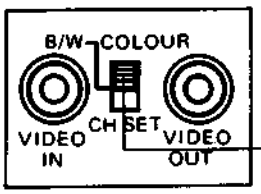


2. Set the video mode switch ⓱, located on the rear panel, to CH SET (Channel Setting).



3. Adjust your TV receiver in the vicinity of UHF channel 36 until you bring in the two white signal bars on the screen as illustrated.

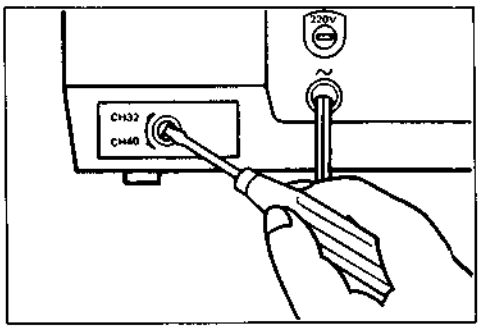
This setting is now the VIDEO CHANNEL of the TV receiver to which the HR-7600MS is connected.



4. Reset the video mode switch ⓱ to COLOUR.

Notes

- When you adjust your TV receiver to channel 36 for video playback, if some interference noise is seen on the screen because of broadcasts on neighbouring channels or if your preset UHF broadcasts should be affected in picture quality, it is necessary to shift slightly the RF converter output frequency from that of channel 36.

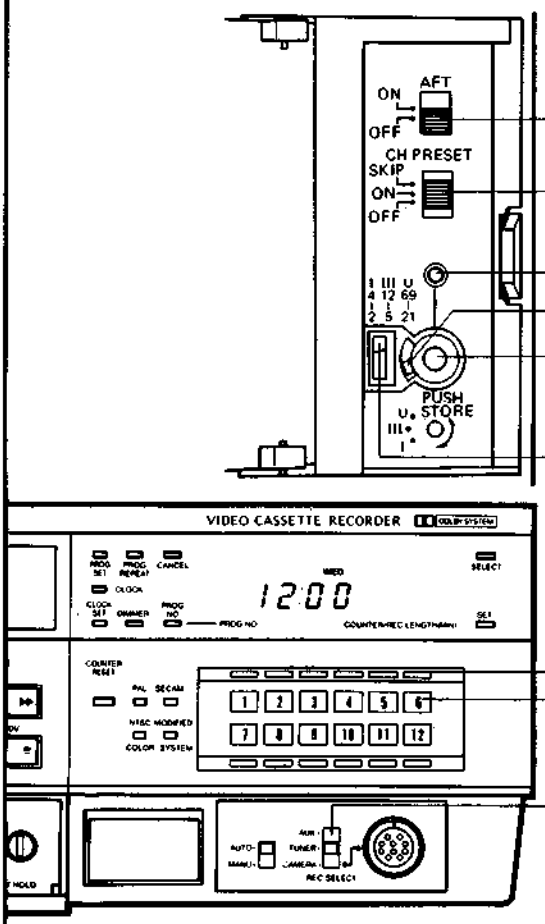


For this purpose, insert a small screwdriver into the RF converter frequency adjustment screw ⓲ and adjust it in minute steps. Then tune the TV receiver once again until a clear picture is obtained.
This adjustment requires extreme precision and must be done with the utmost care. We recommend that you consult your JVC dealer for making this adjustment.

- Be sure to set the video mode switch to COLOUR after VIDEO CHANNEL tuning has been completed.
- No signal is available from the VIDEO OUT terminal while the Channel Setting signal is being used.
- If a prerecorded VHS cassette is available, TV adjustment for VIDEO CHANNEL setting is also possible using it to obtain a playback picture. Insert the cassette and operate the HR-7600MS for playing back the cassette (See Part III "How to load and unload the video cassette" and "How to play back the video cassette".) Then tune the TV receiver to obtain clear pictures and sound while monitoring the playback picture on the TV screen.
- If your TV receiver is not provided with an AFC circuit, perform fine tuning of the TV receiver when you are actually viewing video cassettes.

HOW TO PRE-TUNE THE BUILT-IN TUNER

Basic guidelines



㊺ AFT switch
For automatic fine picture tuning.

㊻ CH PRESET switch
Engages or disengages the Channel Preset mode. Also used to preset the channels to be skipped.

㊼ Indicator
Lights in the Channel Preset mode and blinks when the tuned-in station is memorized.

㊽ Band select switch
To select the TV station frequency band.

㊾ Tuning control
Used to tune in to a desired TV station. Pressing this control permits the pre-tuned TV station to be held in memory.

㊿ Tuning indicator
Moves to indicate where you are in the selected frequency band.

(51) Channel select buttons

(52) Channel indicators

(53) REC SELECT switch

The built-in tuner of the HR-7600MS has a capacity of receiving 12 different channels. You can preset any TV station in your area to any one of these 12 channels. It is you who determine what TV station to specify for what channel number.

The basic procedure is: select a channel number, tune in to a station and store the information. Then you can easily call up any preset station simply by pressing the corresponding channel select button.

The built-in tuner conforms to the PAL B/G system. When you use the built-in tuner to record TV broadcasts, perform pre-tuning following the instructions in this chapter.

Procedure

1. Set the sub-power switch ❶ to ON.
2. Switch the power of the TV receiver ON.
3. Set the REC SELECT switch ㊸ to TUNER.
4. Adjust the TV receiver's channel to your VIDEO CHANNEL. (See page 14.)
   - Now a TV programme, if being received by the built-in tuner, will be shown on the screen of the TV receiver. And now you are ready to preset the built-in tuner to TV stations in your area while monitoring the picture on the TV screen.
5. Open the pre-tuning control compartment cover.
6. Set the CH PRESET switch ㊻ to ON.
   The indicator ㊼ will light. And the AFT (Automatic Fine Tuning) circuit will be switched off automatically regardless of the setting of the AFT switch ㊺ .
7. Press the channel select button which you have chosen to allocate to the station to be pre-tuned in. The channel number corresponding to the selected channel will be illuminated.

8. Set the band select switch ⑱ as required.
   Set to I when tuning in to VHF channels 2 through 4.
   Set to III when tuning in to VHF channels 5 through 12.
   Set to U when tuning in to UHF channels 21 through 69.
9. Turn the tuning control ⑲ while observing the TV screen to tune in to a desired station.
   - Turning the tuning control in either direction moves the tuning indicator in the corresponding direction.
10. To obtain the best possible picture, make further adjustments.

Striped picture

Clean picture

   - Turn the tuning control first until you get the striped picture and then slowly turn, little by little, to clear up the picture.
11. Push in the same tuning control ⑲ to store the information.
   - The indicator will start blinking. Blinking will stop in a few seconds. This means that the station was stored in memory.
   - If you should happen to turn the tuning control while the indicator is still blinking, the channel lock mechanism will engage and, therefore, if you press another channel select button it will have no effect. To correct this situation in order to proceed with presetting other channels, press the tuning control once again and wait for the blinking of the indicator to stop so that the preset information for the channel you selected last will be stored.
12. Perform the same adjustments, steps 7 through 11, for each of the other channels.
13. If everything is alright, return the CH PRESET switch ⑯ to OFF.
14. Make sure that the AFT switch ⑰ is set to ON.
15. Close the compartment cover.

Notes
- Normally set the AFT switch ⑰ to ON.
  If neighbouring channels are close to each other, set this switch to OFF.
- If the picture is still not clear, perform fine tuning on your TV receiver.
- Distorted pictures or sound will be recorded if fine tuning has not been properly performed. Exercise care with this adjustment since the recorded picture and sound cannot be adjusted later.

Skipping unused channels

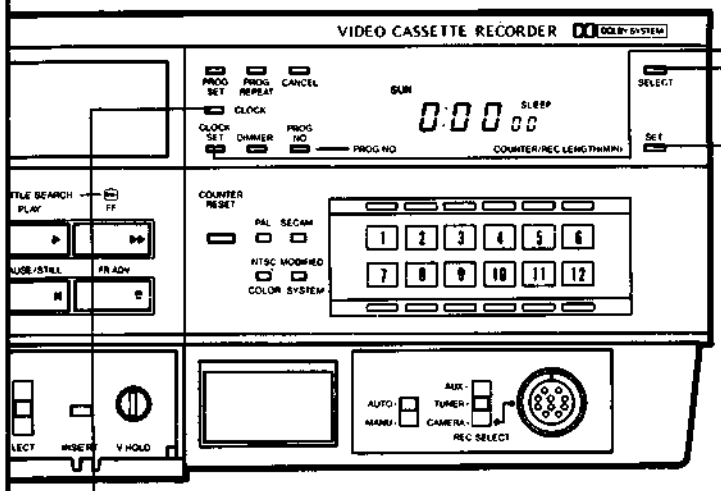
Though 12 channels are available for presetting to desired TV stations, you may not need all 12 channels. In such cases, unused channels can be skipped so that only preset channels are operable. This function is especially convenient when you select the channel via the remote control unit which has only one button for channel selection. If some channels are skipped, you don't have to press the CHANNEL button of the remote control unit a number of times to reach your desired channel.

To skip the channels, proceed as follows:
1. Select the channel you want to skip by pressing the corresponding channel select button ⑳ .
2. Set the CH PRESET switch ⑯ to SKIP.
   - The indicator will light.
3. Push in the tuning control ⑲ .
   The indicator will blink momentarily and remain lit after that. This means that the information for skipping that channel has been stored in memory.
4. Select another channel that you wish to skip and repeat the same procedure as above.
5. Return the CH PRESET switch ⑯ to OFF.

Note
- It is possible to restore the skipped channels for presetting to another TV station whenever necessary. For this purpose, set the CH PRESET switch to ON and press the channel select button corresponding to the channel you want to restore. Then tune in to your desired station and store it in the same manner as described above.
- Channel 1 cannot be skipped.
- When a channel which has been already preset to a station is skipped, the stored information for that channel will be cancelled. Therefore, if you wish to restore the skipped channel, you should perform the channel presetting procedure for that channel once again.

HOW TO SET THE CLOCK

Basic guidelines



⑭ **CLOCK SET button**
Engages the Clock Set mode.

⑮ **SELECT button**
Selects the item for setting; "second", "minute", "hour" and "day".

⑯ **SET button**
Enters the required data for each selected item.

You need only four controls to set the clock.
First, CLOCK SET and last, CLOCK.
In between, only SELECT and SET.
Select the item (the called-up item will flash to indicate that it is ready to be set) and set it by entering the correct data.

⑲ **CLOCK button**
Engages the Clock mode.

Procedure

When the HR-7600MS is plugged into an AC outlet and the rear panel MAINS POWER switch is turned ON, the display shows a flashing "SUN 0:00". Now you are ready to set the built-in clock to the correct local time.

1. Press the CLOCK SET button ⑭, and the "second" digits will start counting while flashing.
2. Press the SELECT button ⑮, and then the "minute" digits will start flashing.
3. Press the SET button ⑯ until the correct minute indication is displayed.
4. Press the SELECT button ⑮, and then the "hour" digits will start flashing.
5. Press the SET button ⑯ until the correct hour indication is displayed.
6. Press the SELECT button ⑮, and then the "SUN" indication will start flashing.
7. Press the SET button ⑯ until the correct day is displayed.
8. Press the SELECT button ⑮, and then the "second" digits will start flashing.
9. Hold the SET button ⑯ pressed, and the seconds will be reset to and held at "00".
   - If the "second" indication is over "30" (from 30 to 59), pressing the SET button will reset the "second" digits to "00" but will give one increment to the minute indication (for example, 10'35" – 11'00").
10. Release the button at the exact instant of the reference time signal (radio, telephone, TV, etc.) and the clock will be set accurately to the correct local time.
11. Press the CLOCK button ⑲ to return to the Clock mode. No item will be flashing any more. And the "second" digits will turn off.

Notes

- Holding the SET button pressed for more than 1 second continuously advances the minute, hour or day indication automatically. Pressing it once advances the indication in single increments only.
- During the Clock Set mode, if no command is entered within two minutes, the Clock mode will be automatically engaged. If you have not yet made the clock setting, press the CLOCK SET button once again to engage the Clock Set mode.
- Clock setting is impossible with the sub-power switch ⑪ set to the TIMER position.

Power failure indicator

- If you find "SUN 0:00" flashing on the display, it means that a power failure has occurred and time-keeping has not taken place since that time.
- Correct the time indication following the above procedures.
- If the period of power outage is within about 10 minutes, correct time-keeping continues when power is reapplied.
- During this 10-minute period, the built-in memory back-up capacitor maintains time-keeping and preset timer memory, though the display blacks out.
- The memory back-up capacitor is automatically being recharged as long as the rear panel MAINS POWER switch is set to ON. It takes about 30 minutes to recharge this capacitor from its fully discharged condition.

Readjusting the clock time

- If a slight increase or reduction of time indication is found, readjust the clock following the same procedure as for time setting.
- Remember that the seconds from 0 to 29 will be reset to "00" when the SET button is pressed and the seconds from 30 to 59 will be reset to "(+1'):00".

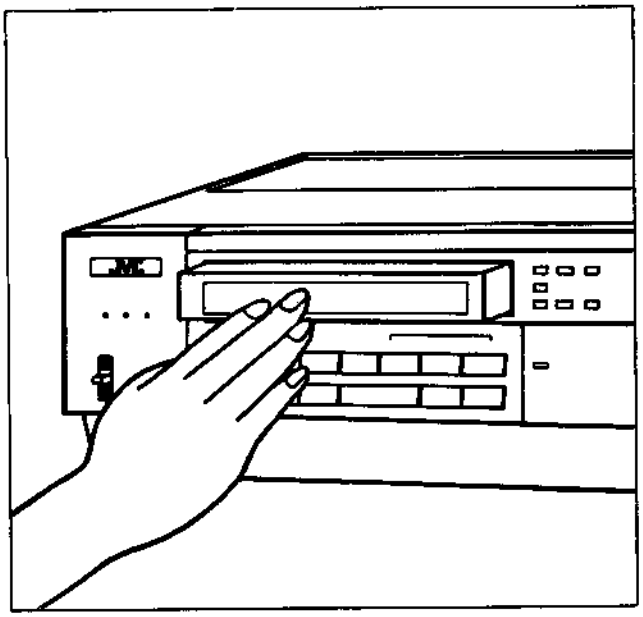
PART III

BASIC OPERATION

HOW TO LOAD AND UNLOAD THE VIDEO CASSETTE

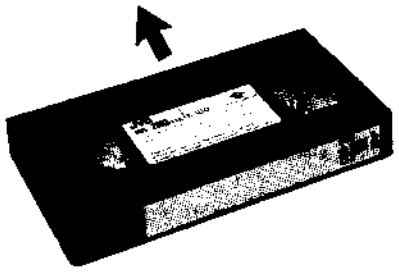
Caution

- Since the HR-7600MS employs a motorized cassette loading system, loading and unloading the cassette are only possible when the power is applied to the recorder section. Do not force the cassette into the cassette loading slot while the front panel sub-power switch is set to OFF.
- Do not attempt to pull out the cassette once automatic loading has started.



Loading

1. Set the sub-power switch ❶ to ON.
2. Insert a cassette with its labelled side facing you. The cassette will automatically be retracted and loaded in the correct position.
   - The STOP indicator will be flashing during automatic loading of the cassette and, when it has been correctly loaded, will remain lighted.
   - The automatic loading mechanism will operate only when the cassette is inserted correctly.
   - If loading into the correct position is not executed, the cassette will automatically be ejected after about 6 seconds.

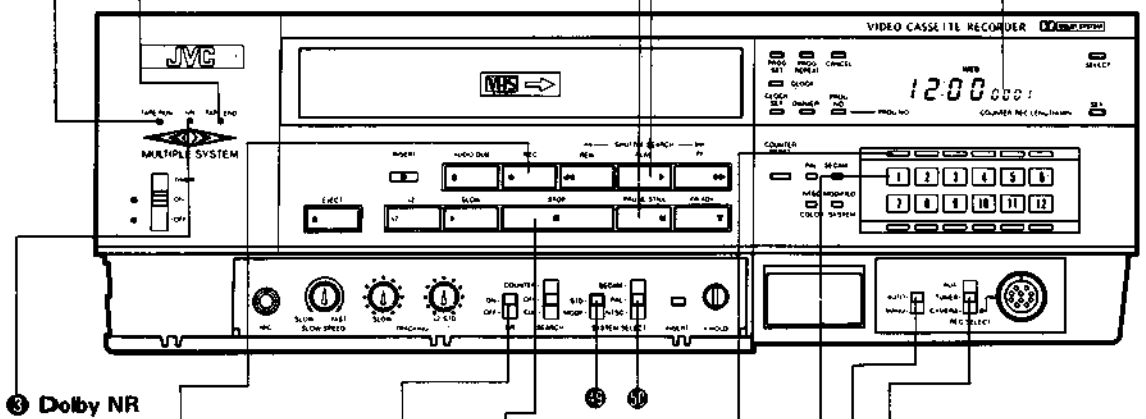


Unloading

1. Press the EJECT button ❻ . The cassette will automatically be ejected. Then, simply remove it from the cassette loading slot.
   - The EJECT indicator will be flashing during automatic unloading of the cassette and then turn off upon completion of ejection.
   - The EJECT button can be pressed during any mode except Record and Audio Dub.

HOW TO RECORD A TV PROGRAMME WHILE WATCHING IT

Basic guidelines



❷ TAPE RUN indicator
Flashes to show that the tape is running.

❹ TAPE END indicator
Lights 10 minutes before the end of the tape and starts flashing 5 minutes before the end of the tape.

⓭ PAUSE/STILL button
To stop the tape temporarily.

⓮ PLAY button
To start tape transport.

⓰ Tape counter
When the sub-power switch is set to ON, this 4-digit tape counter is illuminated.

❸ Dolby NR indicator

⓯ REC button
To start recording.

❽ STOP button
To stop recording.

⓱ NR switch
To improve sound quality.

⓳ ⓴ REC SELECT switch
Setting to TUNER activates the built-in tuner.

㉒ Channel indicators
The selected channel will be illuminated.

㉑ Channel select buttons
For selecting the specific channel from which you want to record.

Now you are ready to record your favourite TV programmes. Guidelines for doing this: receive the desired TV programme with the built-in tuner and operate the tape section.

Confirm the settings of the SYSTEM SELECT switches ⓳, ⓴ and ㉓ by referring to the chart on page 7.

This section describes the recording procedure when the built-in tuner (which conforms to the PAL B/G system) is used. If a separate tuner (or monitor-receiver) is used to record broadcast programmes, see the next page.

Preparation

1. Set the sub-power switch ❶ to ON.
2. Load a cassette.
3. Set the REC SELECT switch ⓳ to TUNER.
4. Set the channel selector of your TV receiver to your VIDEO CHANNEL. (See page 14.)
5. Press the channel select button corresponding to the channel you wish to record.
   - The picture you are going to record will appear on the TV screen, but recording is not yet taking place.
   - If a clear picture or correct colour is not obtained, tuning may not have been done accurately. Re-perform tuning in the manner described in "HOW TO PRE-TUNE THE BUILT-IN TUNER" on pages 15 and 16.

Recording

1. Press the REC and PLAY buttons ⓫ ⓬ simultaneously. Recording will start.
   - When these buttons are pressed, first the tape is pulled out from the cassette and loaded around the tape transport mechanism. During this period, the PLAY indicator will flash.
   - Then recording starts while the tape is running. In this state, both the REC and PLAY indicators remain lighted.
2. Set the NR switch ⓯ to ON if you wish to make hiss-less recordings.
   - The Dolby NR indicator ⓭ will light.
3. To skip recording part of the programme, press the PAUSE/STILL button ⓮ . The tape will stop while remaining in the Record mode.
   - The PAUSE/STILL indicator will light with also the REC and PLAY indicators remaining lighted.
4. To release the Pause mode, press the PLAY button ⓬ .
5. To stop recording, press the STOP button ⓭ .
   - When the STOP button is pressed, first the tape is unloaded from around the tape transport mechanism. During this period, the STOP indicator will flash. When the tape has returned into the cassette, the indicator remains lighted.
   - When the end of the tape is reached during recording, the tape is automatically rewound to the beginning and stops. During rewinding, the REW indicator lights and, when the tape reaches the beginning, the STOP indicator lights.

Notes

- For using the tape counter, see page 31.
- If the REC button cannot be pressed, check to see if the cassette safety tab has been removed. (See page 3.)
- Sound from a microphone connected to the MIC jack can be mixed with the TV sound being recorded.
- The Pause mode is released automatically after about 6 minutes in order to prevent tape damage and the Stop mode is engaged.
- The built-in automatic channel lock mechanism prevents the selected channel from being altered during recording. Therefore, if you wish to change the channel during recording, first engage the Pause mode and then select a different channel.
- For your reference, this automatic channel lock mechanism operates in the following cases:
  (1) when the sub-power switch is in the OFF position,
  (2) in the Programme Set mode,
  (3) when the REC SELECT switch is in the AUX or CAMERA position,
  (4) when a tape is being played back, and
  (5) in the Record mode.

  Because of this, when you set the sub-power switch to ON after it has been set to OFF, the same channel which was selected last will be received. The same applies to case (3). When you return the REC SELECT switch to TUNER from AUX or CAMERA, the last channel is memorized.

HOW TO RECORD ONE TV PROGRAMME WHILE WATCHING ANOTHER

A programme, not being viewed, can be recorded while you enjoy viewing another programme. This permits the recorded programme to be played back later at your convenience. The recording procedures are exactly the same as when recording a TV programme while watching it.

The key points to be remembered are:

- Select the channel you wish to record with the recorder's channel select buttons ⓰ .
- Select the channel you wish to view with the TV receiver's channel selector.

HOW TO RECORD A TV PROGRAMME FROM A MONITOR-RECEIVER

- Set the REC SELECT switch ⓯ to AUX.
- Select the channel you wish to record with the monitor-receiver's channel selector.

Other steps are identical to those for recording with the built-in tuner. However, when using a separate monitor-receiver, it is not possible to record one programme while watching another.

HOW TO PLAY BACK THE VIDEO CASSETTE

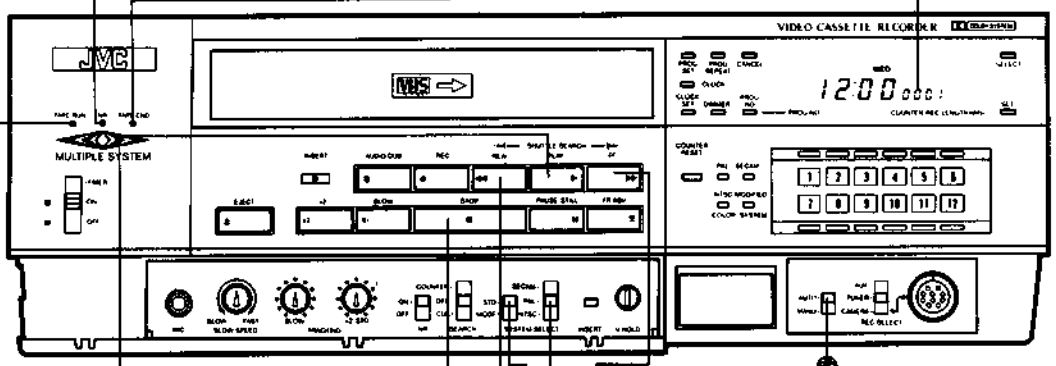
Basic guidelines

❷ TAPE RUN indicator
Flashes to show that the tape is running. Its flashing interval is accelerated or decelerated according to the tape supply reel speed.

❸ TAPE END indicator
Lights 10 minutes before the end of the tape and starts flashing 5 minutes before the end of the tape.

⓫ Tape counter
See page 31.

❸ Dolby NR indicator



❽ PLAY button
To start playback.

❶ STOP button
To stop playback.

❷ REW/SHUTTLE SEARCH button
To rewind the tape or to play back the tape at about 9 times normal speed in the reverse direction to locate the desired tape section.

❼ FF/SHUTTLE SEARCH button
To fast forward the tape or to play back the tape at about 9 times normal speed in the forward direction to locate the desired tape section.

Confirm the settings of the SYSTEM SELECT switches ❺, ❻ and ❼ by referring to the chart on page 7.

Procedure

1. Set the sub-power switch ❹ to ON.
2. Load a cassette.
3. Set the channel selector of your TV receiver to your VIDEO CHANNEL. (See page 14.)
   When using a monitor-receiver, select the A/V channel specified on the model being used.
4. Press the PLAY button ❽ .
5. Make sure that the Dolby NR indicator ❸ lights if you play back tapes recorded with the NR switch ON. If it does not light, open the sub-panel cover and set the NR switch ❾ to ON.
6. To stop playback, press the STOP button ❶ .
   - When the end of the tape is reached during playback, the tape is automatically rewound to the beginning.

Rewinding and fast forwarding the tape

- The same button is used for rewind and reverse shuttle search. To rewind the tape, press the REW/SHUTTLE SEARCH button ❷ in the Stop mode. When the beginning of the tape is reached, the Stop mode is automatically engaged. If you wish to stop rewinding midway, press the STOP button ❶ .
- The same button is used for fast forward and forward shuttle search. To fast forward the tape, press the FF/SHUTTLE SEARCH button ❼ in the Stop mode. When the end of the tape is reached, the tape automatically starts rewinding. If you wish to stop it midway, press the STOP button ❶ .

Shuttle search function

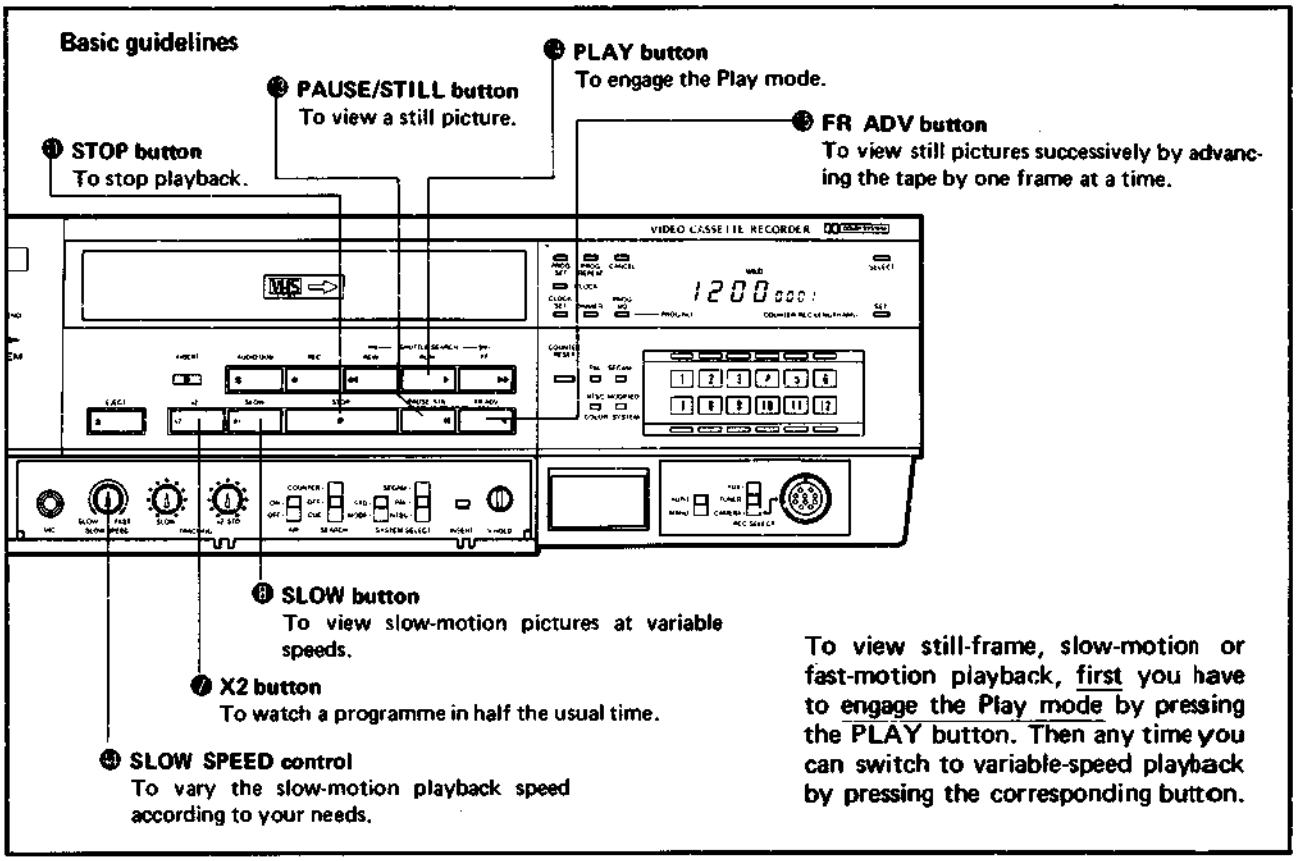
The unique "shuttle search" function permits you to reach quickly your desired tape section while following the playback picture on the TV screen. The tape speed is about 9 times the normal and "search for a scene" is possible in both directions; either forward or reverse. This is why this function is named "shuttle search".

- After engaging the Play mode, press the FF/SHUTTLE SEARCH button ❼ or REW/SHUTTLE SEARCH button ❷ depending on the direction in which you are going to search for a particular scene and hold it until your desired scene appears on the screen. Releasing the button restores the normal Play mode.
- Since the audio circuit is switched off in this mode, you are free from "unintelligible" sound.

Notes

- For usage of the tape counter and SEARCH switch, refer to page 31.
- If the playback picture contains noise bars, adjustment with the TRACKING controls may be necessary. Refer to page 31.
- NTSC tapes recorded in the LP (Long Play) or EP (Extended Play) mode cannot be played back on this unit. If playback is attempted with such a tape in the AUTO mode, the NTSC indicator will flash.

HOW TO ENJOY VARIABLE-SPEED PLAYBACK



Double-speed playback

- After engaging the Play mode by pressing the PLAY button ⓮, press the X2 button ⓰. The X2 indicator will light and playback will take place at a speed twice the normal.
- To restore the normal playback speed, press the PLAY button ⓮.
- This function will be especially convenient for quickly running through longer tape sections while at the same time following the contents until you reach the actual section you want to view at the normal speed.
- No audio is heard in the Double-speed mode.

Slow-motion playback

- After engaging the Play mode by pressing the PLAY button ⓮, press the SLOW button ⓫. The SLOW indicator will light and playback will take place at a slower speed.
- You can increase or decrease the slow-motion speed according to your needs. For this purpose, after engaging the Slow mode by pressing the SLOW button ⓫, open the sub-control panel cover and turn the SLOW SPEED control ⓱ in either direction until you get the desired speed.
- The slow-motion speed is variable from approx. 1/5 to 1/25 the normal.
- No audio is heard in the Slow-motion mode.
- The Slow-motion mode is released automatically after about 6 minutes in order to prevent tape damage and the Stop mode is engaged.

Still-frame playback

- After engaging the Play mode by pressing the PLAY button ⓮, press the PAUSE/STILL button ⓭. The PAUSE/STILL indicator will light and the picture will "freeze" instantly.
- To release the Still mode, press the PLAY button ⓮.
- The Still mode is released automatically after about 6 minutes in order to prevent tape damage and the Stop mode is engaged.

Frame advancing

- While in the Still mode, you can advance the picture frame by frame.
- Pressing the FR ADV button ⓯ once, advances the picture by one frame.
- This function will be convenient to search for the precise instant of a crucial scene you wish to view.
- No indicator lights in the FR ADV mode.

Notes

- During still-frame or slow-motion playback, the TV picture might vibrate horizontally. To reduce such vibrations, we recommend that you employ the AV channel for video playback if your TV receiver is provided with such. If the vibrations are rather excessive, consult your local JVC dealer.
- For tracking adjustment during double-speed or slow-motion playback, refer to page 31.

PART IV

ADVANCED USAGE

HOW TO PRESET THE TIMER FOR UNATTENDED RECORDING

Basic guidelines

⑭ PROGRAM NO indicator
Displays the called-up programme number.

⑮ Programme repeat indicator

⑯ Week indicator

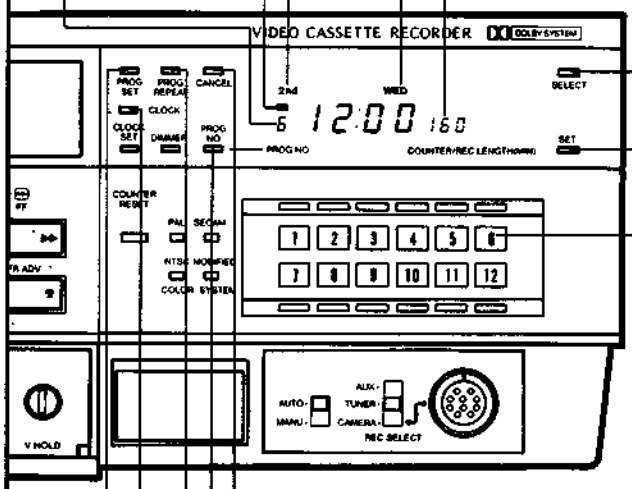
⑰ Day indicator

⑱ COUNTER/REC LENGTH (MIN) digits
Displays the recording length in minutes in the Programme Set mode.

⑲ SELECT button
Selects the item for setting; "channel", "week", "day", "hour", "minute" and "recording length".

⑳ SET button
Sets the required data for each called-up item.

㉑ Channel indicators
The selected channel to be recorded later will flash.



㉒ CANCEL button
To cancel the preset data.

㉓ PROG NO button
To call up a programme memory on which recording data are to be entered.

㉔ PROG REPEAT button
For repeated pre-programmed recording.

㉕ CLOCK button

㉖ PROG SET button
Engages the Programme Set mode.

> Timer recording is possible only when the built-in tuner (conforms to the PAL B/G system) is used.

The built-in 2-week/8-programme programmable timer permits recording of preset channels on preset days, at preset times for preset lengths while you are away. First preset the programmable timer and then operate the recorder section for unattended recording (this procedure is described in the next chapter). Guidelines for presetting the timer: Call up a programme number among 1 through 8 and enter the programming data with the SELECT and SET buttons.

Procedure

1. Press the PROG SET button ㉖
   - The display will be changed from the Clock mode to the Programme Set mode.

- When the PROG SET button is pressed, programme No. 1 is always called up first. If you wish to change the programme number, press the PROG NO button ㉓ .

2. Press the SET button ⑱ until the TV programme channel number you want to record is illuminated.
   - In the Programme Set mode, the channel select buttons are inoperative.
3. Press the SELECT button ⑰ , and then "1st SUN" will start flashing.
4. Press the SET button ⑱ to specify the day.
   - Pressing it once advances the indication by one day and holding it pressed advances the indication rapidly.
   - The sequence of indication changing is: from SUN to SAT of the 1st week, then from SUN to SAT of the 2nd week, then everyday from SUN to SAT of the 1st week, then returning to the original condition.
5. Press the SELECT button ⑰ , and then the "hour" digit will begin flashing.
6. Press the SET button ⑱ to obtain a desired hour indication.
7. Press the SELECT button ⑰ , and then the "minute" digits will begin flashing.
8. Press the SET button ⑱ to specify a desired minute indication.
9. Press the SELECT button ⑰ , and the REC LENGTH digits will begin flashing.
10. Press the SET button ⑱ to obtain a desired recording length.
    - The recording length can be set within 395 minutes in 5-minute steps.
11. Now you have finished presetting the timer for program "1". If you need to enter another preset programme, press the PROG NO button ⑰ , and "2" will be displayed on the PROGRAM NO indicator ⑯ for the next programme setting. You can follow the same procedure as instructed above.
12. When you have finished all necessary presettings to future programmes, set the CLOCK button ⑲ to return to the Clock mode.
13. After having programmed the timer, be sure to load a cassette, make sure that the REC SELECT switch ⑨ is set to TUNER and set the sub-power switch ⑩ to TIMER following the instructions given below.

Repeating the preset programmes

- Normally the preset data are cleared after a recording has been made accordingly. However, if you wish to hold the preset data in memory in order for recordings to be made repeatedly according to this same data (for example, at the same time on the same day every week), press the PROG REPEAT button ⑮ . The programme repeat indicator ⑮ will light.

Cancelling the preset programmes

- The preset programmes can be cancelled by pressing the CANCEL button ⑰ after calling up the corresponding programme number on the display.
- If you wish to cancel all preset data for programmes 1 through 8, press the CANCEL button ⑰ while simultaneously holding the PROG NO button ⑰ . Then all programmes will be cleared and programme No. 1 will be displayed.

Notes

- During the Programme Set mode, if no command is entered within two minutes, the Clock mode will be automatically engaged. If you have not yet finished setting the programme, press the PROG SET button once again.
- The preset data can be called up any time for checking by engaging the Programme Set mode and calling up the relevant programme number.
- If you wish to change the preset data partially, press the SELECT button in the Programme Set mode until the corresponding item starts flashing on the display and enter the new data by pressing the SET button.
- It is impossible to alter the programmed data (except the recording length) during actual timer recording.
- The recording length can be changed even during timer recording by using the SELECT and SET buttons in the Programme Set mode.
- If a power failure should occur (and last longer than about 10 minutes), not only time-keeping stops (see page 17), but also all the preset data will be cancelled. A flashing SUN 0:00 indicates this after power has been reapplied. In such cases, first correct the time indication and then re-enter the programming data.

HOW TO SET THE RECORDER FOR UNATTENDED RECORDING

After having programmed the timer, prepare the recorder section for unattended recording.

1. Set the sub-power switch ⑩ to ON.
2. Load a cassette.
   - Make sure that the tape length is sufficient for the sum of your intended recordings.
   - Make sure that the safety tab of the cassette is in place.
3. Make sure that the REC SELECT switch ⑨ is set to TUNER.
4. Set the sub-power switch ⑩ to TIMER.
   - If the safety tab of the cassette has been removed, the cassette is automatically ejected when the sub-power switch is set to TIMER.

Now preparations for unattended recording are complete; when the preset switch-on time is reached, recording will start automatically. There is no need to press the REC and PLAY buttons to engage the Recording Standby mode.

Notes

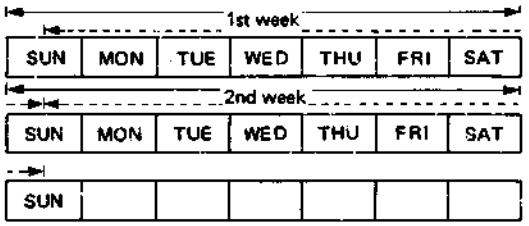
- Tape loading starts 10 seconds before the preset switch-on time and recording starts exactly at the preset time.
- If the end of the tape is reached during timer recording, the auto rewind mechanism does not function and the cassette is automatically ejected.
- After the unattended recording has been made, set the sub-power switch to OFF.

FOR A BETTER UNDERSTANDING OF THE PROGRAMMABLE TIMER

Two-week timer

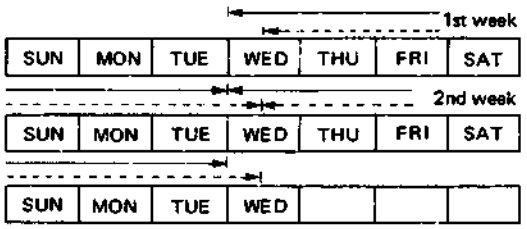
"Two-week" presetting capacity means that you can "reserve" recordings on any one of 14 days in advance including the day of setting.

If the current day of setting is Sunday:



- In this situation, there may be no possibility of confusion in setting the day.
- Namely, the "1st MON" is Monday of the current week and the "2nd MON" is Monday of the next week. The same applies to other week days.
- Regarding Sunday, there are two different cases; one is that you are going to set the timer to a time before the current time of setting and the other is that the preset time is a time after the current time of setting.
- In the former case, the "1st SUN" is the next Sunday and the "2nd SUN" is the Sunday after next.
- In the latter case, the "1st SUN" is the current Sunday and the "2nd SUN" is Sunday of the next week.

If the current day of setting is Wednesday for example:



- Remember that the "1st MON", "1st TUE" and so on . . . mean the first coming Monday, the first coming Tuesday, and so on, and not Monday of the current week.
- Similarly, the "2nd MON", "2nd TUE" and so on . . . are the second coming Monday, the second coming Tuesday, and so on, and not Monday or Tuesday of the next week.
- If you are on Wednesday for example, and wish to record something on Tuesday of the next week, the preset data should be "1st.TUE". To record on Thursday of the next week, set "2nd THU".
- Regarding Wednesday, the same as mentioned about Sunday on the left applies.

8-programme timer

"8-programme" presetting capacity means that you can have 8 separate programme entries which contain different programming data. Because of this capacity, you can even "reserve" 8 different TV programmes, either on the same day or on different days.

Each programme (No. 1 through No. 8) entry contains information on "TV programme channel number", "day", "switch-on time", "recording length" and "either single or repeat".

Example of the contents of one programme entry:

Programme number	TV programme channel number	Day	Switch-on time	Recording length	Repeat
2	12	1st WED	2:30	30 min.	-

Variety of setting possibilities

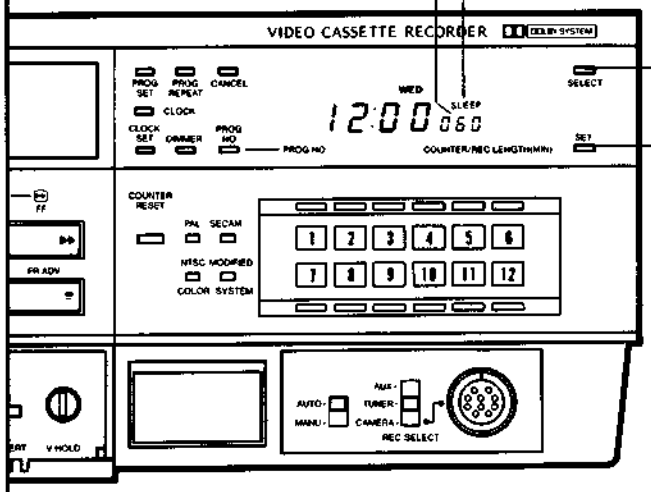
- You can set for some day of the 1st week or the 2nd week.
- You can set for one day of every week by first setting that day of the 1st week and pressing the PROG REPEAT button.
- You can set for one day of every week starting from the second week by first setting that day of the 2nd week and pressing the PROG REPEAT button.
- You can set for all days of the 1st week. For this setting, obtain the indication "1st SUN MON TUE WED THU FRI SAT", and recordings will be repeated at the same time everyday for one week.
- You can set for all days week after week. For this setting, first obtain the indication as mentioned above and then press the PROG REPEAT button. And recordings will be made everyday week after week.
- All the above applies for all 8 programme entries.

Programme priority

- If you have preset two programmes for the same day and the same switch-on time, the setting corresponding to the smaller programme number has priority.
- If two programmes have preset times which overlap, the earlier-started programme will be interrupted by the latter one.
- When a certain preset time is reached in the Sleep Timer mode, the Sleep Timer mode has priority.

HOW TO USE THE SLEEP TIMER FACILITY

Basic guidelines



⑭ **COUNTER/REC LENGTH (MIN) digits**
For setting the period of time after which the power is automatically switched off.

⑮ **SLEEP indicator**
The word "SLEEP" is illuminated in the Sleep Timer mode.

⑰ **SELECT button**
Enables the REC LENGTH digits to flash so that they can be changed.

⑱ **SET button**
Sets the required time for the Sleep Timer mode to continue.

The built-in sleep timer facility allows recording to stop automatically after a certain period of time. Start recording in an ordinary manner, then shift the sub-power switch to TIMER and set the switch-off time.

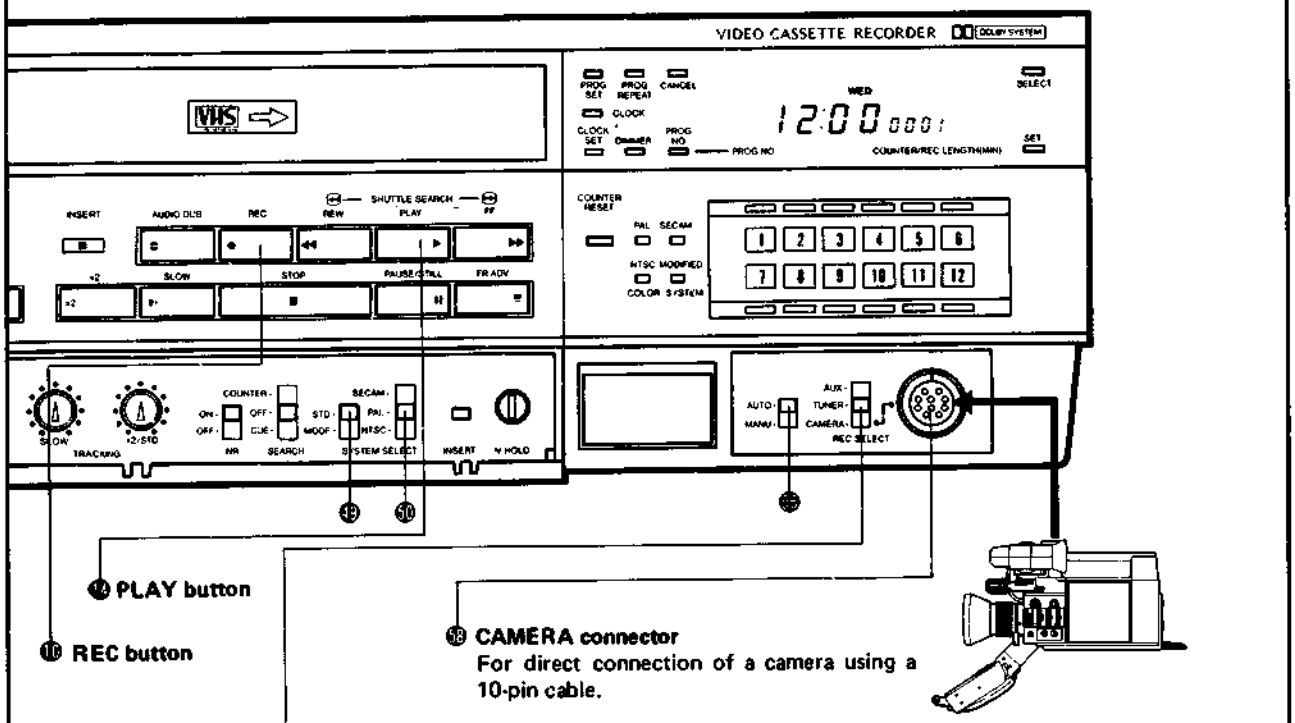
Procedure

1. Set the sub-power switch ❶ to ON.
2. Load a cassette.
   - Make sure that the safety tab of the cassette is in place.
3. Start recording in the manner described before.
4. Shift the sub-power switch ❶ to TIMER.
   - The SLEEP indicator ⑮ will be illuminated and the figures "060" will appear on the REC LENGTH indicator. This means that power will be switched off automatically after 60 minutes.
5. If you want to change the length of time, press the SELECT button ⑰.
   - The digits will start flashing.
6. Press the SET button ⑱ to obtain a desired length of time.
   - The length of time can be set within 395 minutes in 5-minute steps.
7. Press the SELECT button ⑰ once again, and the digits will stop flashing and the Sleep Timer mode will be engaged.

After a preset time, power will be switched off automatically. If the end of the tape is reached during recording in the Sleep Timer mode, the automatic rewind mechanism does not function and the cassette is automatically ejected.

HOW TO RECORD WITH A VIDEO CAMERA

Basic guidelines



⑫ PLAY button

⑯ REC button

⑱ **CAMERA connector**
For direct connection of a camera using a 10-pin cable.

⑲ **REC SELECT switch**
Setting to CAMERA enables signals from the camera connected to the CAMERA connector to be recorded.

When a camera is connected to the CAMERA connector and the REC SELECT switch is set to CAMERA, it is powered through the recorder and scenes being shot by the camera will appear on the TV screen.

Procedure

1. Connect a camera.
2. Press the sub-power switch ⑪ to ON.
3. Switch on the TV receiver.
4. Set the TV receiver's channel selector to your VIDEO CHANNEL.
5. Set the REC SELECT switch ⑲ to CAMERA.
   - You can monitor the scenes being shot by the camera.
6. Load a cassette.
7. Press the REC and PLAY buttons ⑯ ⑫ simultaneously. The recorder enters the Recording Standby mode.
   - When a camera is connected, starting or stopping of the tape is remote-controlled by the camera. Therefore, pressing the REC and PLAY buttons does not yet start the tape-running operation.
8. Operate the camera's start/stop switch. Now recording will start.

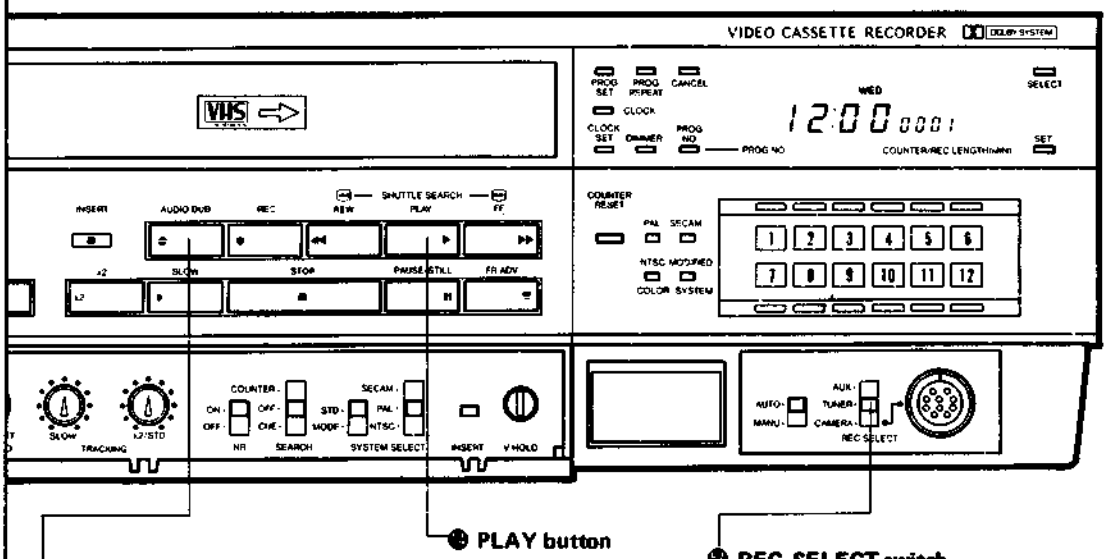
Notes

- If feedback noise (whistling or howling) is heard from the TV receiver, reduce the volume or move the microphone, either external or built within the camera, farther away from the TV receiver.
- Power to the camera is switched on or off with the sub-power switch or by using the built-in timer.
- With some cameras, their battery warning indicator may flicker, however, no problem occurs with recording as long as the picture being monitored on the TV screen appears normal.

Confirm the signal system of the camera being used and set the SYSTEM SELECT switches ⑬, ⑭ and ⑮ correctly to suit the camera.

HOW TO PERFORM AUDIO DUBBING

Basic guidelines



⑨ **AUDIO DUB button**
To start audio dubbing.

⑩ **PLAY button**

⑰ **REC SELECT switch**
Setting to AUX enables signals from audio equipment connected to the rear panel AUDIO connector to be recorded.

Audio dubbing means recording a sound track on a pre-recorded cassette. Sound from a source connected to the rear panel AUDIO connector, or from a microphone connected to the front panel MIC jack, or a mixture of the two can be recorded. The previously recorded sound is erased and replaced with a new sound track by audio dubbing.

Procedure

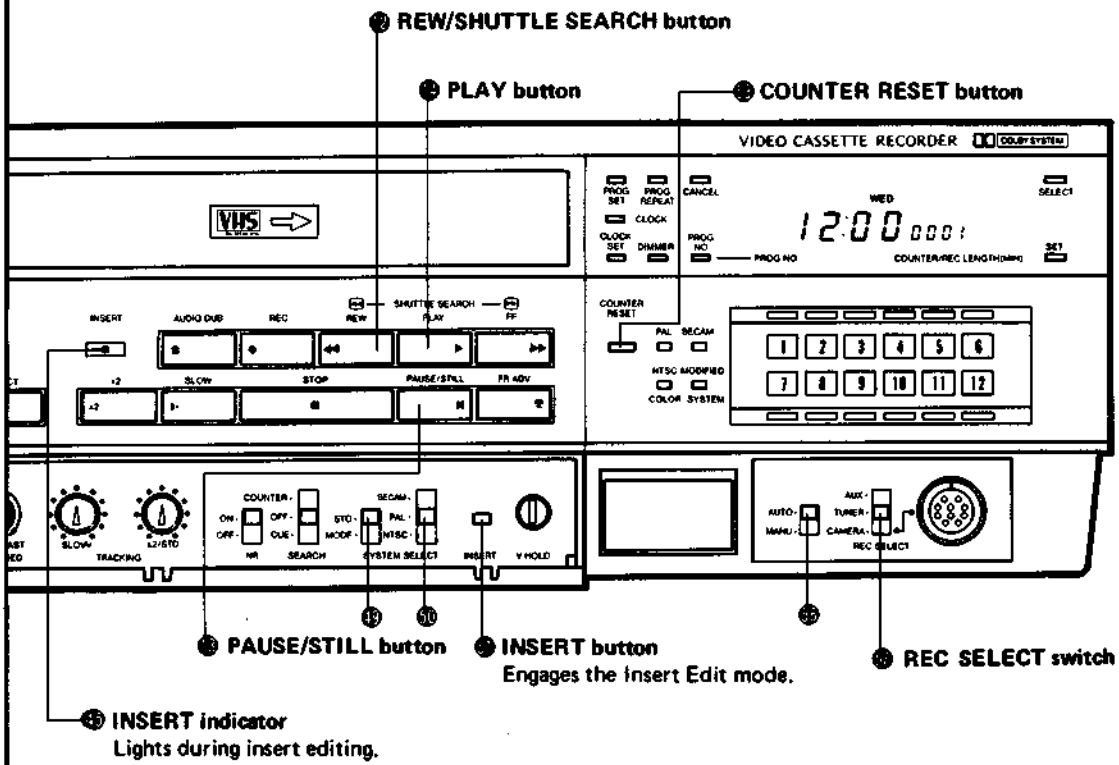
1. Load a pre-recorded cassette.
2. Set the TV receiver's channel selector to your VIDEO CHANNEL to monitor the playback picture while dubbing audio.
3. Set the REC SELECT switch ⑰ to AUX.
   - If you record sound only from the microphone, this switch has no effect and may be in any position.
4. Press the AUDIO DUB and PLAY buttons ⑨ ⑩ simultaneously. The AUDIO DUB and PLAY indicators will light and audio dubbing will start.

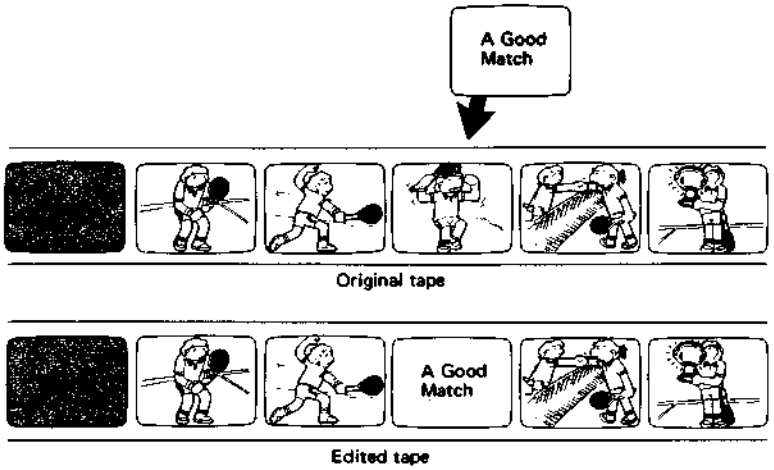
Notes

- Use a high-impedance microphone.
- If whistling or howling is heard during audio dubbing, reduce the TV volume or move the microphone farther away from the TV. Recording is being performed even if sound is not heard from the TV receiver. If you want to monitor the sound being recorded, connect an earphone to the TV receiver.
- The pause function facilitates audio dubbing. First play back the pre-recorded tape and press the PAUSE/STILL button at the point from which you wish to start audio dubbing. If necessary, adjust the point by using the FR ADV button. Then press the AUDIO DUB and PLAY buttons simultaneously. This permits you to start audio dubbing exactly at the right point.
- Even though you are playing back the tape in the Double-Speed (X2) mode, normal speed is automatically resumed when the Audio Dub mode is engaged.

HOW TO PERFORM INSERT EDITING

Basic guidelines



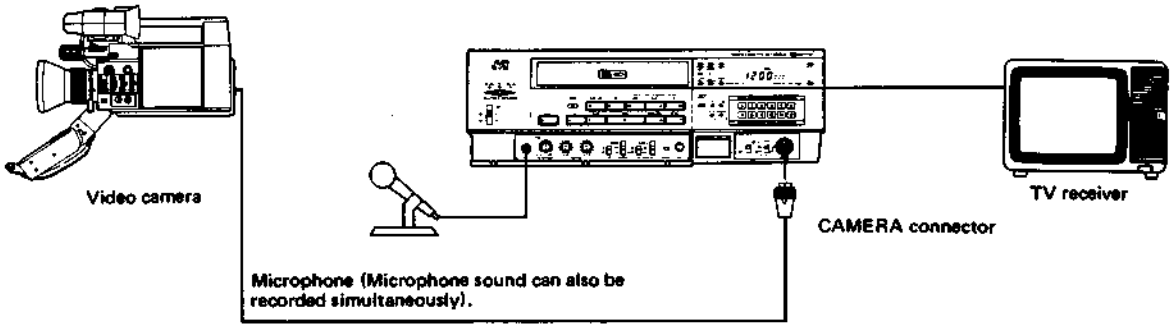


Insert editing means recording a new scene into a section of pre-recorded tape so that a part of the original recording can be replaced with a new one without excessive picture distortion at edit-in and edit-out points.

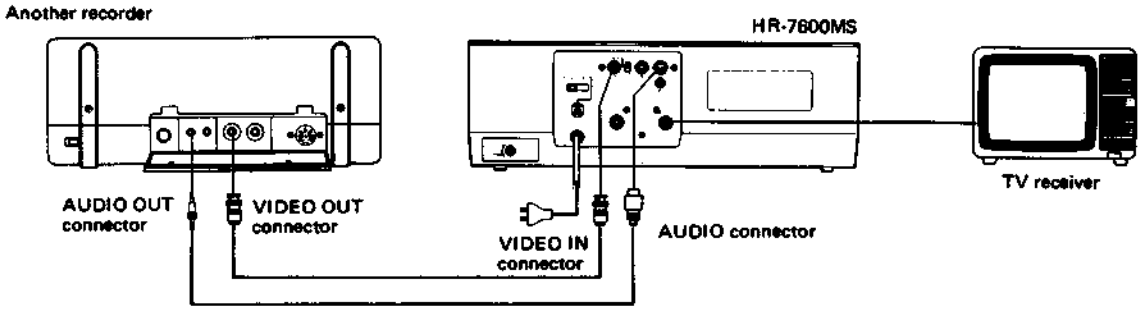
New video and audio signals to be inserted can come either from a video camera or another video cassette recorder, or even from the built-in tuner.

Connections

For inserting video and audio signals from a camera connected to the CAMERA connector.



For inserting video and audio signals from another video cassette recorder.



Satisfactory insert editing is possible only when the new signal to be inserted and the signal pre-recorded on the tape have the same signal system.

Procedure

1. Load a pre-recorded cassette.
2. Set the TV receiver's channel selector to your VIDEO CHANNEL to monitor the playback picture.
3. Set the REC SELECT switch ● as required.
   AUX: To insert programmes from a different tape.
   TUNER: To insert TV programmes from the built-in tuner.
   CAMERA: To insert camera signals from a camera connected to the CAMERA connector.
4. Play back the tape to determine the edit-out point (the end of the tape section to be replaced).
5. Press the PAUSE/STILL button ● at the edit-out point.
6. Reset the tape counter to "0000" by pressing the COUNTER RESET button ● .
7. Run the tape backwards by pressing the REW/SHUTTLE SEARCH button ● to determine the edit-in point (the beginning of the tape section to be replaced).
8. Press the PAUSE/STILL button ● at the edit-in point.
9. Press the PAUSE/STILL button ● and the INSERT button ● simultaneously. This engages the Insert Standby mode in which the input signal can be monitored on the TV screen; the still picture changes into the input signal that you are going to record. The input sound signal can also be monitored. The INSERT indicator ● will light.
10. Operate the source equipment properly.
    - Play back on another recorder the tape programme to be inserted.
    - Operate the camera so that it is in the running lock mode.
    - Select the channel to be recorded with the corresponding channel select button.
11. Press the PLAY button ● to start insert editing. Now video and audio signals will be recorded simultaneously.
12. At the counter reading of "0000", recording will stop automatically and the INSERT indicator will turn off.
13. The tape will continue running in the Play mode.

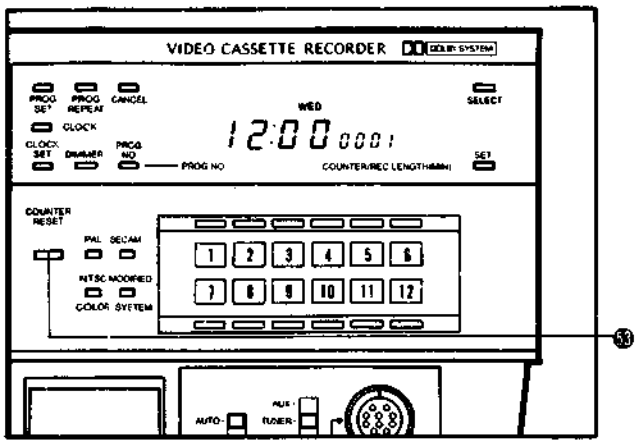
Notes

- Do not use the STOP button to stop insert editing. If you press the STOP button, the tape stops and the Insert Edit mode is cancelled.
- If there happens to be a non-recorded segment on the pre-recorded tape on which you are going to insert new material, the picture will be distorted temporarily at this segment during playback.
- The insert edit is not of the professional type. Therefore the results very much depend on the previously recorded signal, whether colours are stable or fluctuate slightly. This is not due to any defect of the unit.
- Do not repeat insert editing onto the same section of the tape, as this will degrade the picture quality.

PART V

ADDITIONAL FACILITIES

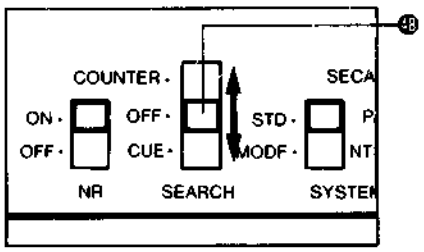
HOW TO USE THE TAPE COUNTER



The tape counter is helpful for tape indexing. When the sub-power switch ❶ is set to ON, the display shows the tape counter beside the clock time.

- The tape counter functions in all tape modes.
- Pressing the COUNTER RESET button ㊸ resets the counter reading to nearly "0000".
- When used in conjunction with the SEARCH switch ㊽ counter search function is available (see next chapter).

HOW TO USE THE SEARCH SWITCH



To search for a specific tape section, you can apply either the Counter Search or Cue Search mode.

Counter search

When the SEARCH switch ㊽ is set to COUNTER, the point corresponding to the counter reading of nearly "0000" is automatically located in the Fast Forward or Rewind mode. Therefore, its typical use may be: (1) press the COUNTER RESET button at the start of playback and (2) after playback, rewind the tape. Then the tape automatically stops when the counter reaches nearly "0000", facilitating the location of the tape section you want to play back again.

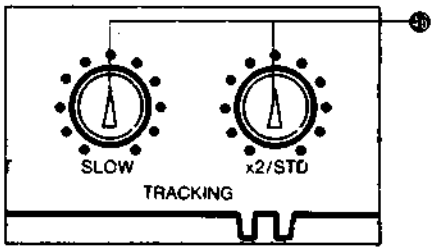
Cue search

At the beginning of every recording, a cue signal is recorded on the tape. The cue search function enables the sensing of this cue signal and stops the tape at a point where a new recording was made. Similarly to the counter search function, this mode is applicable only in the Fast Forward and Rewind modes. If you wish to view the recorded material immediately after it was made, set the SEARCH switch ㊽ to CUE. After recording, if you rewind the tape, it stops automatically where the recording was initiated (the cue signal position).

Notes

- The cue signal is recorded in the following cases:
  (1) When a recording is initiated from the Stop mode (STOP to REC).
  (2) When a timer recording is initiated (TIMER ON to REC).
  (3) When a recording is initiated from the Play mode by pressing the PLAY button together with the REC button (PLAY to REC).

HOW TO USE THE TRACKING CONTROL

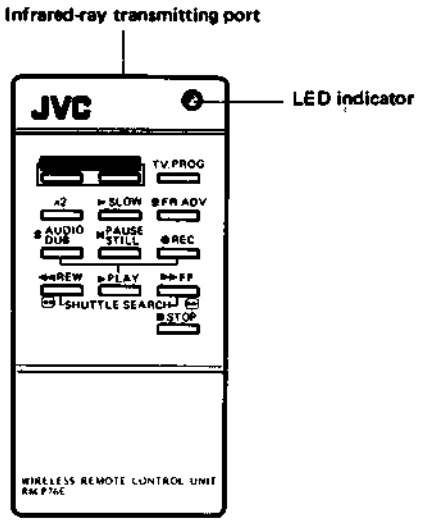


If the playback picture contains noise bars (this is likely to happen when you play back a cassette which was recorded with a different video recorder unit), adjust the TRACKING controls ㊾, X2/STD control during playback at normal and double-speed and SLOW control during slow-motion playback. Turn it slowly in either direction until the noise bars are minimized on the screen.

Note

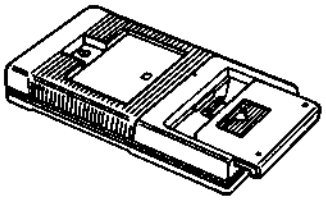
After playing back that particular cassette, be sure to return the TRACKING controls to their centre position.

HOW TO USE THE REMOTE CONTROL UNIT

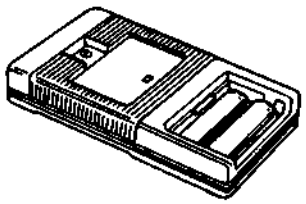


Installing the batteries

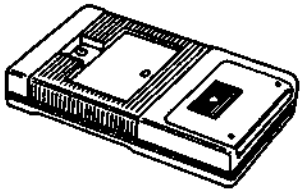
1. Slide the battery compartment cover on the rear of the unit in the direction of the arrow (►).



2. Insert 2 "R6"-size batteries (provided) in the correct directions into the battery compartment.



3. Replace the cover.



- If the LED indicator fails to light when one of the buttons is pressed after the remote control unit has been used for a long time, the battery power is insufficient. Replace all 2 batteries with fresh ones following the instructions.

Features

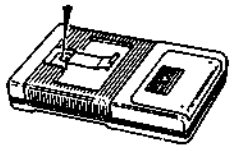
- This remote control employs infrared-ray transmission.
- Main operational buttons on the recorder are duplicated on the remote control unit for at-a-distance operation.
- This remote control can operate the recorder from a distance of up to 10 m.
- All tape control modes (except EJECT) and TV programme channel selection are possible via the remote control unit.
- There is no possibility of cross-modulation or mis-operation from other infrared remote control units.

Operation

- Direct the infrared-ray transmitting port toward the recorder's receiving window.
- The function of each button is exactly the same as that of the corresponding button on the recorder.
- For TV programme channel selection, press the TV. PROG button a number of times.
- The LED indicator on the remote control unit lights to indicate that it is transmitting a signal.
- If some channels are skipped, you don't have to press the TV. PROG button of the remote control unit a number of times to reach your desired channel.

Notes

- Do not attempt to press two buttons simultaneously (except PLAY and REC or PLAY and AUDIO DUB), otherwise malfunctioning may result.
- When you have switched the power off via the remote control unit, even though the recorder's sub-power switch is in the ON position, the recorder is inoperative (with the power indicator turned off). To re-apply power to the recorder, either press the ON button on the remote control unit or first set the recorder's sub-power switch to OFF and then set it to ON once again.
- The metal latch provided permits the remote control unit to be hooked onto various places. Attach it as illustrated.



Specifications

Power supply	: DC 3 V ("R6" battery x 2)
Dimensions	: 63 mm(W) x 130 mm(H) x 21 mm(D)
Weight	: 120 g(incl. batteries)
Operating distance	: 10 m max.

PART VI SUPPLEMENTS

ADJUST YOUR TV RECEIVER WHEN ...

Speed or Still Playback may require adjusting your TV receiver. If your TV receiver shows the following symptoms during Speed Playback or Still Playback using the HR-7600MS, adjust the TV receiver first.

Symptom	Adjustment
Picture vibrates vertically. 	Turn the V-Hold knob slightly for stabilizing.*
The upper portion of the picture drifts horizontally. 	Turn the H-Hold knob slightly for stabilizing.**
Picture rolls. 	Turn the H-Hold knob slightly for stabilizing.**
Picture is flattened vertically. 	Inherent in your TV receiver.
Only a portion of the picture continues to flicker. 	Not adjustable. Inherent in your TV receiver.

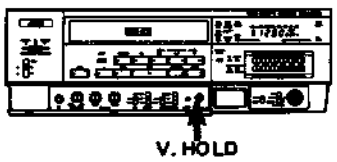
HEAD CLEANING

- Picture playback may become blurred or interrupted while the TV programme received is clear. This does not mean that the recorded programme has been erased.
- Dirt accumulated on the head after long periods of use causes such troubles. In this case, head cleaning requiring highly technical care is necessary.

*For head cleaning, consult the nearest JVC dealer.

If the V-Hold and H-Hold knobs are not provided on your TV receiver, please consult your JVC dealer.

*If an unsatisfactory result is obtained, adjust the V. HOLD knob located on the sub-control panel of the unit so that a stable picture is obtained.



** If an unsatisfactory result is obtained, it is necessary to adjust the AFC circuit of the TV receiver.

IN CASE OF DIFFICULTY

What may initially appear to be trouble is not always a real problem. Make sure first . . .

Symptoms	Check points
Clock is functioning properly, but the set is not powered with the recorder's sub-power switch set to ON.	• Have you switched the power off last via the infrared remote control unit? – If so, set the recorder's sub-power switch to OFF once and then set it to ON again. – Or simply press the remote control unit's ON button.
REC or AUDIO DUB button cannot be pressed in.	• Is the safety tab on the video cassette broken? – Reseal the slot with cellophane tape.
Buttons for variable-speed playback do not function.	• Have you pressed the PLAY button first? – If not, press it.
No colour or rolling picture.	• Is the video mode select switch (on the rear panel) set to COLOUR? • Are the SYSTEM SELECT switches set correctly? (See page 7.)
Channel cannot be changed during pretuning.	• Have you turned the tuning control while the indicator is still blinking? – If so, you cannot select any other channel. See page 16.

SPECIFICATIONS

General

Power requirement	: 110/127/220/240 V AC, 50/60 Hz
Power consumption	: 45 watts (60 W with camera)
Camera connector output	: DC 12 V ⎓ 1 A max.
Temperature	: Operating: 5°C to 40°C Storage: -20°C to 60°C
Operating position	: Horizontal only
Weight	: 12 kg
Dimensions	: 460(W) x 154(H) x 371(D) mm

Tape deck section

Format	: VHS standard
Video signal system	: PAL and SECAM colour and CCIR monochrome signal, 625 lines NTSC colour and EIA monochrome signal, 525 lines
Video recording system	: Luminance: FM recording Colour: Phase shift & converted subcarrier direct recording (PAL/NTSC) 1/4 frequency count down and direct recording (SECAM)

Aerial input	: VHF band I, channels 2 – 4 VHF band III, channels 5 – 12 UHF band IV/V, channels 21 – 69
Aerial output	: UHF channels 32 – 40 (Adjustable)

Digital clock/timer

Clock display	: 24-hour fluorescent digital display with day indication
Reference frequency	: Quartz controlled
Start time setting	: Within 2 weeks
Programming capacity	: 8 programmes
Accessories	: Aerial cable Video cassette Infrared remote control unit "R6" battery x 2 Metal latch
Optional accessory	: Wired remote control unit (RM-P73U)

Design and specifications subject to change without notice.

SECTION 1
GENERAL DESCRIPTION

[1] PAL SYSTEM

1.1 GENERAL OUTLINE

The VHS system achieves very low tape consumption and uses low cost video cassette tape. Recording time in the standard mode has become 3 hours.

Increased recording time results from the narrow gap video heads, high sensitivity video tape and the slant azimuth recording head configuration which eliminates the need for a guard band between recorded tracks.
In addition, the VHS format takes into consideration special operating modes such as still picture, slow motion and speed playback. The design also allows switching over between the SECAM and NTSC television standards.

Adoption of the VHS format presented several technical challenges. Foremost among these were obtaining high picture quality and high resolution despite the slow (4.9 meters per second) relative speed between the tape and video heads, improving signal to noise ratio (S/N), and preventing black to white reversal phenomena due to the short recording wavelength of 1.0 μm. Also the $\pm 6^{\circ}$ azimuth angle of the video heads alone is not sufficient to eliminate crosstalk from the lowband converted color signal.

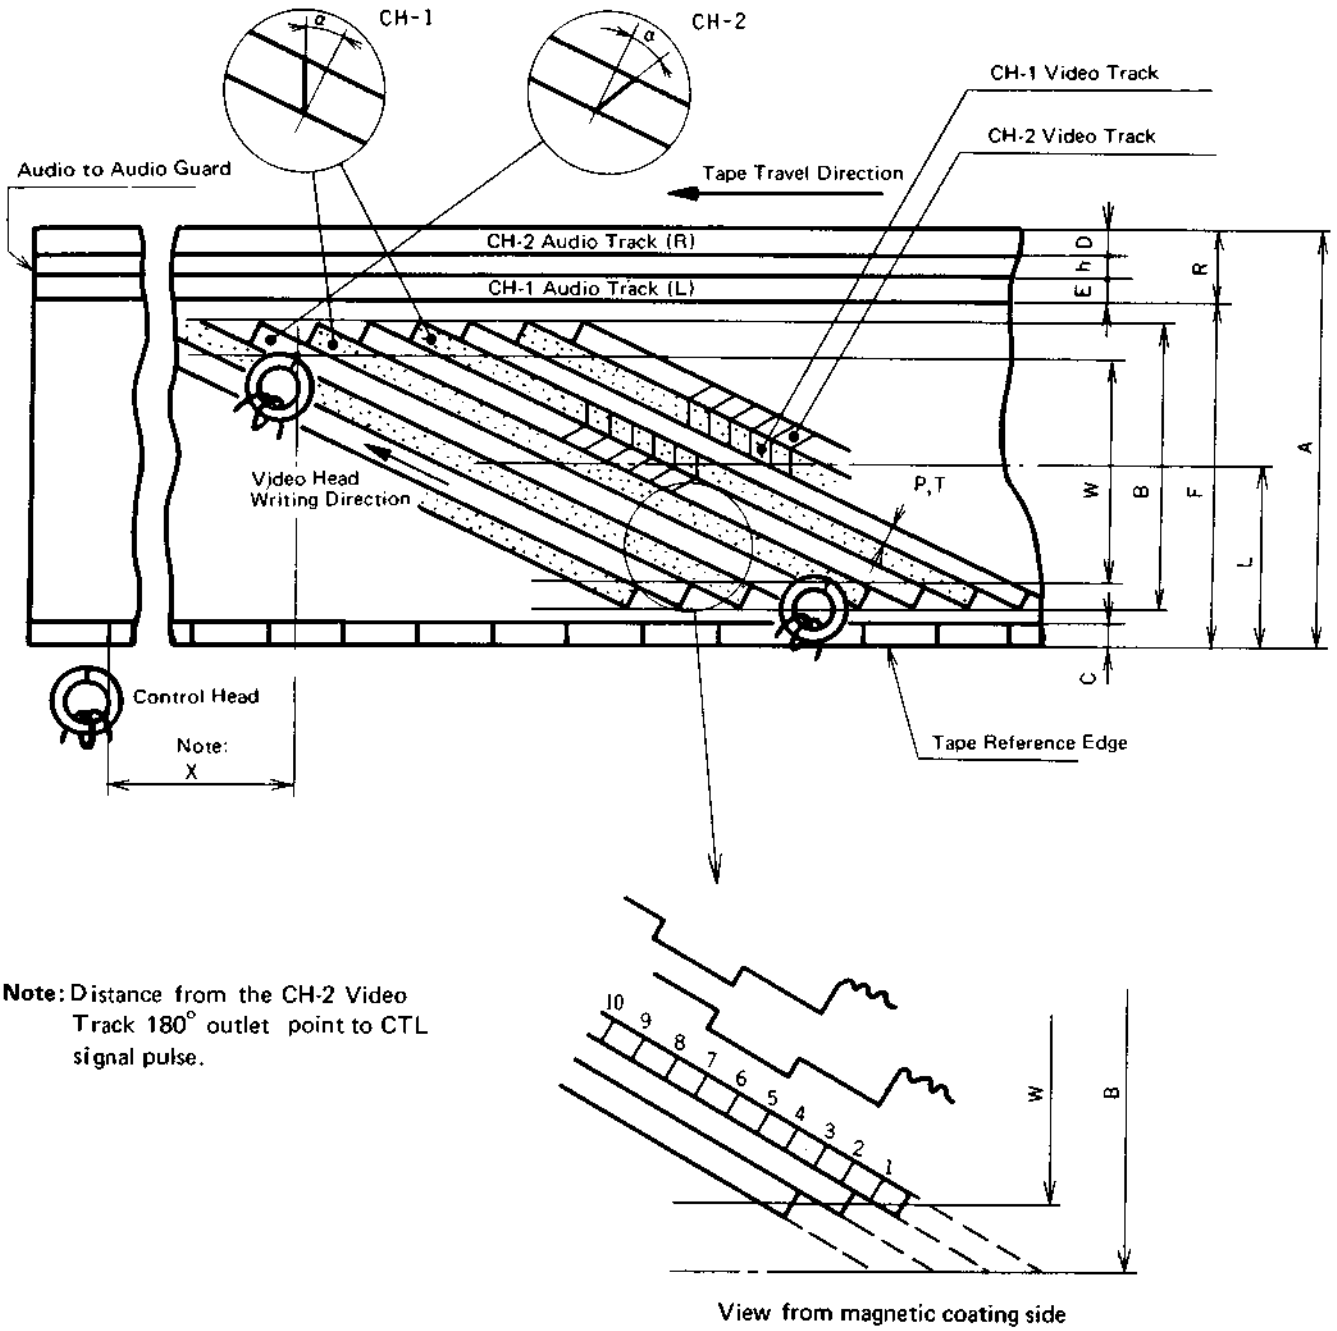
Steps for solving these difficulties included adoption of a nonlinear emphasis circuit and selecting the emphasis amount for optimum S/N. The reversal problem was overcome by using a double limiter circuit, while a phase shift system has been designed for eliminating color crosstalk.

The following discussion covers several main points of the VHS format.

1.2 MAGNETIC TAPE PATTERN

1.2.1 Standard

In the VHS format, two rotating video heads at ±6° azimuth angle are used for recording without a guard band. Fig. 1-1 indicates the recording pattern, while the pertinent values are listed in Table 1-1.



Note: Distance from the CH-2 Video Track 180° outlet point to CTL signal pulse.

Table 1-1 Magnetic tape pattern

Note: Tests and measurements shall be made under the following conditions.
Temperature: 20°C ± 2°C, Relative humidity: 65% ± 5%

1.2.2 Horizontal correlation

The azimuth head configuration removes crosstalk from most of the high frequency portion of the FM luminance signal, however, it is not able to fully eliminate crosstalk from the low frequency component of the lower sideband portion. This residual crosstalk is reduced by employing line correlation for the tape pattern.

Line correlation (or "H correlation") consists of arranging the horizontal sync signal positions of adjacent recorded tracks. Since this makes the frequencies of the main signal and crosstalk signal very close, the demodulated crosstalk amount becomes extremely low with respect to the main signal. The type of H correlation used in the VHS format is shown in Fig. 1-2

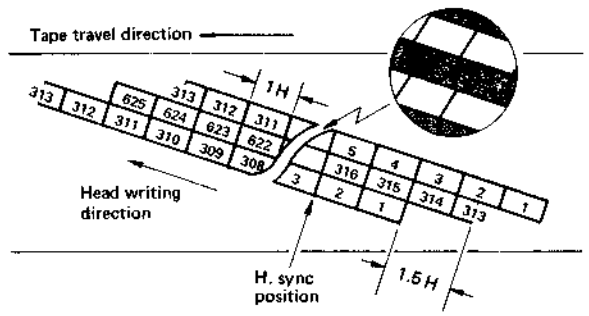

Fig. 1-2 VHS recording signal pattern

In order to provide H correlation in the tape pattern, tape speed, head drum diameter and other factors must be decided. The adjacent track correlation in the VHS format is 1.5 H. This 1.5 H difference is important not only for removing low frequency crosstalk from the luminance signal, but also for correcting color signal crosstalk in the SECAM system, for which phase shifting cannot be used.

Another advantage of H correlation is in avoiding skew distortion effects during special operating modes such as still, slow motion, 2x speed and shuttle search, when each video head traces two or more tracks. In these modes, the horizontal sync signals become played back at fixed intervals.

1.3 LUMINANCE SIGNAL RECORDING SYSTEM

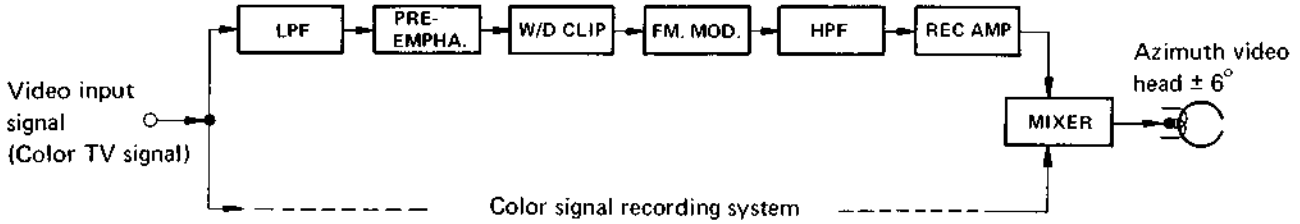

Fig. 1-3 Luminance signal recording system

Frequency modulation (FM) is used for the luminance signal recording system. A simplified block diagram of the system is shown in Fig. 1-3.

A lowpass filter (LPF) removes the color component and passes only the luminance component of the input color TV signal. At the next stage pre-emphasis circuit, the high frequency portion of the luminance signal is enhanced in order to improve S/N during FM recording. Since excess pre-emphasis could lead to black/white reversal due to the shortened recording wavelength, a white/dark clip circuit cuts the overshoot and undershoot components which exceed certain positive and negative levels.

The frequency modulator (FM MOD) converts the AM luminance signal to FM, which goes through a highpass filter (HPF) to the recording amplifier. These circuits amplify the signal with the proper frequency characteristic, after which it is mixed with the down converted color signal and supplied to the video heads.

1.3.1 Luminance signal recording frequency characteristic (LPF)

As shown in Fig. 1-4, when the video input is a color TV signal, a lowpass filter removes the color component and the luminance signal, with a bandwidth of from about 30 Hz to 3.0 MHz, is used. With some VHS models, when the input is a black and white TV signal, it bypasses the LPF, allowing a wider bandwidth to beyond 4 MHz.

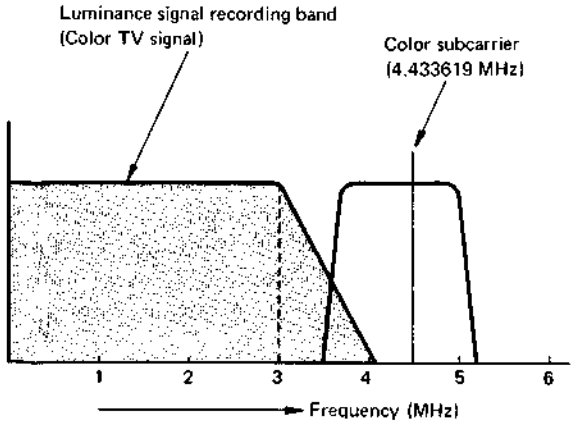

Fig. 1-4 Luminance signal recording band

1.3.2 Pre-emphasis characteristics

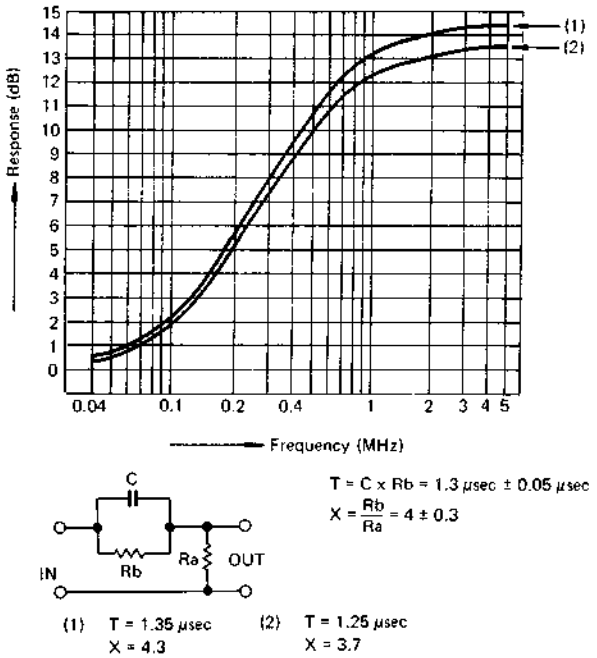

Fig. 1-5 Pre-emphasis characteristics

1.3.3 White and dark clip level (See Fig. 1-6.)

White clip level : 160^{+10}_{-50}% measured from sync tip

Dark clip level : 40 ± 10% measured from sync tip

Note: The level from sync tip to white peak is 100%.

1.3.4 FM carrier frequency and deviation (See Fig. 1-6.)

Sync tip : 3.8 ± 0.1 MHz
White peak : 4.8 ± 0.1 MHz
Deviation : 1.0 ± 0.1 MHz

1.3.5 FM signal recording frequency (HPF)

As indicated in Fig. 1-6, when the video input is a color TV signal, it goes through an HPF for vacating the area for the down converted color signal. With some VHS models, when the input is a B/W TV signal, the HPF can be bypassed to extend the bandwidth to the DC area.

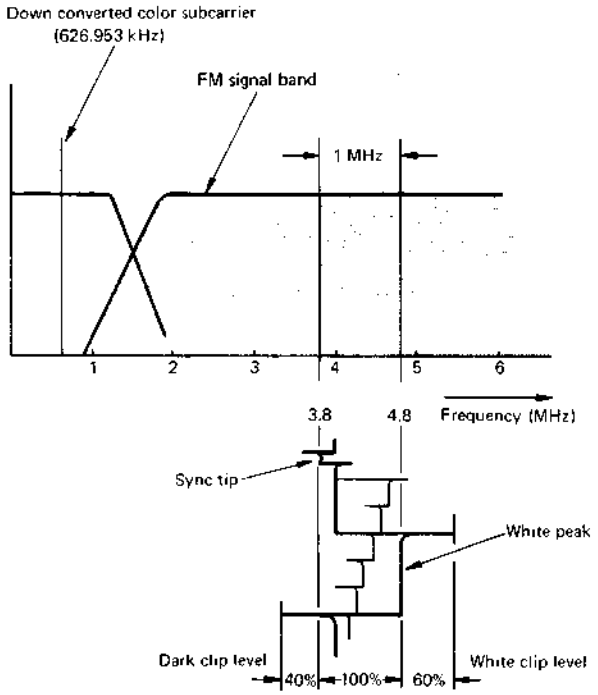

Fig. 1-6 Recording spectrum

1.3.6 FM signal recording amp. characteristics (REC AMP)

Current:

More than 3.8 MHz: Optimum saturation recording current
2 MHz : 3 ± 1 dB
1 MHz : 6 ± 1 dB
Less than 1 MHz : Flat characteristics

Note: 0 dB at 3.8 MHz

1.3.7 FM signal head current (VIDEO HEAD)

It shall be within ±1.5 dB of 4 MHz optimum recording current.

1.4 LUMINANCE SIGNAL PLAYBACK SYSTEM

This system functions to return the signals recorded on the tape to a form as close as possible to the video input signals. The simplified block diagram is shown in Fig. 1-7.

The low level FM signals played back by the two video heads are combined into a single FM signal by the switching amplifier. After amplification to the required frequency characteristic, a highpass filter attenuates the down converted color signal and passes only the FM luminance signal. This HPF has the same response as that of the recording system.

Variations in the playback FM signal level due to mechanical stretching and contraction of the tape, and irregularities in tape to head contact, are corrected by the limiter circuit. The signal is amplified more than 80 dB to permit precise demodulation. A double limiter circuit is employed in order to prevent black/white reversal effects.

In the following stages, the demodulator and lowpass filter return the luminance signal to its AM form. The de-emphasis circuit reverses the emphasis applied during recording. From this point, the signal goes to the mixer where it is mixed with the playback color signal to become the video output siganl.

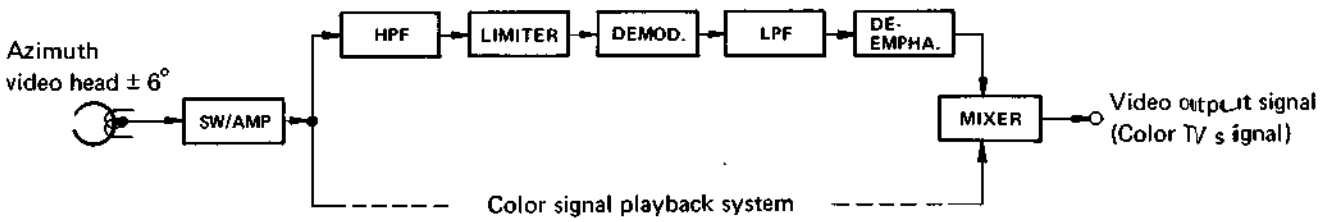

Fig. 1-7 Luminance signal playback system

1.5 COLOR SIGNAL RECORDING SYSTEM

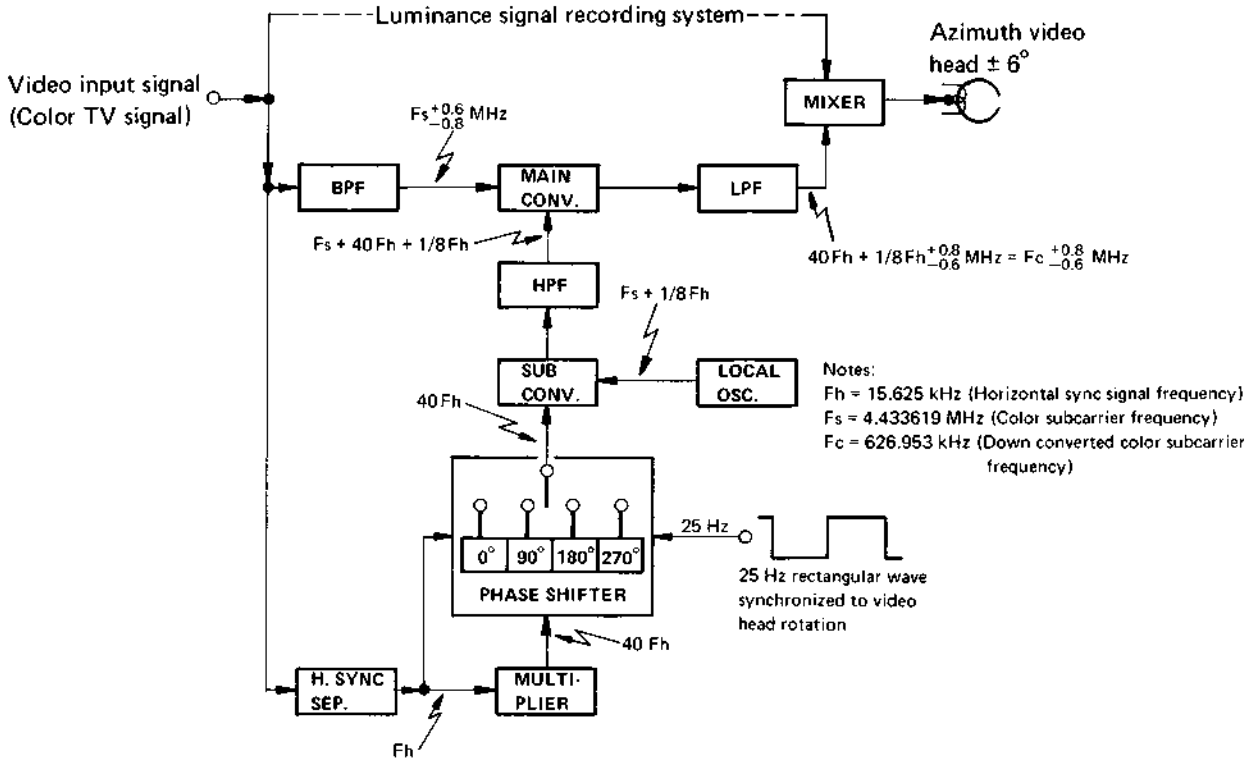

Fig. 1-8 Color signal recording system

This is a direct recording system using a down converted phase shifted color signal. The phase shift system removes color crosstalk which cannot be completely eliminated by the azimuth video heads. Fig. 1-8 illustrates a simplified block diagram of this system.

A bandpass filter (BPF) extracts the color component from the input video signal and supplies it to the main converter.

At the same time, the input signal also goes to the horizontal sync separator, which supplies the 15.625 kHz (Fh) to the multiplier and phase shift circuits. Via the phase shifter, the 40 Fh CH-1 track component is supplied directly to the sub converter, but the CH-2 component is delayed in phase 90° every line (1 H). A 25 Hz rectangular wave synchronized to the video head rotation is used for differentiating between the CH-1 and CH-2 components. Each line is also controlled by the Fh input.

The local oscillator produces the color subcarrier frequency 4.433619 MHz (Fs) + 1/8 Fh single frequency which goes to the sub converter. At the sub converter, the 40 Fh and (Fs + 1/8 Fh) are frequency converted to become (Fs + 40 Fh + 1/8 Fh). This is supplied through a highpass filter to the main converter. Also supplied to the main converter are the color signal Fs $^{+0.6}_{-0.8}$ MHz and carrier wave (Fs + 40 Fh + 1/8 Fh). These are down converted to become (40 Fh + 1/8 Fh $^{+0.8}_{-0.6}$ MHz) which through a lowpass filter goes to the mixer for mixing with the FM luminance signal. The result is applied to the video heads..

In other words, the 4.433619 MHz (Fc) color subcarrier is converted to a low band of 626.953 kHz (40 Fh + 1/8 Fh). The down converted color signal is then recorded directly using the FM luminance signal as AC bias.

1.5.1 Color crosstalk correction by phase shift system

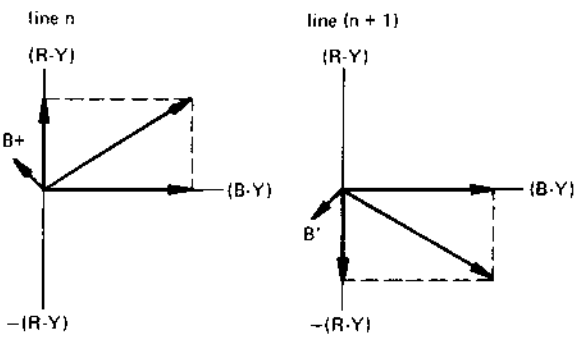

Fig. 1-9 Vector of color signal

A synchronous quadrature modulation system is employed in which the phase of the color signal R-Y component is reversed every line in order to prevent transmission distortion.

The color signal indicated in Fig. 1-9 is converted to a lowband.
While the CH-1 track component is recorded with phase unchanged, the phase of the CH-2 track component is delayed 90° every line. Fig. 1-10 illustrates the principle of this phase shift system.

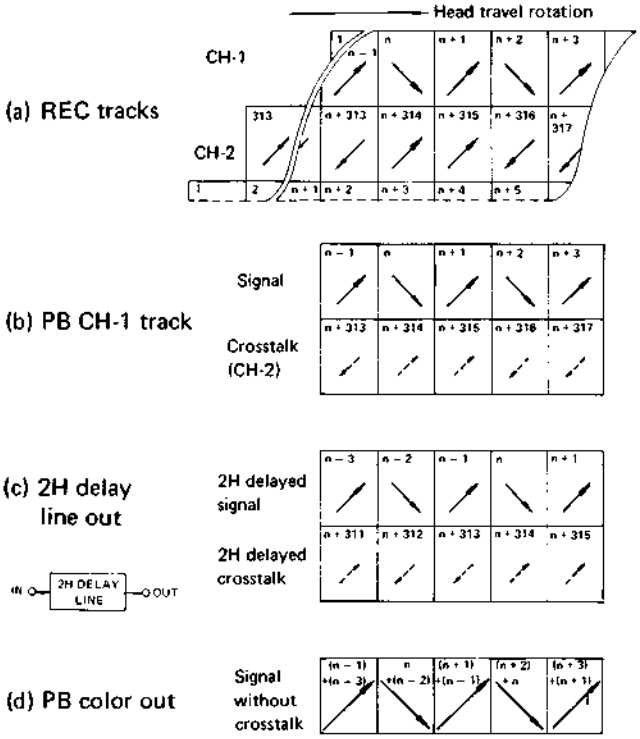

Fig. 1-10 Phase shift system

In the figure, (a) indicates the phase shifted recording pattern. Since the CH-1 head pattern is not phase shifted, the R-Y component phase becomes inverted every line. The phase of the CH-2 head pattern is delayed every line and this causes its R-Y component phase to become inverted every two lines.

During playback, when the CH-1 head picks up a portion of the CH-2 track signal, this becomes the crosstalk component. Phase shift is not required for the main signal from the CH-1 track, and this output is shown by (b). The dotted arrows indicate the crosstalk component and, as can be noted, the phase reverses every 2 lines.

Passing signal (b) through a 2H delay line yields signal (c). In comparing signals (b) and (c), the main signal phase is the same every line, but the crosstalk phase reverses. Therefore, by mixing signals (b) and (c), the crosstalk component of the adjacent track can be removed to result in the playback color signal (d).

In other words, the color signal can be considered in 2 H units. It is recorded by the phase shift system and during playback, the signal through a 2 H delay line is mixed to remove crosstalk.

Crosstalk in the playback color signal (d) effectively becomes zero, while the main signal is enhanced to improve S/N. Also, the CH-2 head playback phase is advanced 90° every line (opposite to recording), producing the same effect. A digital type system is used for phase shifting.

1.5.2 Down converted color subcarrier frequency

The color subcarrier frequency (Fs) can be expressed as:

$$Fs = (n - 1/4)\,Fh + 1/625\,Fh = 283.75\,Fh + 25\,Hz\ (n = 284) = 4.433619\,MHz$$

A line offset system is used in which the subcarrier phase is delayed 90° every line. This avoids serious color noise when the color signal is displayed on a monochrome TV receiver. 25 Hz is added in order to prevent crosscolor.

As indicated in Fig. 1-10, the phase of the color signal R-Y component is inverted every horizontal line to compose a synchronous quadrature modulated signal. Fig. 1-11 shows this color signal spectrum.

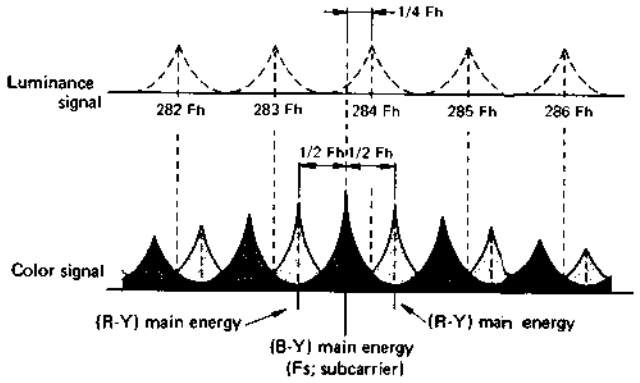

Fig. 1-11 Spectrum of color signal

In the phase shift system, the CH-1 component of the down converted color signal is distributed at 1/2 Fh intervals centered on the Fc (down converted color subcarrier) component. The CH-2 track component is delayed in phase 90° every line, deviated by 1/4 Fh, and distributed at 1/2 Fh intervals centered on Fc. This spectrum is shown in Fig. 1-12.

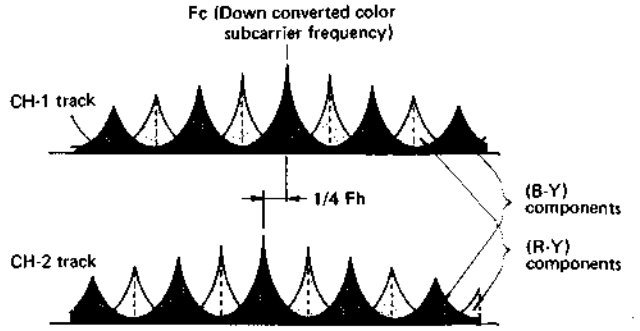

Fig. 1-12 Spectrum of down converted color signal

The FM luminance and down converted color signals are mixed to become the recording current. When recorded and played back using magnetic tape, which prossesses 3-dimensional distortion and nonlinearity, interference in the form of $F_O + 2F_{DC}$ (F_O : FM carrier; F_{DC} : down converted color signal) becomes introduced and cannot be ignored. When the $2F_{DC}$ component is detected and demodulated, beat becomes produced with respect to the luminance signal and appears in the picture. Therefore, as with the color signal, Fc (down converted color subcarrier frequency) must be selected so that the $2F_{DC}$ component becomes 1/4 offset in relation to the luminance signal, i.e.:

$$2F_C = \frac{2n-1}{4} F_H$$

$$F_C = \frac{2n-1}{8} F_H = \frac{321}{8} F_H = 40\ F_H + \frac{1}{8} F_H \quad (n = 161)$$

$$= 625 + 1.953 = 626.953\ \text{kHz}$$

When Fc is determined at (40 Fh + 1/8 Fh), the spectrum of the CH-1 track B-Y component appears at (nFh + 1/8 Fh) and the R-Y component at (nFh − 3/8 Fh). In the CH-2 track distribution, B-Y appears at (nFh − 1/8 Fh) and R-Y at (nFh − 5/8 Fh).

Fig. 1-13 shows the $2F_{DC}$ component spectrum with respect to the playback luminance signal at this time.

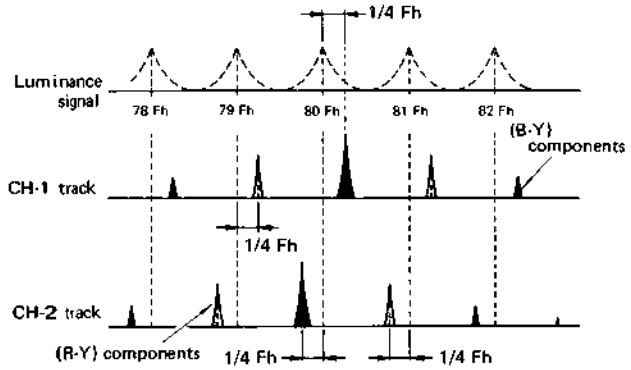

Fig. 1-13 $2F_{DC}$ playback spectrum

The $2F_{DC}$ components for both CH-1 and CH-2 become 1/4 line offset with respect to the luminance signal and thereby visually reduced. The 626.953 value was selected for both reducing noise and in consideration of color bandwidth.

1.5.3 Color signal recording bandwidth

Response curves for the highpass and lowpass filters are indicated in Fig. 1-14.

Constant current characteristics are possessed by the down converted color signal recording current.

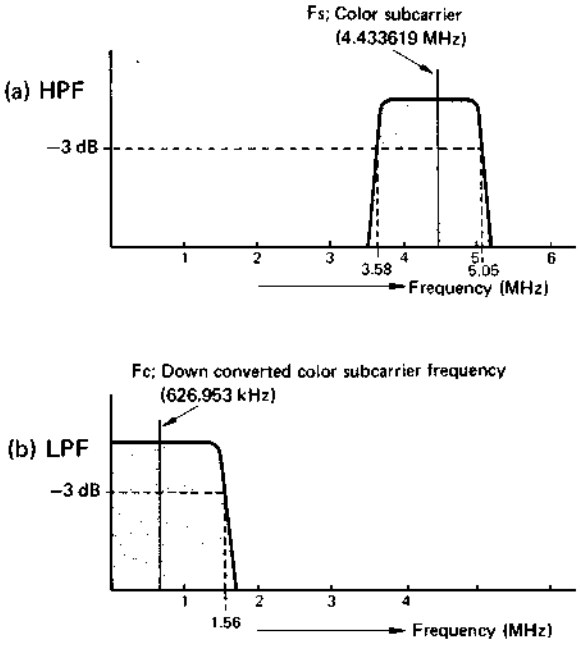

Fig. 1-14 Color signal recording bandwidth

1.6 COLOR SIGNAL PLAYBACK SYSTEM

The color signal playback system performs essentially the opposite function as the recording system. In addition, however, important corrections must be performed for color signal frequency and phase errors introduced by variations in tape speed and head rotation, and elasticity of the tape.
Fig. 1-15 indicates an abbreviated block diagram of this system.

Though a lowpass filter, the down converted color signal goes to the main converter. At this time, the down converted color subcarrier (Fc) contains an error component (40 Fh' + 1/8 Fh' ± Δf) due to mechanical factors of the heads and tape. Fh' varies with the tape speed as Fh ± ΔFh. Δf is the instantaneous error caused by head rotation irregularities and tape elongation and contraction.

The 40 Fh' frequency deviation component is compensated by supplying the video output signal to the horizontal sync separator, multiplier and phase shifter, and 40 Fh' to the sub converter. This forms the AFC (automatic frequency compensator) loop.

In the APC (automatic phase compensator) loop, the 1/8 F'h ± Δf phase error component is compensated by comparing the burst component of the up converted playback color signal with the subcarrier frequency from the local oscillator and APC detector. A variable crystal oscillator (VXO) produces (Fs + 1/8Fh' ± Δf) which goes to the sub converter. As a result, (Fs + 40 Fh' + 1/8 Fh' + Δf) is supplied as the main converter carrier input from the sub converter through a highpass filter.

By frequency conversion with Fc, the color subcarrier frequency of 4.433619 MHz, which is free from frequency and phase deviations, becomes obtained through a bandpass filter. In the opposite manner as with recording, the phase shifter advances the CH-2 track phase 90° every line and 40 Fh' is supplied to the sub converter. The playback color signal through the main converter and bandpass filter is applied to a 2 H delay line for removing crosstalk. Characteristics of the lowpass and bandpass filters are the same as those for recording (Fig. 1-15).

At the mixer, the playback color and luminance signals are mixed to become the video output signal.

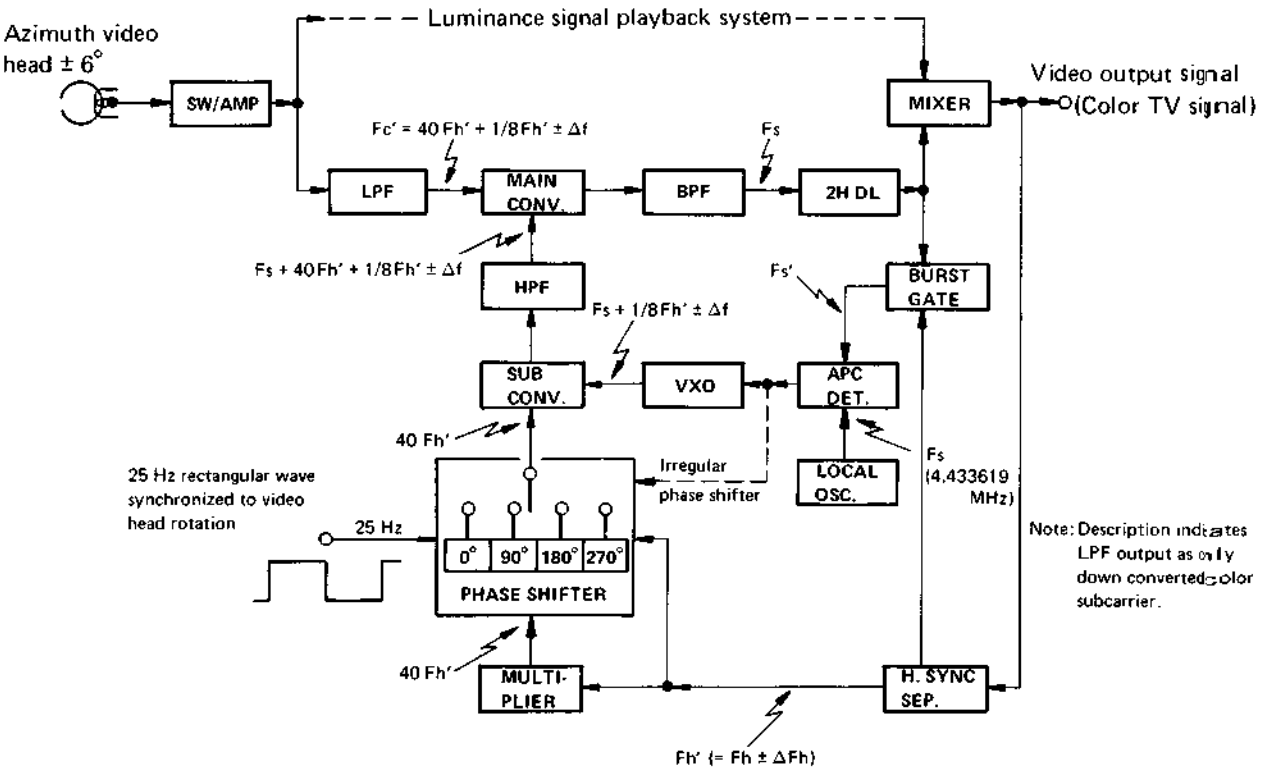

Fig. 1-15 Color signal playback system

1.7 CONTROL SIGNAL RECORDING SYSTEM

Control signal waveform, polarity and video head relationships are indicated in Fig. 1-16.

Phase of the control signal is the same as the vertical sync signal rise component of the CH-1 track. The positive pulse voltage is the reference 25 Hz.

The control signal is recorded on the control track above the saturation recording level.

1.9 CASSETTE

1.9.1 Video tape

Length : The relationship between tape length and time for recording and playback can be defined by the formula:

$$L = [1.42t + 2]^{+3}_{0}$$

where, L : tape length (m)
t : recording or playback time (minutes)

Note: L shall be an integer obtained after all decimals produced in calculation are raised. (See "Reference Table".)

Width : 12.65 ± 0.01 mm
Fluctuation : less than 6 μm
Thickness : 19^{+1}_{-2} μm
Coercivity : 600 oersted class (nominal)
Optimum recording current shall not differ from the standard tape.

[Reference Table]

Kinds of blank cassettes

Kind of cassette	Recording or playback time	Length of video tape
E-180	180 min.	258^{+3}_{0} m
E-150	150 min.	215^{+3}_{0} m
E-120	120 min.	173^{+3}_{0} m
E-90	90 min.	130^{+3}_{0} m
E-60	60 min.	88^{+3}_{0} m
E-30	30 min.	45^{+3}_{0} m

1.9.2 Leader tape and Trailer tape

Length : In case time for recording or playback is:
over 90 minutes : 170 ± 20 mm
just or under 90 minutes : 150 ± 20 mm
Width : 12.65 ± 0.03 mm
Thickness : 40^{+5}_{-25} μm
Material : Polyester film
Transparency : more than 50%
Length of splicing: 12 ~ 19 mm
Gap of splicing : 0 ~ 70 μm
Splicing force : more than 3 kg

1.9.3 Reel

Outside diameter : 89 ± 0.2 mm
Hub diameter : In case time for recording or playback is:
over 90 minutes : 26 ± 0.15 mm
just or under 90 minutes : 62 ± 0.2 mm
(If just or under 30 minutes, it can be 70 ± 0.2 mm.)
E-value : more than 1.5 mm

[2] SECAM SYSTEM

1.1 GENERAL OUTLINE

The VHS system achieves very low tape consumption and uses low cost video cassette tape. Recording time in the standard mode has become 3 hours.

Increased recording time results from the narrow gap video heads, high sensitivity video tape and the slant azimuth recording head configuration which eliminates the need for a guard band between recorded tracks.
In addition, the VHS format takes into consideration special operating modes such as still picture, slow motion and speed playback. The design also allows switching over between the PAL and NTSC television standards.

Adoption of the VHS format presented several technical challenges. Foremost among these were obtaining high picture quality and high resolution despite the slow (4.9 meters per second) relative speed between the tape and video heads, improving signal to noise ratio (S/N), and preventing black to white reversal phenomena due to the short recording wavelength of 1.0 μm. Also the $\pm 6^{\circ}$ azimuth angle of the video heads alone is not sufficient to eliminate crosstalk from the lowband converted color FM signal.

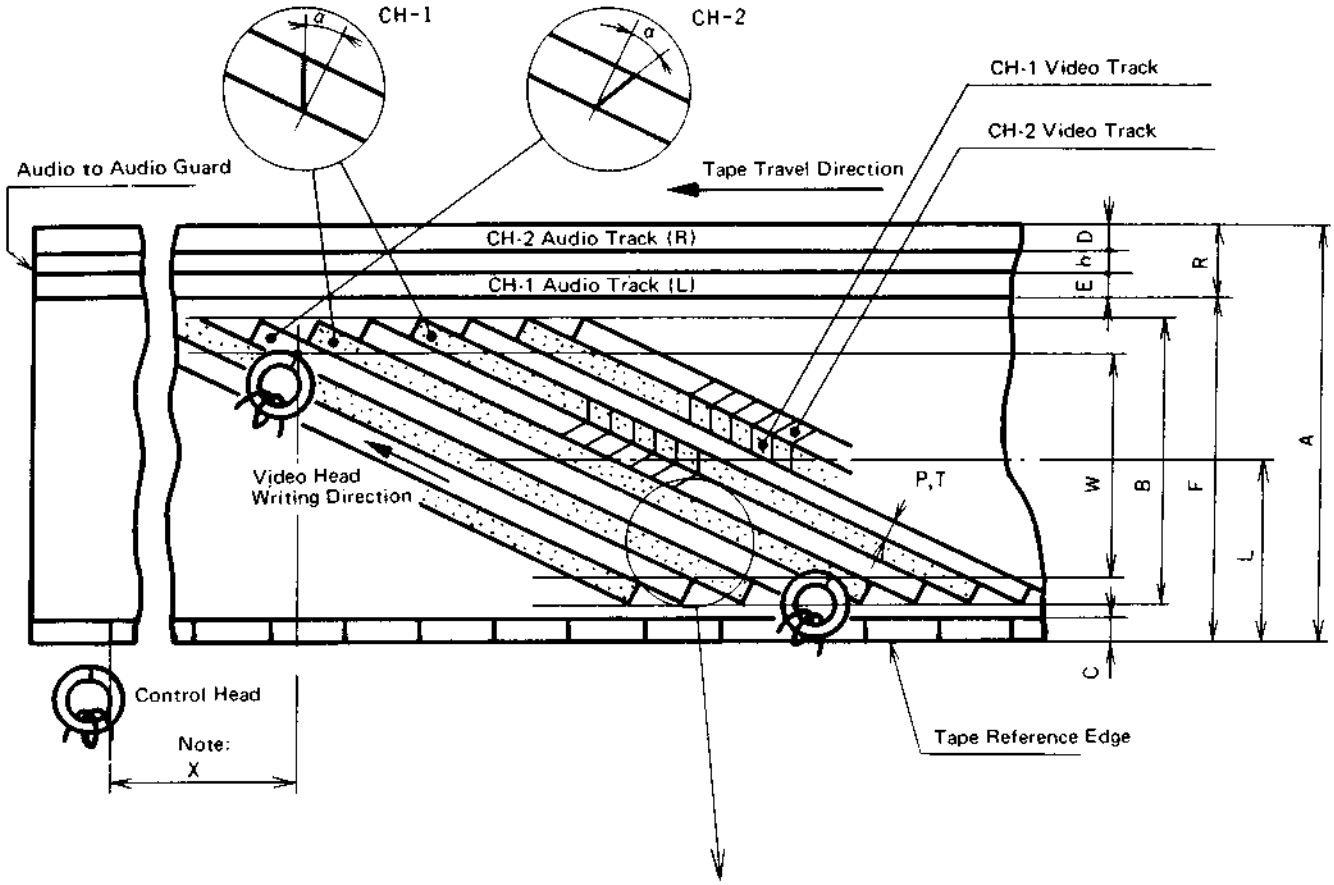
Steps for solving these difficulties included adoption of a nonlinear emphasis circuit and selecting the emphasis amount for optimum S/N. The reversal problem was overcome by using a double limiter circuit, while a 1/4 frequency count down system and a line correlation for the tape pattern have been designed for eliminating color crosstalk.

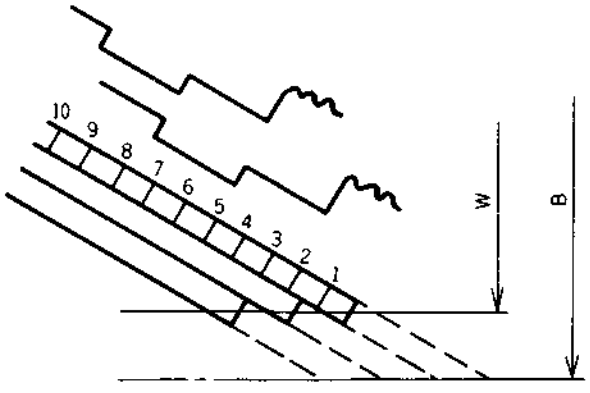
The following discussion covers several main points of the VHS format.

1.2 MAGNETIC TAPE PATTERN

1.2.1 Standard

In the VHS format, two rotating video heads at ±6° azimuth angle are used for recording without a guard band. Fig. 1-20 indicates the recording pattern, while the pertinent values are listed in Table 1-2.





View from magnetic coating side

Note: Distance from the CH-2 Video Track 180° outlet point to CTL signal pulse.

Fig. 1-20 Magnetic tape pattern

Table 1-2 Magnetic tape pattern

Note: Tests and measurements shall be made under the following conditions.
Temperature: 20°C ± 2°C, Relative humidity: 65% ± 5%
However, unless essential to the judgement, these can also be done under the following conditions.
Temperature: 5 ~ 35°C, Relative humidity: 40 ~ 80%

1.2.2 Horizontal correlation

The azimuth head configuration removes crosstalk from most of the high frequency portion of the FM luminance signal, however, it is not able to fully eliminate crosstalk from the low frequency component of the lower sideband portion. This residual crosstalk is reduced by employing line correlation for the tape pattern.

Line correlation (or "H correlation") consists of arranging the horizontal sync signal positions of adjacent recorded tracks. Since this makes the frequencies of the main signal and crosstalk signal very close, the demodulated crosstalk amount becomes extremely low with respect to the main signal. The type of H correlation used in the VHS format is shown in **Fig. 1-21**.

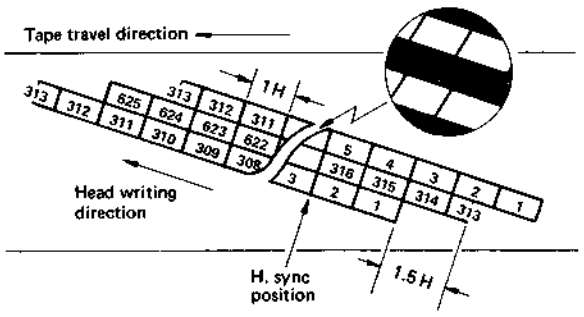

Fig. 1-21 VHS recording signal pattern

In order to provide H correlation in the tape pattern, tape speed, head drum diameter and other factors must be decided. The adjacent track correlation in the VHS format is 1.5 H. This 1.5 H difference is important not only for removing low frequency crosstalk from the luminance signal, but also for correcting color FM signal crosstalk in the SECAM system.

Another advantage of H correlation is in avoiding skew distortion effects during special operating modes such as still, slow motion, 2x speed and shuttle search, when each video head traces two or more tracks. In these modes, the horizontal sync signals become played back at fixed intervals.

1.3 LUMINANCE SIGNAL RECORDING SYSTEM

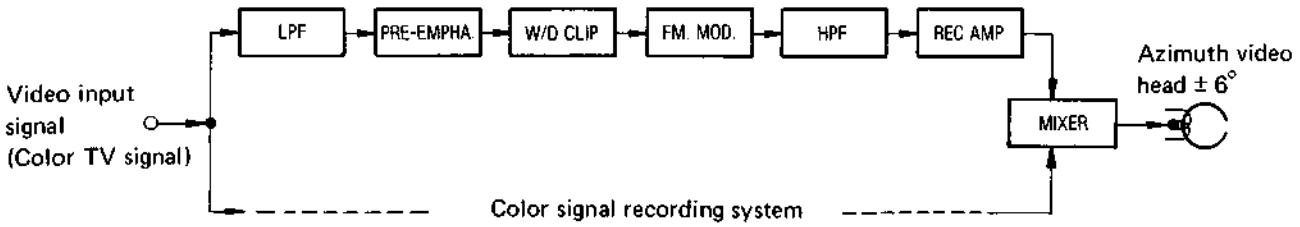

Fig. 1-22 Luminance signal recording system

Frequency modulation (FM) is used for the luminance signal recording system. A simplified block diagram of the system is shown in Fig. 1-22.

A lowpass filter (LPF) removes the color component and passes only the luminance component of the input color TV signal. At the next stage pre-emphasis circuit, the high frequency portion of the luminance signal is enhanced in order to improve S/N during FM recording. Since excess pre-emphasis could lead to black/white reversal due to the shortened recording wavelength, a white/dark clip circuit cuts the overshoot and undershoot components which exceed certain positive and negative levels.

The frequency modulator (FM MOD) converts the AM luminance signal to FM, which goes through a highpass filter (HPF) to the recording amplifier. These circuits amplify the signal with the proper frequency characteristic, after which it is mixed with the down converted color signal and supplied to the video heads.

1.3.1 Luminance signal recording frequency characteristic (LPF)

As shown in Fig. 1-23, when the video input is a color TV signal, a lowpass filter removes the color component and the luminance signal, with a bandwidth of from about 30 Hz to 3.0 MHz, is used. With some VHS models, when the input is a black and white TV signal, it bypasses the LPF, allowing a wider bandwidth to beyond 4 MHz.

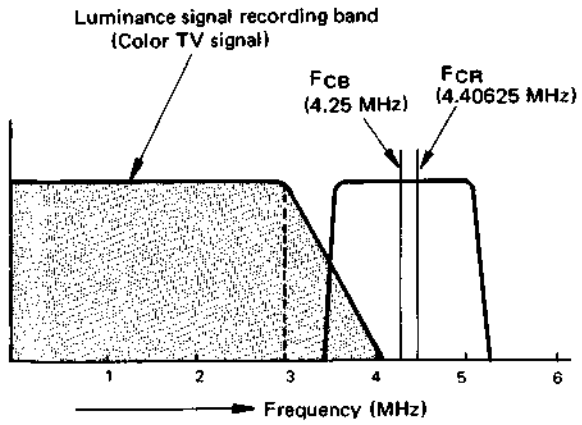

Fig. 1-23 Luminance signal recording band

1.3.2 Pre-emphasis characteristics

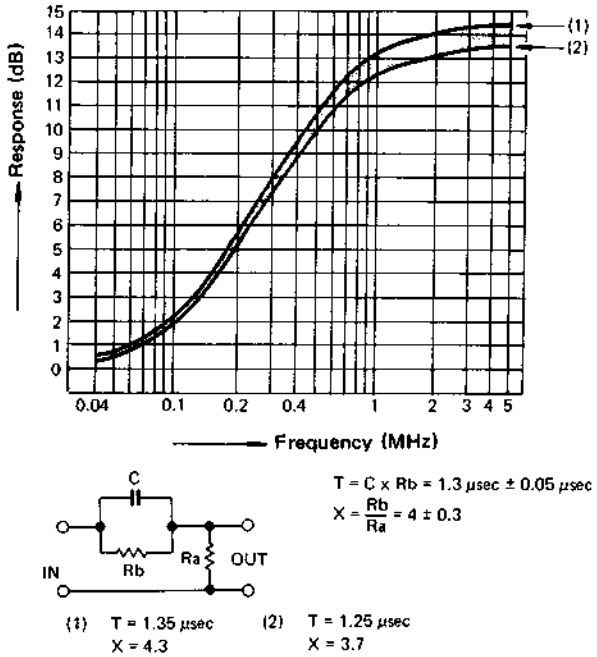

Fig. 1-24 Pre-emphasis characteristics

1.3.3 White and dark clip level (See Fig. 1-25.)

White clip level : 160^{+10}_{-50}% measured from sync tip

Dark clip level : 40 ± 10% measured from sync tip

Note: The level from sync tip to white peak is 100%.

1.3.4 FM carrier frequency and deviation (See Fig. 1-25.)

Sync tip : 3.8 ± 0.1 MHz
White peak : 4.8 ± 0.1 MHz
Deviation : 1.0 ± 0.1 MHz

1.3.5 FM signal recording frequency (HPF)

As indicated in Fig. 1-25, when the video input is a color TV signal, it goes through an HPF for vacating the area for the down converted color signal. With some VHS models, when the input is a B/W TV signal, the HPF can be bypassed to extend the bandwidth to the DC area.

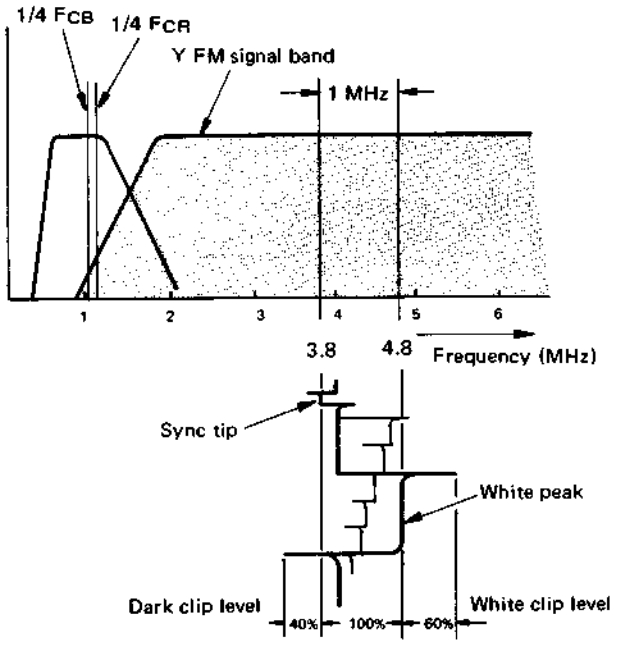

Fig. 1-25 Recording spectrum

1.3.6 FM signal recording amp. characteristics (REC AMP)

Current:

More than 3.8 MHz: Optimum saturation recording current
2 MHz : 3 ± 1 dB
1 MHz : 6 ± 1 dB
Less than 1 MHz : Flat characteristics

Note: 0 dB at 3.8 MHz

1.3.7 FM signal head current (VIDEO HEAD)

It shall be within ±1.5 dB of 4 MHz optimum recording current.

1.4 LUMINANCE SIGNAL PLAYBACK SYSTEM

This system functions to return the signals recorded on the tape to a form as close as possible to the video input signals. The simplified block diagram is shown in Fig. 1-26.

The low level FM signals played back by the two video heads are combined into a single FM signal by the switching amplifier. After amplification to the required frequency characteristic, a highpass filter attenuates the down converted color signal and passes only the FM luminance signal. This HPF has the same response as that of the recording system.

Variations in the playback FM signal level due to mechanical stretching and contraction of the tape, and irregularities in tape to head contact, are corrected by the limiter circuit. The signal is amplified more than 80 dB to permit precise demodulation. A double limiter circuit is employed in order to prevent black/white reversal effects.

In the following stages, the demodulator and lowpass filter return the luminance signal to its AM form. The de-emphasis circuit reverses the emphasis applied during recording. From this point, the signal goes to the mixer where it is mixed with the playback color signal to become the video output siganl.

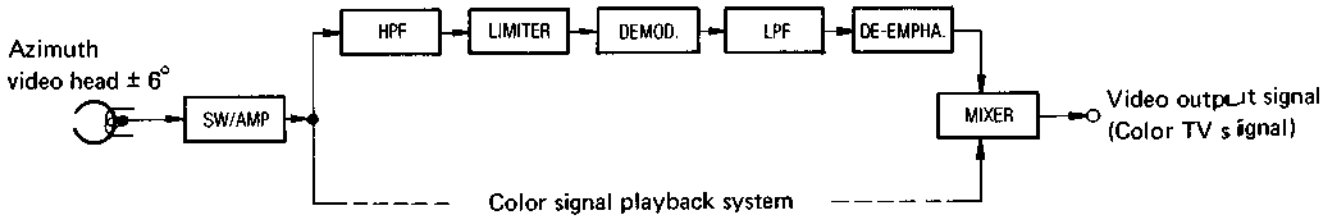

Fig. 1-26 Luminance signal playback system

1.5 COLOR SIGNAL RECORDING SYSTEM

1.5.1 SECAM color television signal

The SECAM color signal is frequency modulated in order to avoid color hue fluctuations due to phase distortion in the transmitting system. Alternating lines are used for the modulated R-Y and B-Y signals. Two subcarrier frequencies are employed: 282 Fh = 4.40625 MHz (Fh = 15.625 kHz) for the R-Y component and 272 Fh = 4.25000 MHz for the B-Y component, which reduce the visible appearance of dot interference between the scanning lines.

To provide compatibility with B/W television, the signal goes through an anti-bell filter with a center frequency of 4.286 MHz. This attenuates the unmodulated carrier component, after which the signal is mixed with luminance.

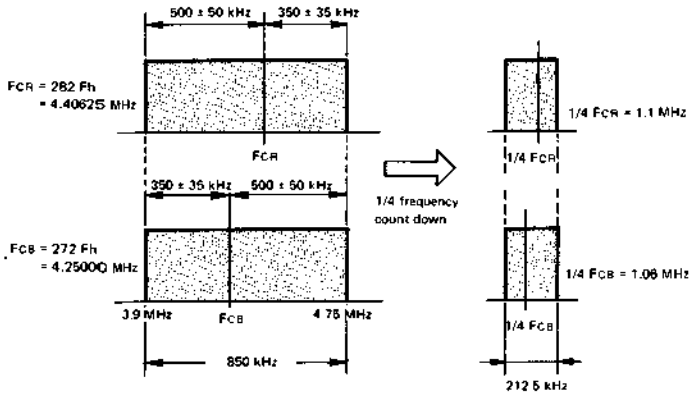
Since pre-emphasis is applied prior to modulation, the frequency deviation range of the color FM carrier becomes 850 kHz between 3.9 MHz and 4.75 MHz. When the sidebands are included, the resulting range exceeds 2 MHz.

Because of the wider color signal bandwidth of SECAM, the down converted phase shift system used for PAL and NTSC cannot be applied effectively due to the difference in azimuth effect between the high and low frequency components of the down converted color signal.

The line sequential FM signal also does not include phase correlation between lines, which makes crosstalk removal by the rotation method difficult. As a result of these factors, a 1/4 countdown direct recording system is used for SECAM.

1.5.2 1/4 frequency countdown recording

1. Color FM carrier bandwidth



(a) Color FM carrier bandwidth (b) 1/4 frequency counted down color FM carrier bandwidth

Fig. 1-27 Color FM carrier bandwidth

Fig. 1-27 (a) indicates the FM carrier bandwidth of the color signal, while (b) shows the counted down bandwidth. By counting down the frequency 1/4th, the recording bandwidth becomes 1/4th and azimuth loss difference between high and low frequency components can be reduced.

2. Color signal horizontal correlation

The color FM signal pattern based on the horizontal correlation of section 1.2.2 is shown in Fig. 1-28.

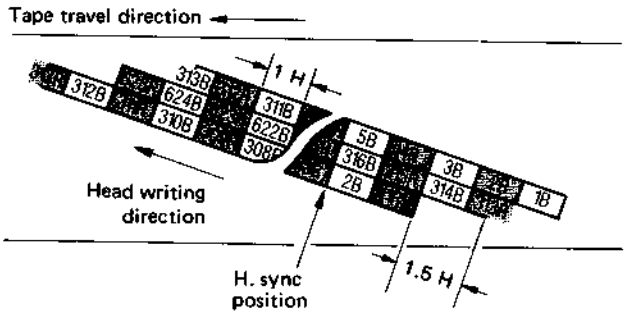


Fig. 1-28 Recording color signal pattern

As indicated, the pattern is distributed with a 1.5 H difference between adjacent tracks. The horizontal sync signals of adjacent tracks are arranged, while the R-Y and B-Y components become distributed between the adjacent track sync periods.

Consequently, in the same manner as the luminance signal, the color FM signal also possesses line and field correlations. The angular frequency difference between the playback main and crosstalk signals becomes nearly zero, while the demodulated crosstalk amount is very small compared to the main signal.

In this manner, the SECAM signal can be recorded in the VHS type format without using a guardband and without a crosstalk preventing circuit.

3. Modulation index

The color signal FM carrier covers the 850 kHz frequency range from 3.9 to 4.75 MHz, and when the FM waveform sidebands are included, the occupied range becomes more than 2 MHz. Since the sidebands remain unchanged even after 1/4th frequency countdown, they continue to cover the 2 MHz range centered on 1/4 FCR and 1/4 FCB.

However, after frequency countdown, the modulation index becomes 1/4th. Therefore, the sideband level is reduced about 10 dB with respect to the carrier component, which increases the margin for avoiding color reversal effects.

With a 1/4th modulation index, the required bandwidth for the color signal can be reduced to about 1/4th, thereby reducing the recording bandwidth by several hundred kHz. As a result, both sidebands of the color FM signal are recorded, reducing the likelihood of color reversal.

1.5.3 Recording block diagram

A simplified block diagram of the 1/4 frequency countdown direct recording system is shown in Fig. 1-29.

Bandpass filter BPF-1 separates the color component from the input video signal. The bell block functions to return the signal from the anti-bell characteristic used during transmission to a flat waveform which is easily counted down. The signal then goes through a limiter to the 1/4 frequency countdown circuit.

This circuit converts the color FM carrier from the 3.9 to 4.75 MHz range to the 0.98 to 1.19 MHz range. The next stage BPF-2 then limits the upper range of the frequency prior to mixing with the FM luminance signal.

In consideration of S/N and color reversal, the lower sideband is limited, after which the signal goes to the lowband anti-bell block. This circuit imparts an anti-bell characteristic to the counted down FM carrier. The unmodulated carrier component is attenuated and S/N improved.

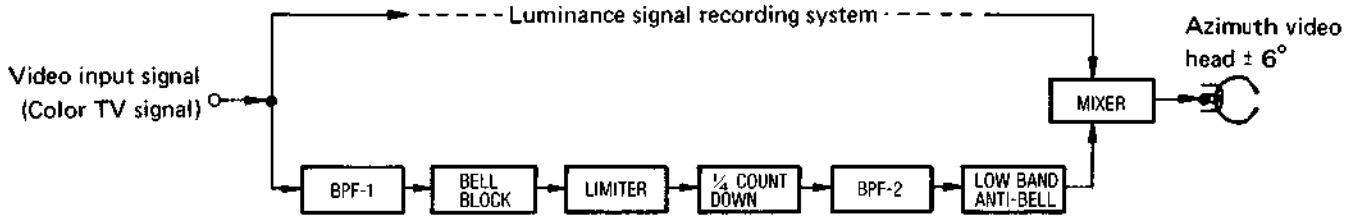

Fig. 1-29 Color signal recording system

1.5.4 Recording bandwidth

Fig. 1-30 illustrates the response curves of BPF-1 and BPF-2.

A constant current characteristic is used for recording the counted down color signal.

The generalized characteristics of the bell and lowband anti-bell blocks for recording are shown in Fig. 1-31.

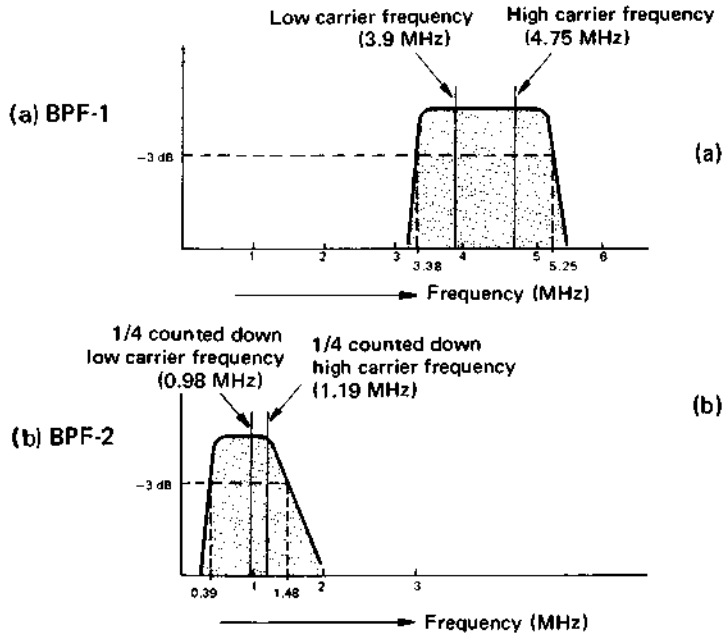

Fig. 1-30 Color signal recording bandwidth

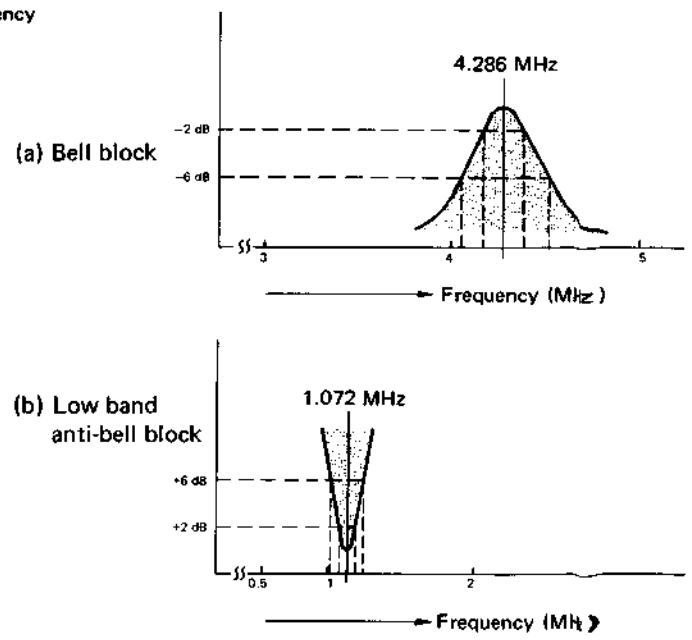

Fig. 1-31 Recording bell block characteristic

1.6 COLOR SIGNAL PLAYBACK SYSTEM

This system functions in the opposite manner as the recording system. In the case of NTSC and PAL, compensating loop circuits are needed to correct for frequency and phase variations in the playback color signal due to fluctuations in tape speed, head rotation and tape elasticity, which can cause color shifts or loss of color in the TV receiver display. However, since the SECAM signal is FM, frequency and phase deviations do not pose a problem. The compensating circuits are therefore not needed. The simplified block diagram is shown in Fig 1-32.

The lowband color FM signal is obtained by applying the playback signal to a lowpass filter. After shaping by the lowband bell block, the 4 times countup circuit returns the wide bandwidth of the color FM signal.

A bandpass filter yields the specified color signal bandwidth, after which the anti-bell block attenuates the unmodulated carrier component. The signal is then mixed with luminance to produce the video output signal.

Characteristics of the bandpass filter are the same as those of BPF-1 indicated in Fig. 1-30, while the bell block characteristics are opposite of those shown in Fig. 1-31.

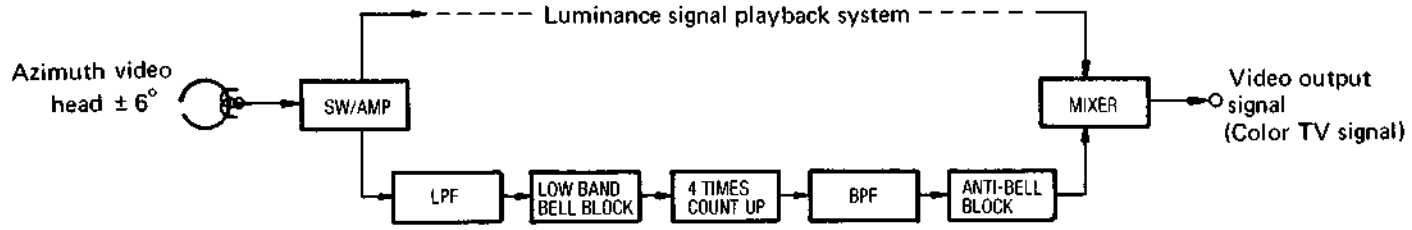

Fig. 1-32 Color signal playback system

1.7 CONTROL SIGNAL RECORDING SYSTEM

Control signal waveform, polarity and video head relationships are indicated in Fig. 1-33.

Phase of the control signal is the same as the vertical sync signal rise component of the CH-1 track. The positive pulse voltage is the reference 25 Hz.

The control signal is recorded on the control track above the saturation recording level.

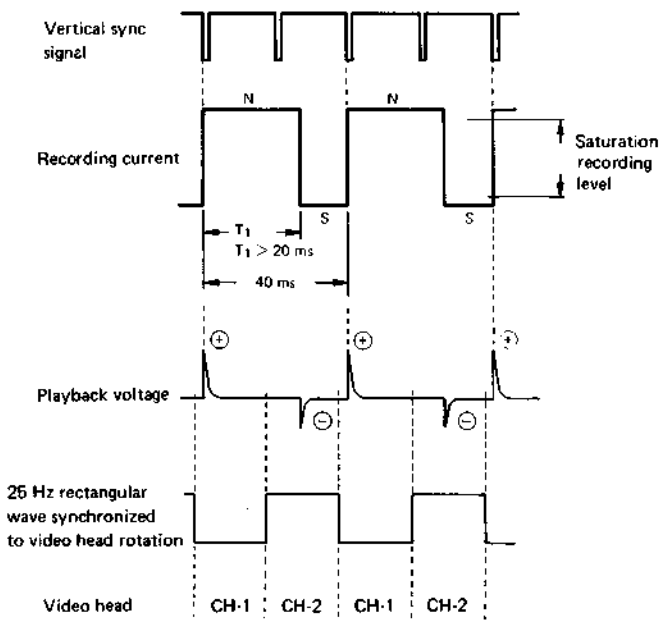

Fig. 1-33 Control signal

1.8 AUDIO SIGNAL RECORDING SYSTEM

Audio signal is recorded on the audio track to the defined level using an AC bias current recording system.

1.8.2 Audio signal recording current characteristics

The equalizing amplifier controls the recording current in order to obtain a flat frequency characteristic in the reproduced output. See Fig. 1-34.

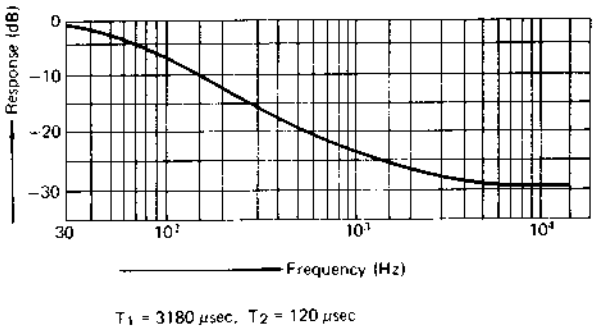

Fig. 1-34 Audio equalizing frequency characteristics

1.9 CASSETTE

1.9.1 Video tape

Length : The relationship between tape length and time for recording and playback can be defined by the formula:

$$L = [1.42t + 2]^{+3}_{0}$$

where, L : tape length (m)
t : recording or playback time (minutes)

Note: L shall be an integer obtained after all decimals produced in calculation are raised. (See "Reference Table".)

Width : 12.65 ± 0.01 mm
Fluctuation : less than 6 μm
Thickness : $19^{+}_{-}\frac{1}{2}$ μm
Coercivity : 600 oersted class (nominal)
Optimum recording current shall not differ from the standard tape.

[Reference Table]

Kinds of blank cassettes

Kind of cassette	Recording or playback time	Length of video tape
E-180	180 min.	258^{+3}_{0} m
E-150	150 min.	215^{+3}_{0} m
E-120	120 min.	173^{+3}_{0} m
E-90	90 min.	130^{+3}_{0} m
E-60	60 min.	88^{+3}_{0} m
E-30	30 min.	45^{+3}_{0} m

1.9.2 Leader tape and Trailer tape

Length : In case time for recording or playback is:
over 90 minutes : 170 ± 20 mm
just or under 90 minutes : 150 ± 20 mm
Width : 12.65 ± 0.03 mm
Thickness : 40^{+5}_{-25} μm
Material : Polyester film
Transparency : more than 50%
Length of splicing: 12 ~ 19 mm
Gap of splicing : 0 ~ 70 μm
Splicing force : more than 3 kg

1.9.3 Reel

Outside diameter : 89 ± 0.2 mm
Hub diameter : In case time for recording or playback is:
over 90 minutes : 26 ± 0.15 mm
just or under
90 minutes : 62 ± 0.2 mm
(If just or under 30 minutes, it can be 70 ± 0.2 mm.)
E-value : more than 1.5 mm

[3] NTSC SYSTEM

1.1 GENERAL OUTLINE

The VHS system achieves very low tape consumption and uses low cost video cassette tape. Recording time in the standard mode has become 2 hours.

Increased recording time results from the narrow gap video heads, high sensitivity video tape and the slant azimuth recording head configuration which eliminates the need for a guard band between recorded tracks.
In addition, the VHS format takes into consideration special operating modes such as still picture, slow motion and speed playback.

Adoption of the VHS format presented several technical challenges. Foremost among these were obtaining high picture quality and high resolution despite the slow (5.9 meters per second) relative speed between the tape and video heads, improving signal to noise ratio (S/N), and preventing black to white reversal phenomena due to the short recording wavelength of 1.2 μm. Also the $\pm 6^{\circ}$ azimuth angle of the video heads alone is not sufficient to eliminate crosstalk from the lowband converted color signal.

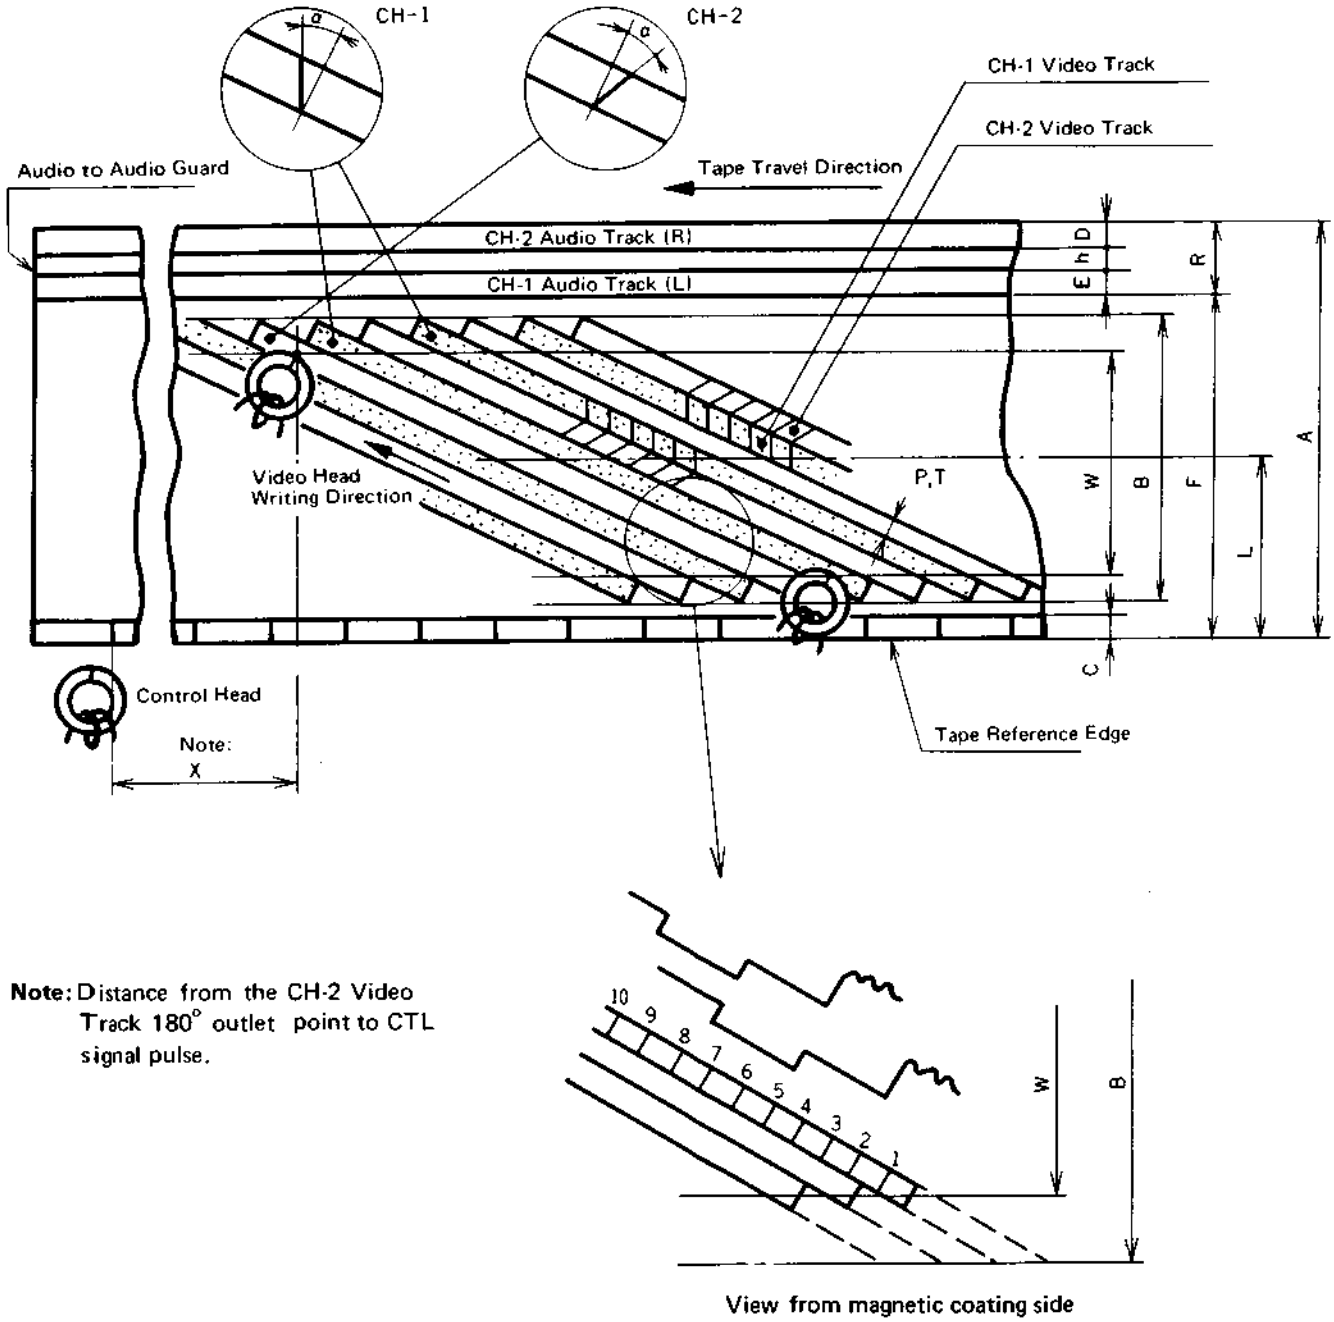
Steps for solving these difficulties included adoption of a nonlinear emphasis circuit and selecting the emphasis amount for optimum S/N. The reversal problem was overcome by using a double limiter circuit, while a phase shift system has been designed for eliminating color crosstalk.

The following discussion covers several main points of the VHS format.

1.2 MAGNETIC TAPE PATTERN

1.2.1 Standard

In the VHS format, two rotating video heads at ±6° azimuth angle are used for recording without a guard band. Fig. 1-37 indicates the recording pattern, while the pertinent values are listed in Table 1-3.



View from magnetic coating side

Note: Distance from the CH-2 Video Track 180° outlet point to CTL signal pulse.

Table 1-3 Magnetic tape pattern

Note: Tests and measurements shall be made under the following conditions.
Temperature: 20°C ± 2°C, Relative humidity: 65% ± 5%
However, unless essential to the judgement, these can also be done under the following conditions.
Temperature: 5 ~ 35°C, Relative humidity: 40 ~ 80%

1.2.2 Horizontal correlation

The azimuth head configuration removes crosstalk from most of the high frequency portion of the FM luminance signal, however, it is not able to fully eliminate crosstalk from the low frequency component of the lower sideband portion. This residual crosstalk is reduced by employing line correlation for the tape pattern.

Line correlation (or "H correlation") consists of arranging the horizontal sync signal positions of adjacent recorded tracks. Since this makes the frequencies of the main signal and crosstalk signal very close, the demodulated crosstalk amount becomes extremely low with respect to the main signal. The type of H correlation used in the VHS format is shown in Fig. 1-38.

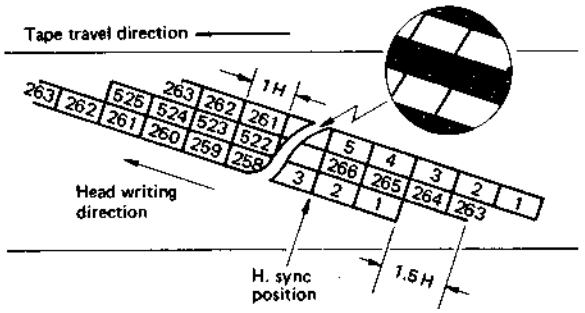

Fig. 1-38 VHS recording signal pattern

In order to provide H correlation in the tape pattern, tape speed, head drum diameter and other factors must be decided. The adjacent track correlation in the VHS format is 1.5 H. This 1.5 H difference is important for removing low frequency crosstalk from the luminance signal.

Another advantage of H correlation is in avoiding skew distortion effects during special operating modes such as still, slow motion, 2x speed and shuttle search, when each video head traces two or more tracks. In these modes, the horizontal sync signals become played back at fixed intervals.

Note: The recording pattern of 6-hour extended mode satisfies the horizontal correlation.

1.3 LUMINANCE SIGNAL RECORDING SYSTEM

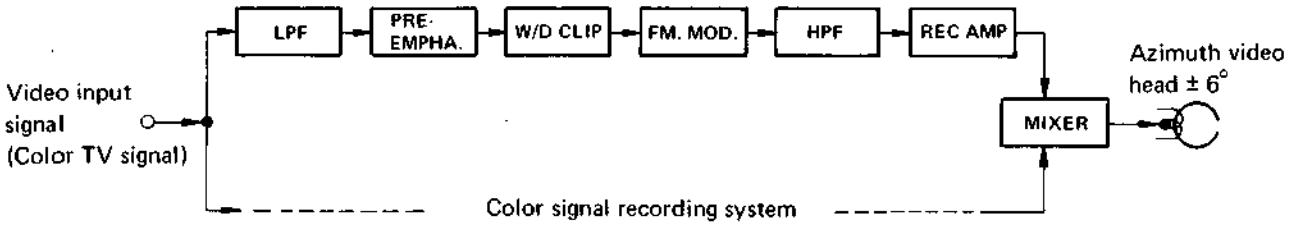

Fig. 1-39 Luminance signal recording system

Frequency modulation (FM) is used for the luminance signal recording system. A simplified block diagram of the system is shown in Fig. 1-39.

A lowpass filter (LPF) removes the color component and passes only the luminance component of the input color TV signal. At the next stage pre-emphasis circuit, the high frequency portion of the luminance signal is enhanced in order to improve S/N during FM recording. Since excess pre-emphasis could lead to black/white reversal due to the shortened recording wavelength, a white/dark clip circuit cuts the overshoot and undershoot components which exceed certain positive and negative levels.

The frequency modulator (FM MOD) converts the AM luminance signal to FM, which goes through a highpass filter (HPF) to the recording amplifier. These circuits amplify the signal with the proper frequency characteristic, after which it is mixed with the down converted color signal and supplied to the video heads.

1.3.1 Luminance signal recording frequency characteristic (LPF)

As shown in Fig. 1-40, when the video input is a color TV signal, a lowpass filter removes the color component and the luminance signal, with a bandwidth of from about 30 Hz to 3.0 MHz, is used. With some VHS models, when the input is a black and white TV signal, it bypasses the LPF, allowing a wider bandwidth to beyond 4.2 MHz.

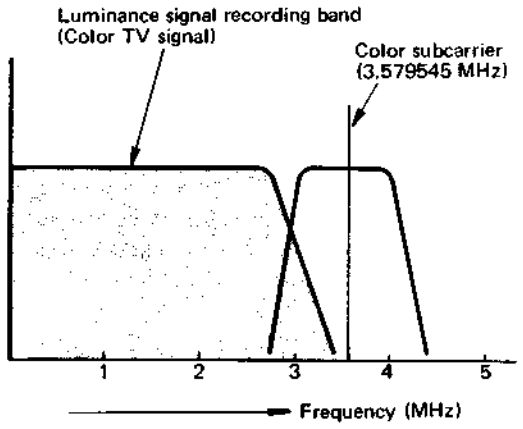

Fig. 1-40 Luminance signal recording band

1.3.2 Pre-emphasis characteristics

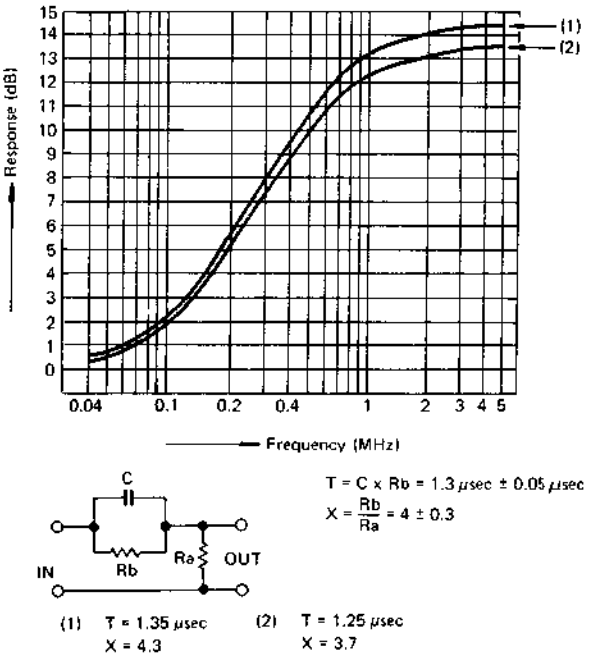

Fig. 1-41 Pre-emphasis characteristics

1.3.3 White and dark clip level (See Fig. 1-42.)

White clip level : 160^{+10}_{-5}% measured from sync tip

Dark clip level : 40 ± 10% measured from sync tip

Note: The level from sync tip to white peak is 100%.

1.3.4 FM carrier frequency and deviation (See Fig. 1-42.)

Sync tip : 3.4 ± 0.1 MHz
White peak : 4.4 ± 0.1 MHz
Deviation : 1.0 ± 0.1 MHz

1.3.5 FM signal recording frequency (HPF)

As indicated in Fig. 1-42, when the video input is a color TV signal, it goes through an HPF for vacating the area for the down converted color signal. With some VHS models, when the input is a B/W TV signal, the HPF can be bypassed to extend the bandwidth to the DC area.

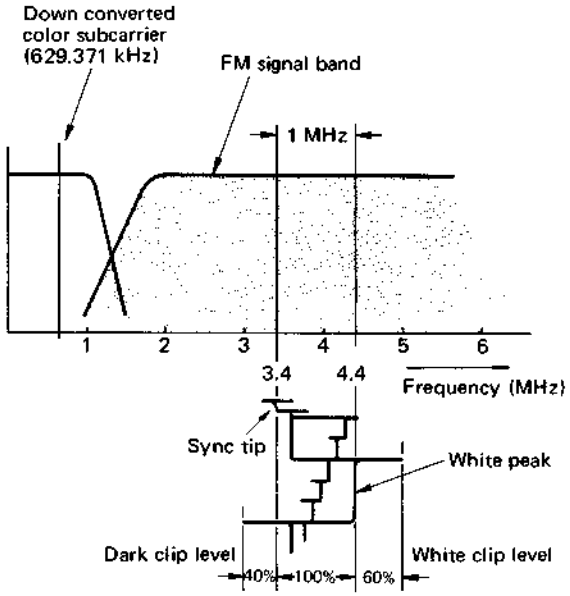

Fig. 1-42 Recording spectrum

1.3.6 FM signal recording amp. characteristics (REC AMP)

Current:

More than 3.8 MHz: Optimum saturation recording current
2 MHz : 3 ± 1 dB
1 MHz : 6 ± 1 dB
Less than 1 MHz : Flat characteristics

Note: 0 dB at 3.8 MHz

1.3.7 FM signal head current (VIDEO HEAD)

Specified to be within ±1.5 dB of 4 MHz optimum recording current.

1.4 LUMINANCE SIGNAL PLAYBACK SYSTEM

This system functions to return the signals recorded on the tape to a form as close as possible to the video input signals. The simplified block diagram is shown in Fig. 1-43.

The low level FM signals played back by the two video heads are combined into a single FM signal by the switching amplifier. After amplification to the required frequency characteristic, a highpass filter attenuates the down converted color signal and passes only the FM luminance signal. This HPF has the same response as that of the recording system.

Variations in the playback FM signal level due to mechanical stretching and contraction of the tape, and irregularities in tape to head contact, are corrected by the limiter circuit. The signal is amplified more than 80 dB to permit precise demodulation. A double limiter circuit is employed in order to prevent black/white reversal effects.

In the following stages, the demodulator and lowpass filter return the luminance signal to its AM form. The de-emphasis circuit reverses the emphasis applied during recording. From this point, the signal goes to the mixer where it is mixed with the playback color signal to become the video output signal.

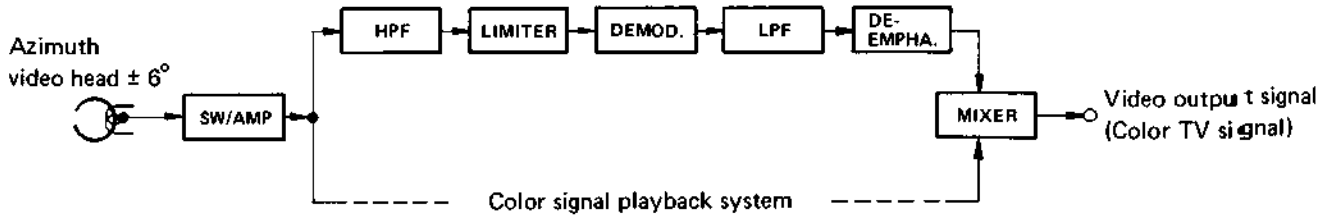

Fig. 1-43 Luminance signal playback system

1.5 COLOR SIGNAL RECORDING SYSTEM

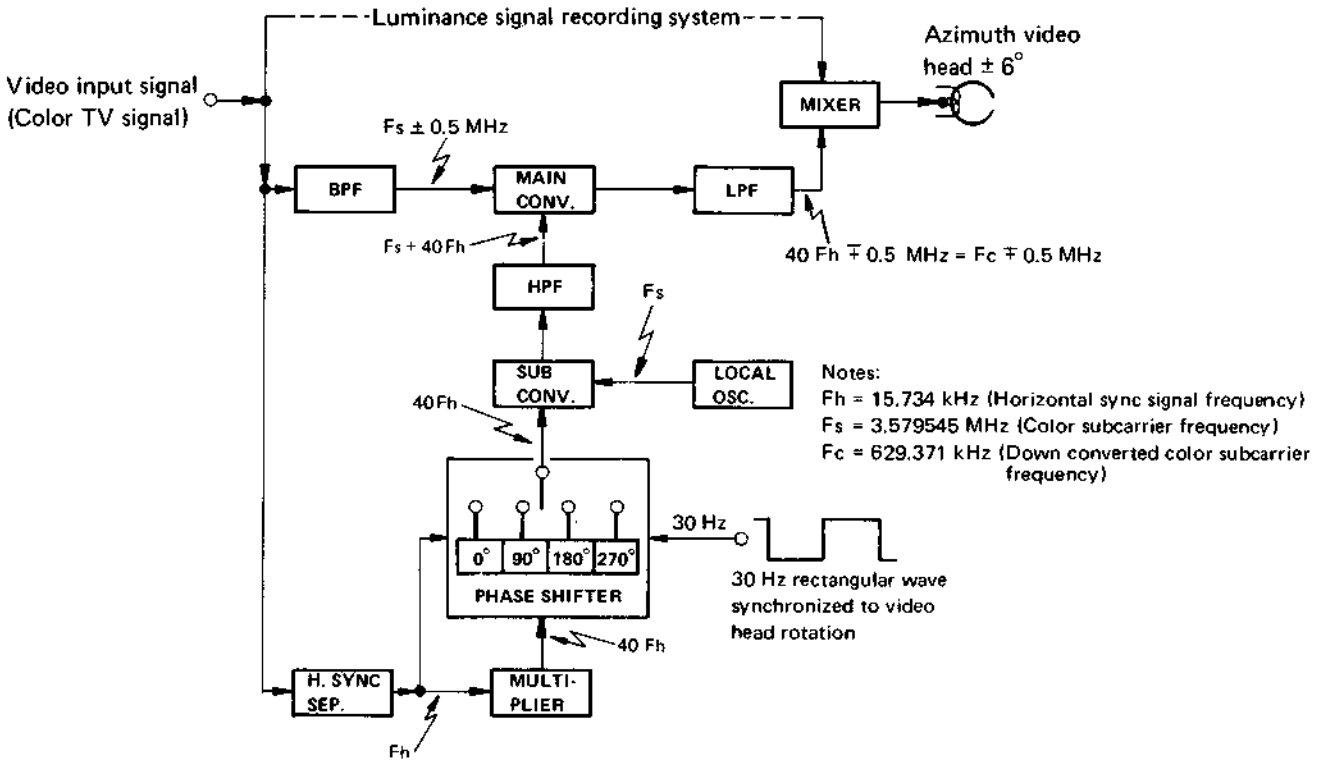

Fig. 1-44 Color signal recording system

This is a direct recording system using a down converted phase shifted color signal. The phase shift system removes color crosstalk which cannot be completely eliminated by the azimuth video heads. Fig. 1-44 illustrates a simplified block diagram of this system.

A bandpass filter (BPF) extracts the color component from the input video signal and supplies it to the main converter.

At the same time, the input signal also goes to the horizontal sync separator, which supplies the 15.734 kHz (Fh) to the multiplier and phase shift circuits. Via the phase shifter, the 40 Fh CH-1 track component is advanced in phase each line (1 H) and supplied to the sub converter, while the CH-2 component is delayed in phase 90° every line (1 H). A 30 Hz rectangular wave synchronized to the video head rotation is used for differentiating between the CH-1 and CH-2 components. Each line is also controlled by the Fh input.

The local oscillator produces the color subcarrier frequency 3.579545 MHz (Fs). At the sub converter, the goes to the sub converter. At the sub converter, the 40 Fh and Fs are frequency converted to become (Fs + 40 Fh). This is supplied through a highpass filter to the main converter. Also supplied to the main converter are the color signal Fs ± 0.5 MHz and carrier wave (Fs + 40 Fh). These are down converted to become (40 Fh ∓ 0.5 MHz) which through a lowpass filter goes to the mixer for mixing with the FM luminance signal. The result is applied to the video heads.

In other words, the 3.579545 MHz (Fc) color subcarrier is converted to a low band of 629.371 kHz (40 Fh). The down converted color signal is then recorded directly using the FM luminance signal as AC bias.

1.5.1 Color crosstalk correction by phase shift system

While the CH-1 track component is advanced 90° every line and recorded, the phase of the CH-2 track component is dilayed 90° every line. Fig. 1-45 illustrates the principle of this phase shift system.

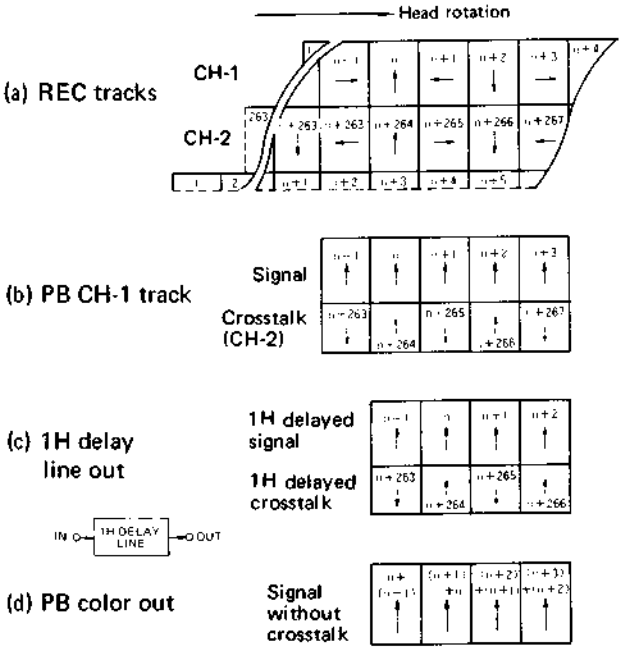

Fig. 1-45 Phase shift system

In the figure, (a) indicates the phase shifted recording pattern. The CH-1 head pattern phase is advanced 90° every line. The phase of the CH-2 head pattern is delayed every line.

During playback, when the CH-1 head picks up a portion of the CH-2 track signal, this becomes the crosstalk component. The main signal is delayed 90° every line from the CH-1 track, and this output is shown by (b). The dotted arrows indicate the crosstalk component and, as can be noted, the phase reverses every line.

Passing signal (b) through a 1 H delay line yields signal (c). In comparing signals (b) and (c), the main signal phase is the same every line, but the crosstalk phase reverses. Therefore, by mixing signals (b) and (c), the crosstalk component of the adjacent track can be removed to result in the playback color signal (d).

In other words, the signal is recorded by the phase shift system and during playback, it is mixed with the signal through a 1 H delay line to remove crosstalk.

Crosstalk in the playback color signal (d) effectively becomes zero, while the main signal is enhanced to improve S/N. Also, the CH-2 head playback phase is advanced 90° every line (opposite to recording), producing the same effect. A digital type system is used for phase shifting.

1.5.2 Down converted color subcarrier frequency

The color subcarrier frequency (Fs) can be expressed as:

Fs = 1/2Fh x n (n = odd number: 455)
= 3.579545 MHz

A frequency interleaving system (line offset system) is used. This avoids serious color noise when the color signal is displayed on a monochrome TV receiver.
Fig. 1-46 shows this color signal spectrum.

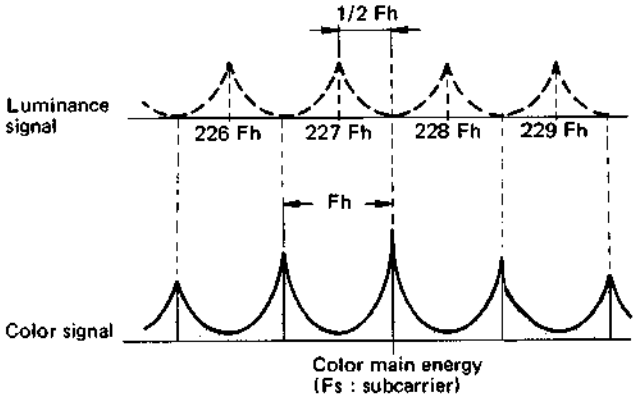

Fig. 1-46 Spectrum of colorsignal

In the phase shift system, the CH-1 component of the down converted color signal is advanced in phase 90° every line, deviated by plus 1/4 Fh, and distributed at 1/2 Fh intervals centered on the Fc (down converted color subcarrier) component. The CH-2 track component is delayed in phase 90° every line, deviated by minus 1/4 Fh, and distributed at 1/2 Fh interval centered on Fc. This spectrum is shown in Fig. 1-47.

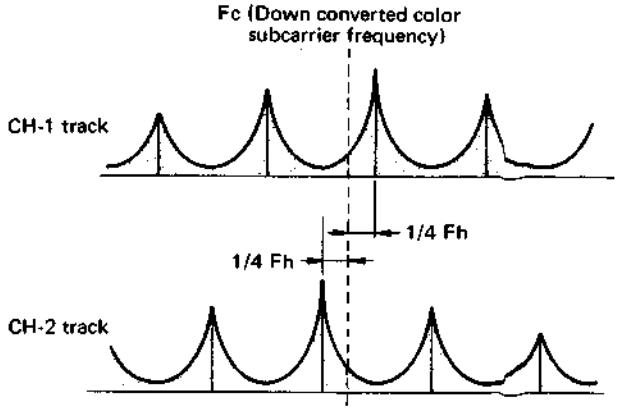

Fig. 1-47 Spectrum of down converted color signal

The FM luminance and down converted color signals are mixed to become the recording current. When recorded and played back using magnetic tape, which prossesses 3-dimensional distortion and nonlinearity, interference in the form of Fo + 2FDC (Fo : FM carrier; FDC : down converted color signal) becomes introduced and cannot be ignored. When the 2FDC component is detected and demodulated, beat becomes produced with respect to the luminance signal and appears in the picture. Therefore, as with the color signal, Fc (down converted color subcarrier frequency) must be selected so that the frequency of the 2FDC component becomes interleaved (1/2 offset) in relation to the luminance signal.

When Fc is determined at 40 Fh, the 2 FDC spectrum of the CH-1 track component appears at (+1/2 Fh) and in the CH-2 track distribution, the 2 FDC spectrum appears at (nFh – Fh).

Fig. 1-48 shows the 2 FDC component spectrum with respect to the playback luminance signal at this time.

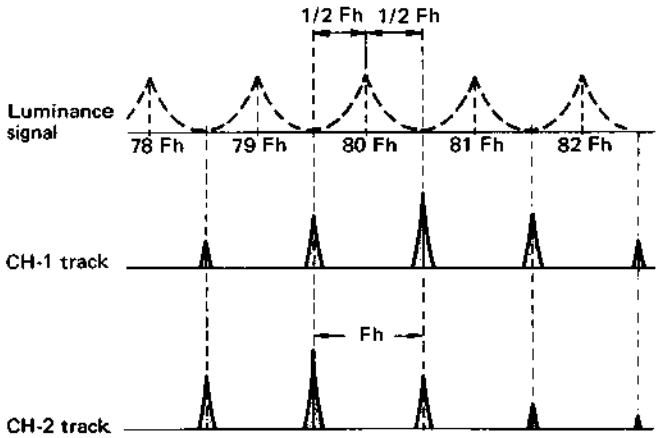

Fig. 1-48 2 FDC playback spectrum

The 2 FDC components for both CH-1 and CH-2 become interleaved (1/2 line offset) with respect to the luminance signal and thereby visually reduced. The 629.371 value was selected for both reducing noise and in consideration of color bandwidth.

1.5.3 Color signal recording bandwidth

Response curves for the bandpass and lowpass filters are indicated in Fig. 1-49.

Constant current characteristics are possessed by the down converted color signal recording current.

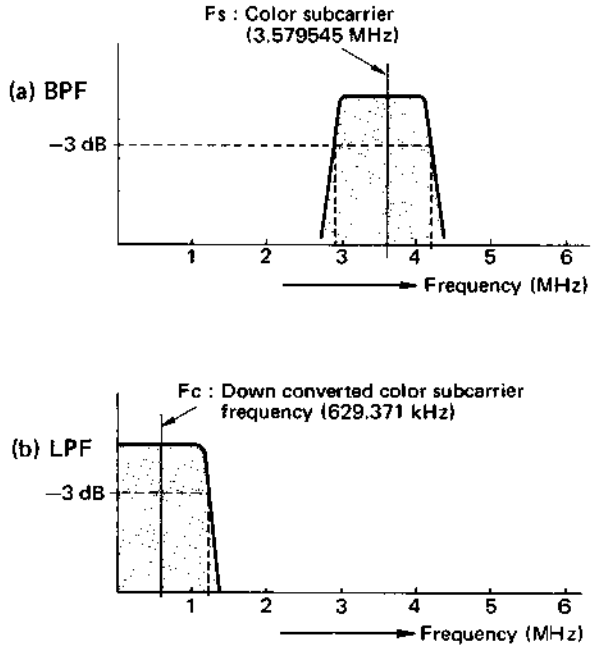

Fig. 1-49 Color signal recording bandwidth

1.6 COLOR SIGNAL PLAYBACK SYSTEM

The color signal playback system performs essentially the opposite function as the recording system. In addition, however, important corrections must be performed for color signal frequency and phase errors introduced by variations in tape speed and head rotation, and elasticity of the tape.

Fig. 1-50 indicates an abbreviated block diagram of this system.

Though a lowpass filter, the down converted color signal goes to the main converter. At this time, the down converted color subcarrier (Fc) contains an error component (40 Fh' ± Δf) due to mechanical factors of the heads and tape. Fh' varies with the tape speed as Fh ± ΔFh. Δf is the instantaneous error caused by head rotation irregularities and tape elongation and contraction.

The 40 Fh' frequency deviation component is compensated by supplying the video output signal to the horizontal sync separator, multiplier and phase shifter, and 40 Fh' to the sub converter. This forms the AFC (automatic frequency compensator) loop.

In the APC (automatic phase compensator) loop, the ± Δf phase error component is compensated by comparing the burst component of the up converted playback color signal with the subcarrier frequency from the local oscillator and APC detector. A variable crystal oscillator (VXO) produces (Fs ± Δf) which goes to the sub converter. As a result, (Fs + 40 Fh' ± Δf) is supplied as the main converter carrier input from the sub converter through a highpass filter.

By frequency conversion with Fc, the color subcarrier frequency of 3.579545 MHz, which is free from frequency and phase deviations, becomes obtained through a bandpass filter. In the opposite manner as with recording, the phase shifter delays the CH-1 track phase 90° every line, advances the CH-2 track phase 90° every line and 40 Fh' is supplied to the sub converter. The playback color signal through the main converter and bandpass filter is applied to a 1 H delay line for removing crosstalk. Characteristics of the lowpass and bandpass filters are the same as those for recording (Fig. 1-49).

At the mixer, the playback color and luminance signals are mixed to become the video output signal.

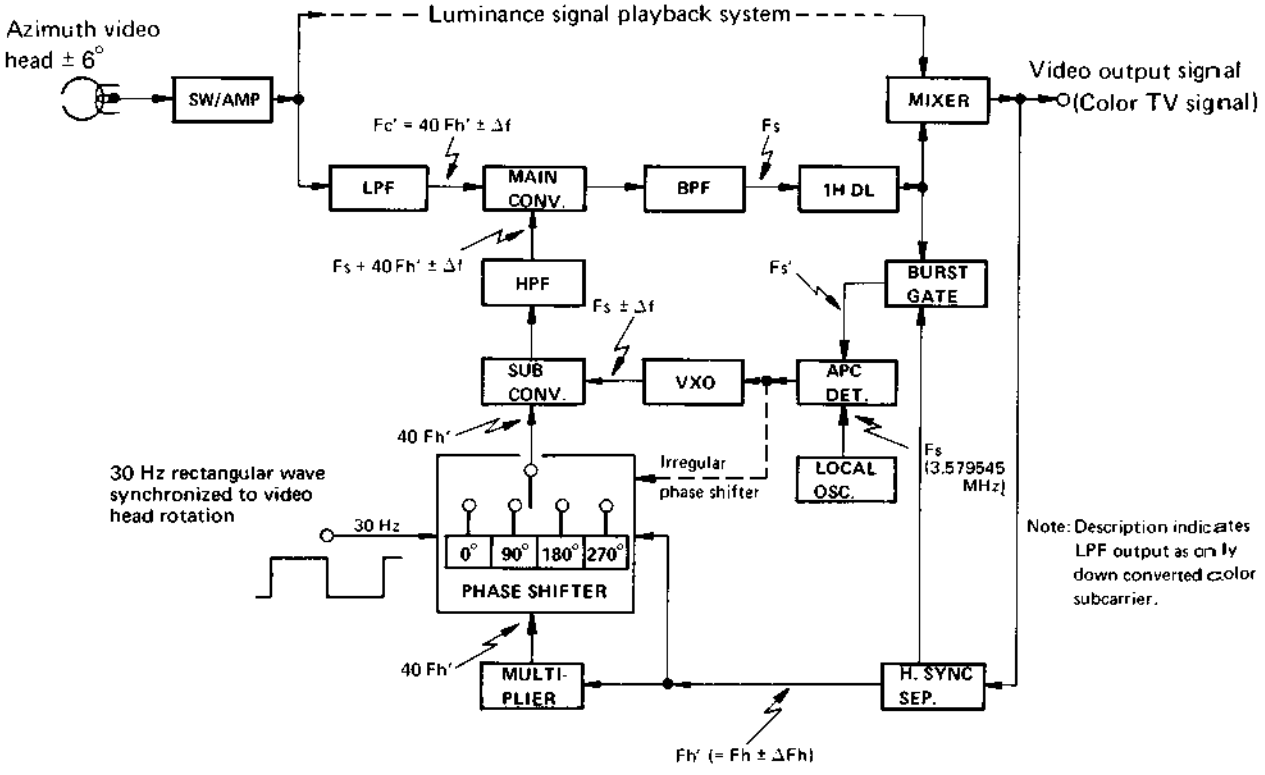

Fig. 1-50 Color signal playback system

1.7 CONTROL SIGNAL RECORDING SYSTEM

Control signal waveform, polarity and video head relationships are indicated in Fig. 1-51.

Phase of the control signal is the same as the vertical sync signal rise component of the CH-1 track. The positive pulse voltage is the reference 30 Hz.

The control signal is recorded on the control track above the saturation recording level.

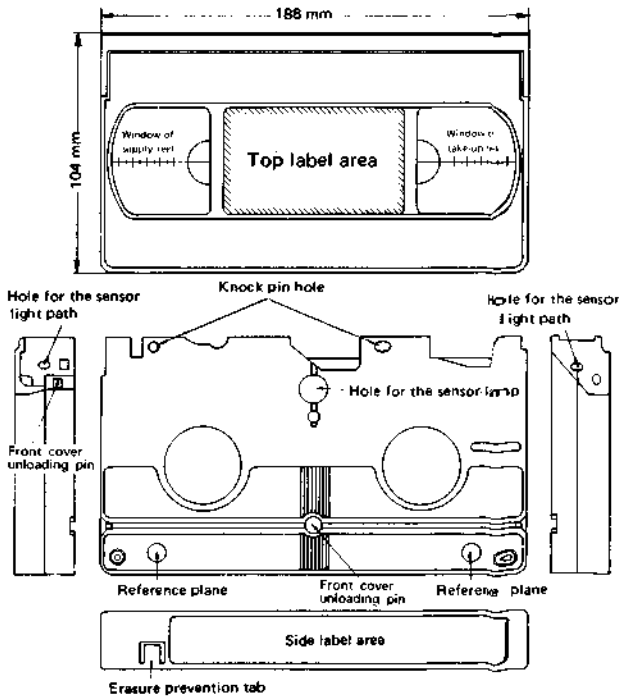

Fig. 1-54 Cassette appearance

SECTION 2
MECHANISM DESCRIPTION

2.1 TAPE TRANSPORT SYSTEM

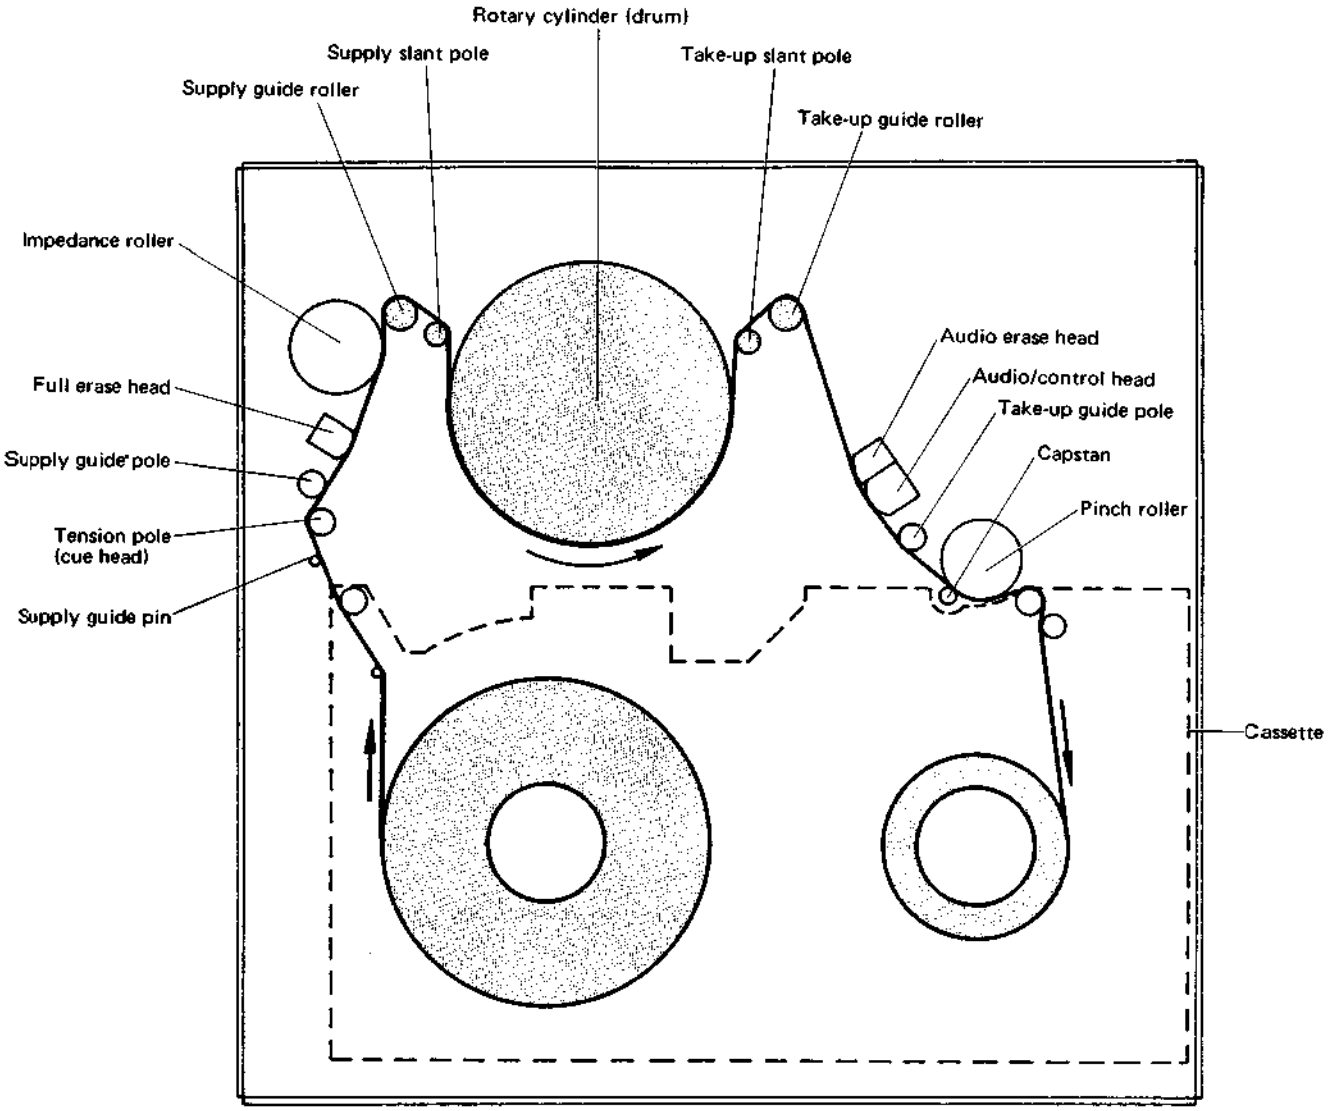

Fig. 2-1 Tape transport system

As the designation implies, the most basic function of this system is to transport the tape past the audio and video heads at the specified speed. However, since this model is a helical scan cassette type machine, numerous addition functions are required, which include extracting the tape from the cassette, wrapping it about the cylindrical head drum at a precisely defined angle, and returning the tape to the cassette after it is no longer needed.

To ensure smooth operation, conformance with VHS specifications and "interchangeability" (which allows a tape recorded by one machine to be played by another machine of the same format), the positions, heights and inclination angles of the various fixed and movable tape guides must be adjusted and maintained to close tolerances. The most stringent and difficult of these adjustments have been performed at the factory under controlled conditions. Therefore, in service, it is usually only necessary to perform minor adjustments to compensate for wear and after replacing certain internal parts.

The following description covers the mechanical states for the various operating modes. An adequate understanding of the mechanical processes is essential before attempting to repair or adjust the transport system.

2.2 MAIN COMPONENT OPERATIONS

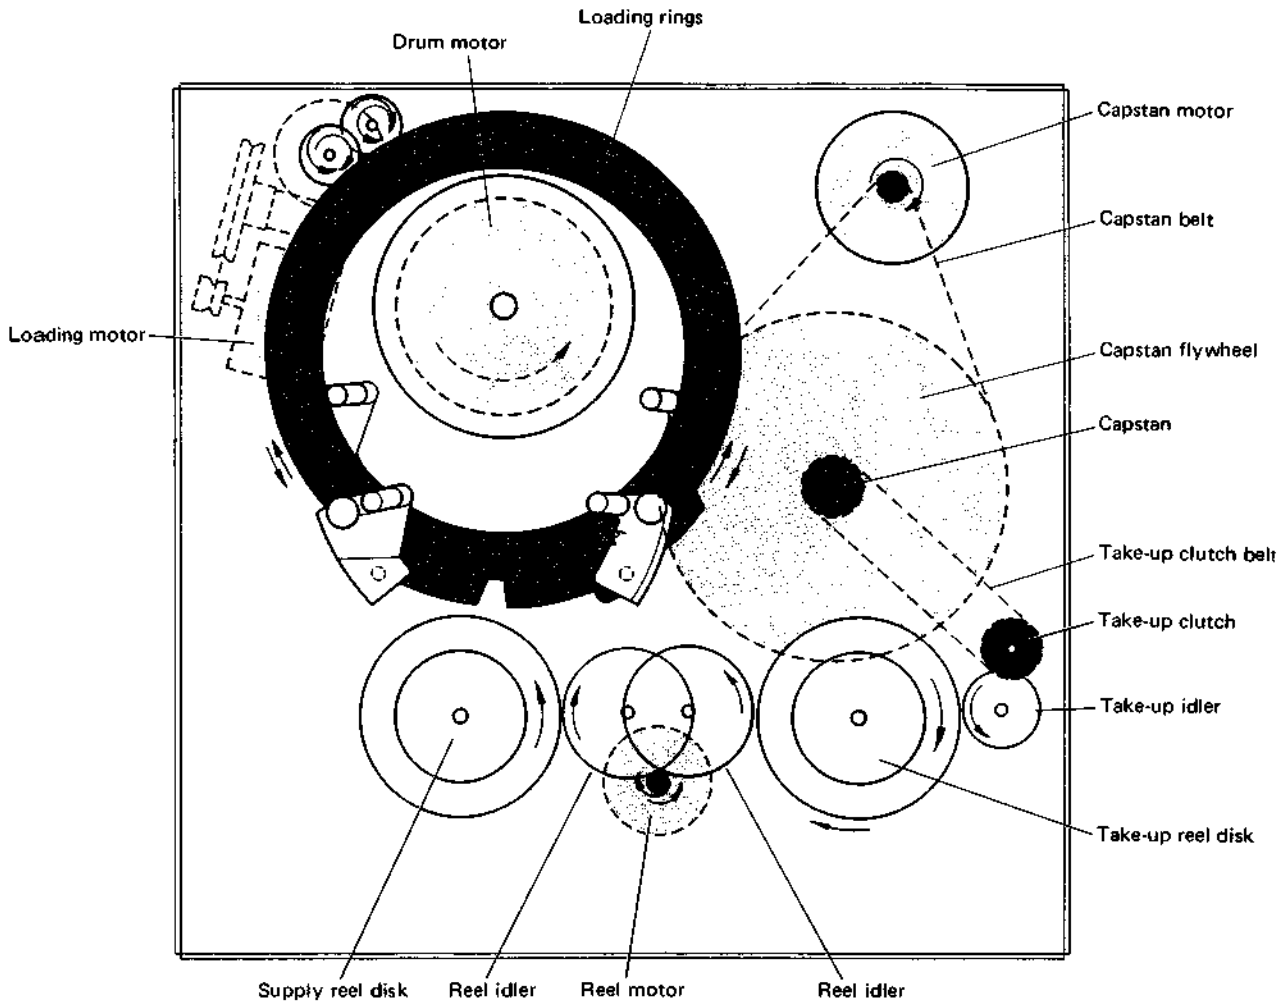

Fig. 2-2 Motor operations

2.2.1 Drum motor

Drives the rotating video heads.

2.2.2 Capstan motor

Drives the capstan via the capstan belt.

1. Rotation of the capstan motor is applied via the capstan belt to the capstan flywheel, then to the capstan.
2. Capstan flywheel rotation is transmitted by the take-up clutch belt and drives the take-up idler.

2.2.3 Reel motor

Drives the reel idler in forward and reverse directions.

2.2.4 Loading motor

Drives the loading rings in forward and reverse directions.

1. The loading motor rotation goes via the loading belt to the loading gear train composed of worm, wormwheel and relay gears. The supply loading ring is driven via the worm and wormwheel gears, while drive for the take-up loading ring is transmitted by the relay gear.

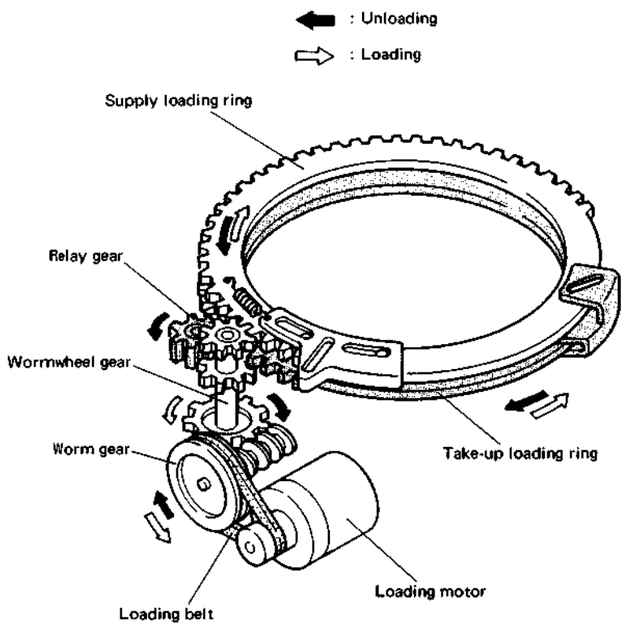

Fig. 2-3 Loading ring drive mechanism

2.2.5 Brake solenoid

Via the brake arm, this solenoid controls operation of the main brakes and the reel idler functions.

1. When the brake solenoid energizes, the brake arm turns clockwise about the fulcrum. Via the stud at the bottom of the idler plate, the brake arm rotation slides the idler plate in the forward direction. At this time, the stud atop the idler plate releases the main brakes from the reel disks.
2. If the reel idler is positioned at either the supply or take-up reel disk when the brake solenoid switches off, the idler plate returns to its original position and the idler arm returns the reel idler to the center position.

2.2.6 Pinch (roller) solenoid

This controls operation of the pinch roller, take-up idler and back tension arm.

1. When the pinch solenoid energizes, the pinch roller spring holder turns the pinch roller arm counter-clockwise to engage the pinch roller with the capstan.
2. Simultaneously with activation of the pinch solenoid, the pinch roller connect plate slides rearward. The take-up idler, which had been retained by this plate, then moves by spring force to engage the take-up clutch and take-up reel disk.
3. While the back tension brake is engaged, as the pinch solenoid switches off, spring force shifts the back tension cancel plate towards the right. The plate presses against the back tension arm, reducing the application of the back tension brake. This is performed at the start of unloading and during the search (FF and REW) modes.

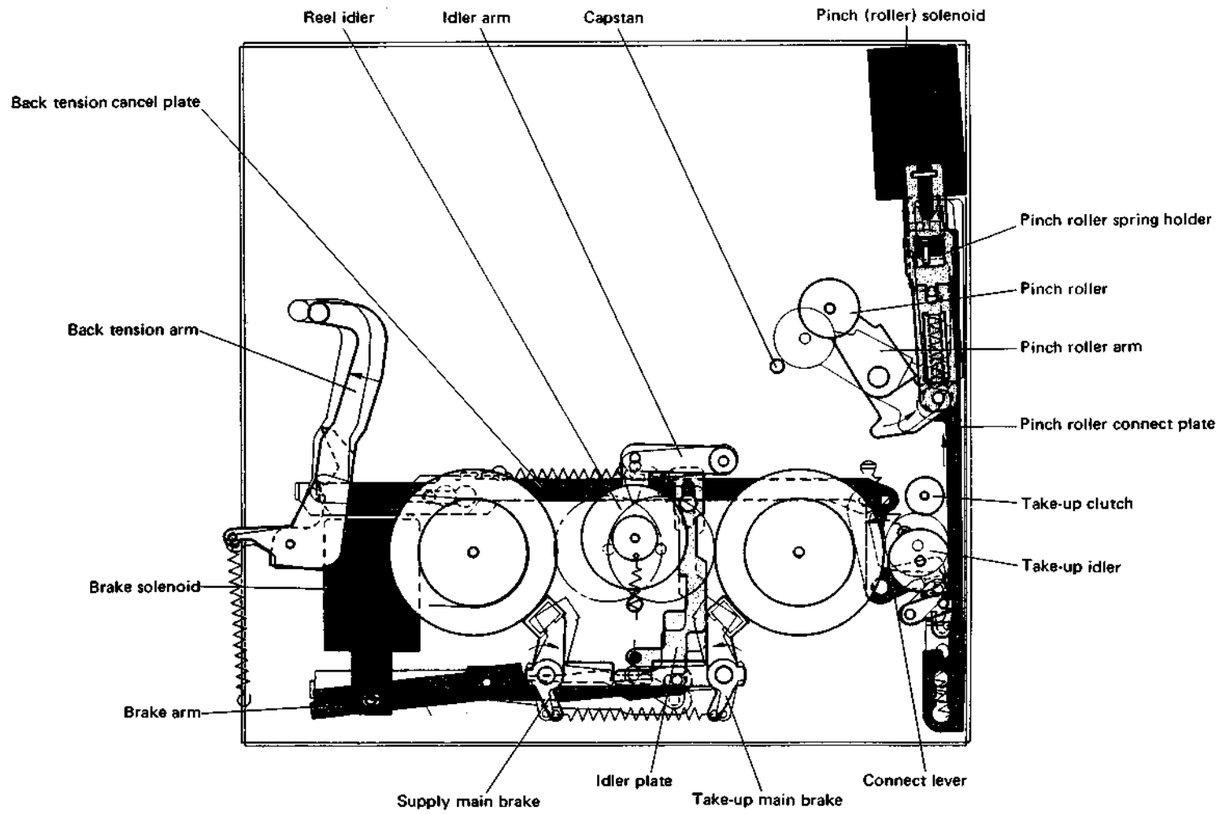

Fig. 2-4 Solenoid operations

2.3 MODE DESCRIPTION

2.3.1 Stop mode

This is the state which allows a cassette to be inserted or removed from the machine. In this mode, the motors and solenoids are not electrically functioning.

At this time, the supply pole base, take-up pole base and tension pole (with cue head) are positioned within the cassette perimeter in readiness for extracting the tape from the cassette. The pinch roller is separated from the capstan and positioned so as not to interfere with cassette insertion or removal.

The main brakes are applied to both the supply and take-up reel disks to prevent uncontrolled rotation. The reel idler is stopped and separated from both the supply and take-up reel disks. The unloading (UL) switch is on and the after loading (AL) switch is off.

NOTES:

1. Short rewind
   In the stop mode, when the EJECT button is pressed for removing a cassette, a short rewind (about 400 m-sec) operation is performed, then the cassette is ejected. Pressing the EJECT button switches the brake solenoid on, at which time the idler plate shifts in the forward direction and the reel idler contacts the reel motor shaft. Simultaneously, the reel motor turns counter-clockwise to force the reel idler toward the supply reel disk. The main brakes are released in this period. This operation serves to avoid tape slackening in the cassette.

2. Short FF
   During the stop mode, if the inserted cassette has the tape completely wound on the supply reel, or after the completion of full rewind, the start sensor detects the transparent leader tape and a short fast forward operation is performed.

   When the transparent section of tape is detected, the brake solenoid switches on, shifting the idler plate in the forward direction. The reel idler contacts the reel motor shaft, at which time the motor turns clockwise to shift the reel idler toward the take-up reel disk. In this period, the main brakes are released. This operation serves to protect the drum assembly (including video heads) from the tape leader section.

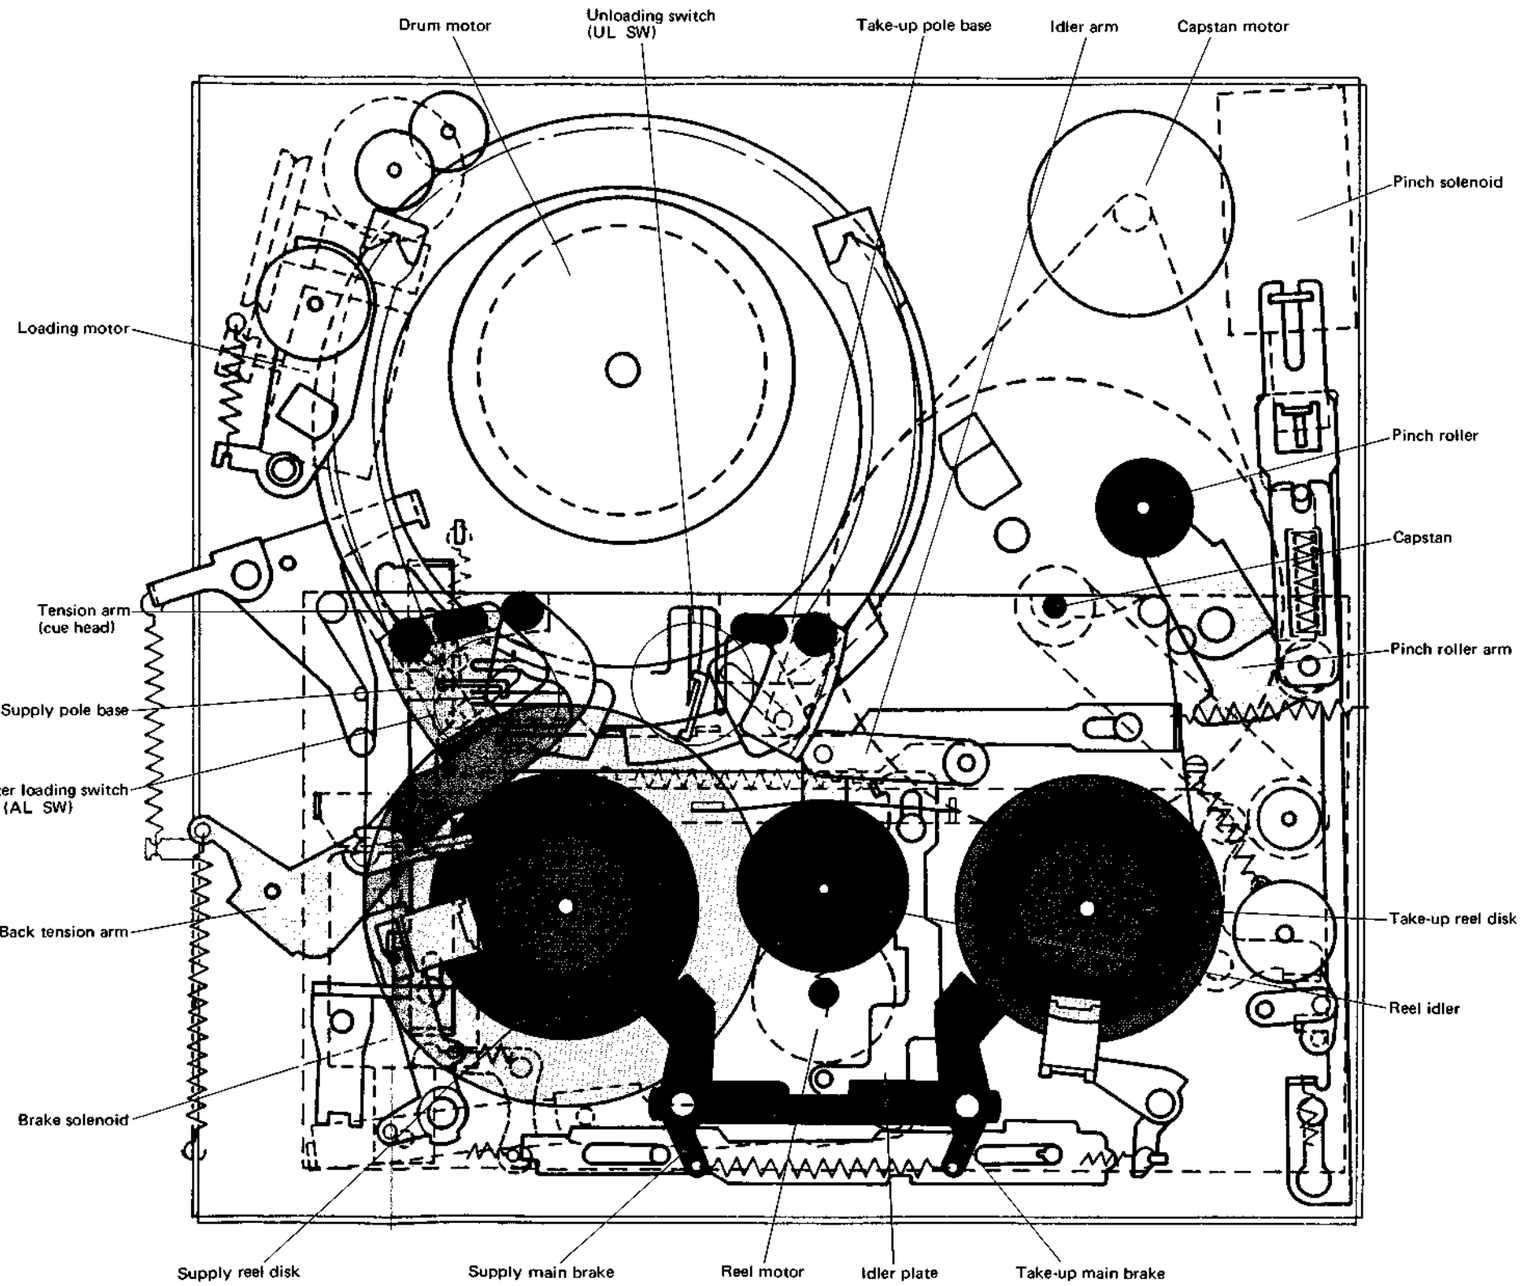

Fig. 2-5 Stop mode

2.3.2 Loading mode

The loading mode covers the process of extracting the tape from the cassette and positioning it in the transport.

In the stop mode, pressing the PLAY button switches on the brake solenoid, and the loading and capstan motors begin rotating. The brake solenoid releases the main brakes from the reel disks, thereby reducing load on the tape. However, since complete absence of load could cause tape slackening due to inertia, the loading tension brake is applied to the supply reel disk and the take-up back tension brake to the take-up reel disk.

Loading motor rotation is transferred via the loading belt to the loading rings. Slide rings are incorporated with the loading rings.

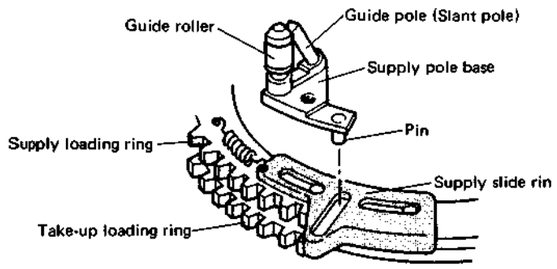

Fig. 2-6 Loading rings

The pole bases are positioned atop the sub deck. As the pins at the bottoms of the pole bases ride in the slide ring grooves, rotation of the loading rings becomes transmitted directly to the pole bases, which shift in the sub deck guide grooves. At this time, the slant poles of the pole bases and the guide rollers extract the tape from the cassette.

When the take-up loading ring begins turning, spring force shifts the pinch roller arm push plate toward the right. This imparts counter-clockwise rotation to the pinch roller arm, moving the pinch roller slightly towards the capstan and switching off the UL switch. The drum motor then begins rotating.

After the supply pole base shifts, spring force turns the back tension arm counter-clockwise. When the back tension arm strikes the cancel lever, it stops until completion of loading. Then with further movement of the cancel lever, it again turns counter-clockwise by spring force.

As loading continues, the supply pole base presses the erase head arm to carry the tape. When the supply pole base reaches a certain point, spring force returns the erase head arm to its original position and the impedance roller contacts the tape. The impedance roller serves to dampen vertical vibration of the tape, which can contribute to picture jitter and audio wow & flutter.

The pole bases engage the pole guides of the sub deck and stop. However, the loading rings continue to rotate until the switch plate sets the AL switch on.

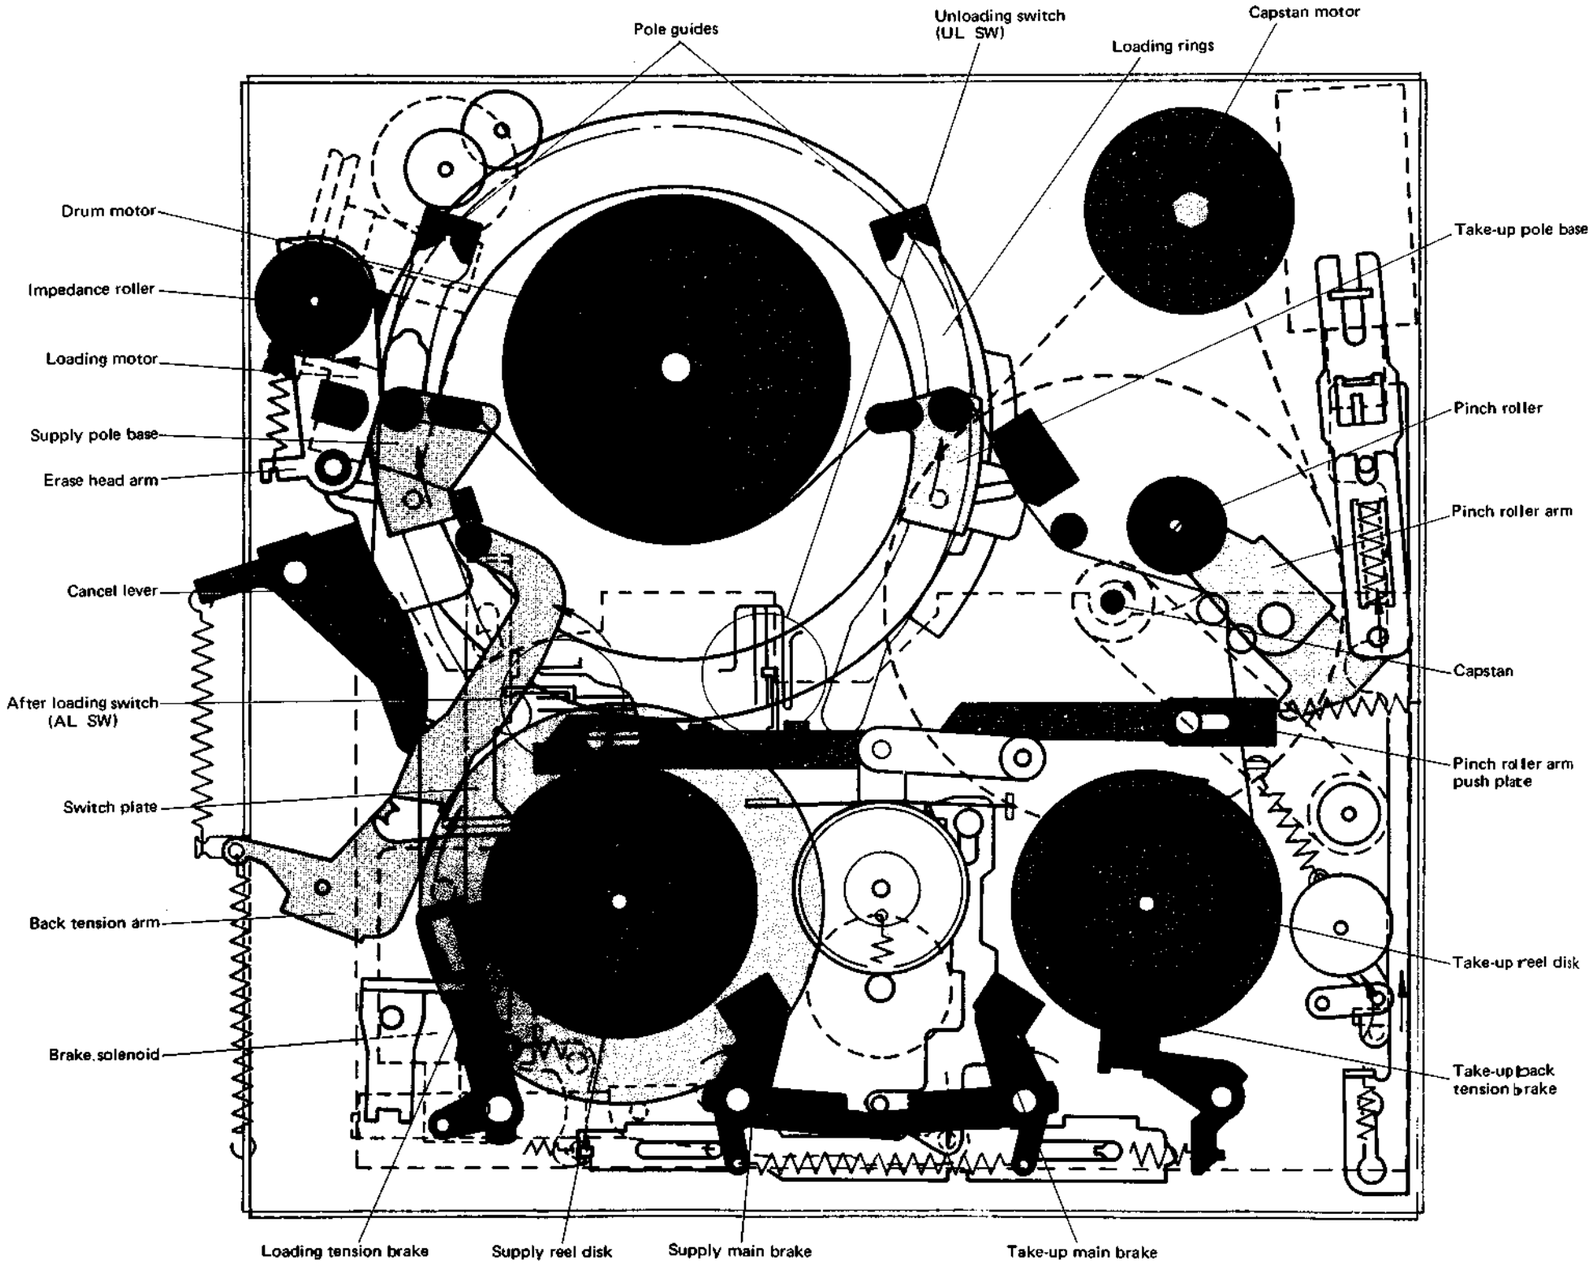

Fig. 2-7 Loading mode

2.3.3 Play mode

1. Normal play and recording

   After the pole bases engage the pole guides, the loading rings continue to turn. The stud at the bottom of the take-up loading ring imparts counter-clockwise rotation to the cancel lever, which shifts the switch plate in the forward direction. This sets the AL switch on, stopping the loading motor and loading rings. At the same time, the switch plate presses and releases the loading tension brake. The switch plate also imparts counter-clockwise rotation to the change lever, shifting the connect plate toward the right and releasing take-up back tension brake.

   The AL switch sets the pinch solenoid on and the take-up idler transfers the take-up clutch rotation to the take-up reel disk. When tape take-up begins, the pinch roller engages the capstan to initiate tape transport.

   When the pinch solenoid energizes, the reel motor turns briefly clockwise, shifting the reel idler toward the take-up reel disk. Since rotation of the take-up reel disk acts to brush aside the reel idler, load is not imposed on the disk. Also, this action is not sufficiently strong to overcome the plate spring force and shift the reel idler toward the supply reel disk.

2. Still and frame advance

   In the play mode, when the STILL button is pressed, the servo system functions to correct the FM noise position in accordance with instructions from the mechacon circuit. The pinch roller and take-up idler remain engaged. At first, the tape is transported toward the take-up reel by intermittent rotation of the capstan motor, then the motor stops.

   At this point, the mechanical state is the same as the normal play mode, but in absence of capstan motor rotation, the tape is stopped. The pinch roller and take-up idler remain engaged, while the drum motor continues to rotate.

   During the still mode, by pressing the FR ADV (frame advance) button, the capstan motor rotates to transport the tape toward the take-up reel. Otherwise, the mechanical state is the same as the still mode.

   Again pressing the PLAY button returns the normal play mode. The capstan motor rotates and tape transport resumes.

3. x2 (double speed)

   During the normal play mode, pressing the x2 button doubles the capstan motor speed. Otherwise, the mechanical state is the same as the play mode. Again pressing the PLAY button returns the normal play mode.

4. Slow speed

   By pressing the SLOW button in the play mode, the capstan motor rotates intermittently to transport the tape toward the take-up reel at reduced speed. Otherwise, the mechanical state is the same as the play mode. Tape speed during the low mode can be adjusted by the front panel SLOW SPEED control. Again pressing the PLAY button returns the normal play mode.

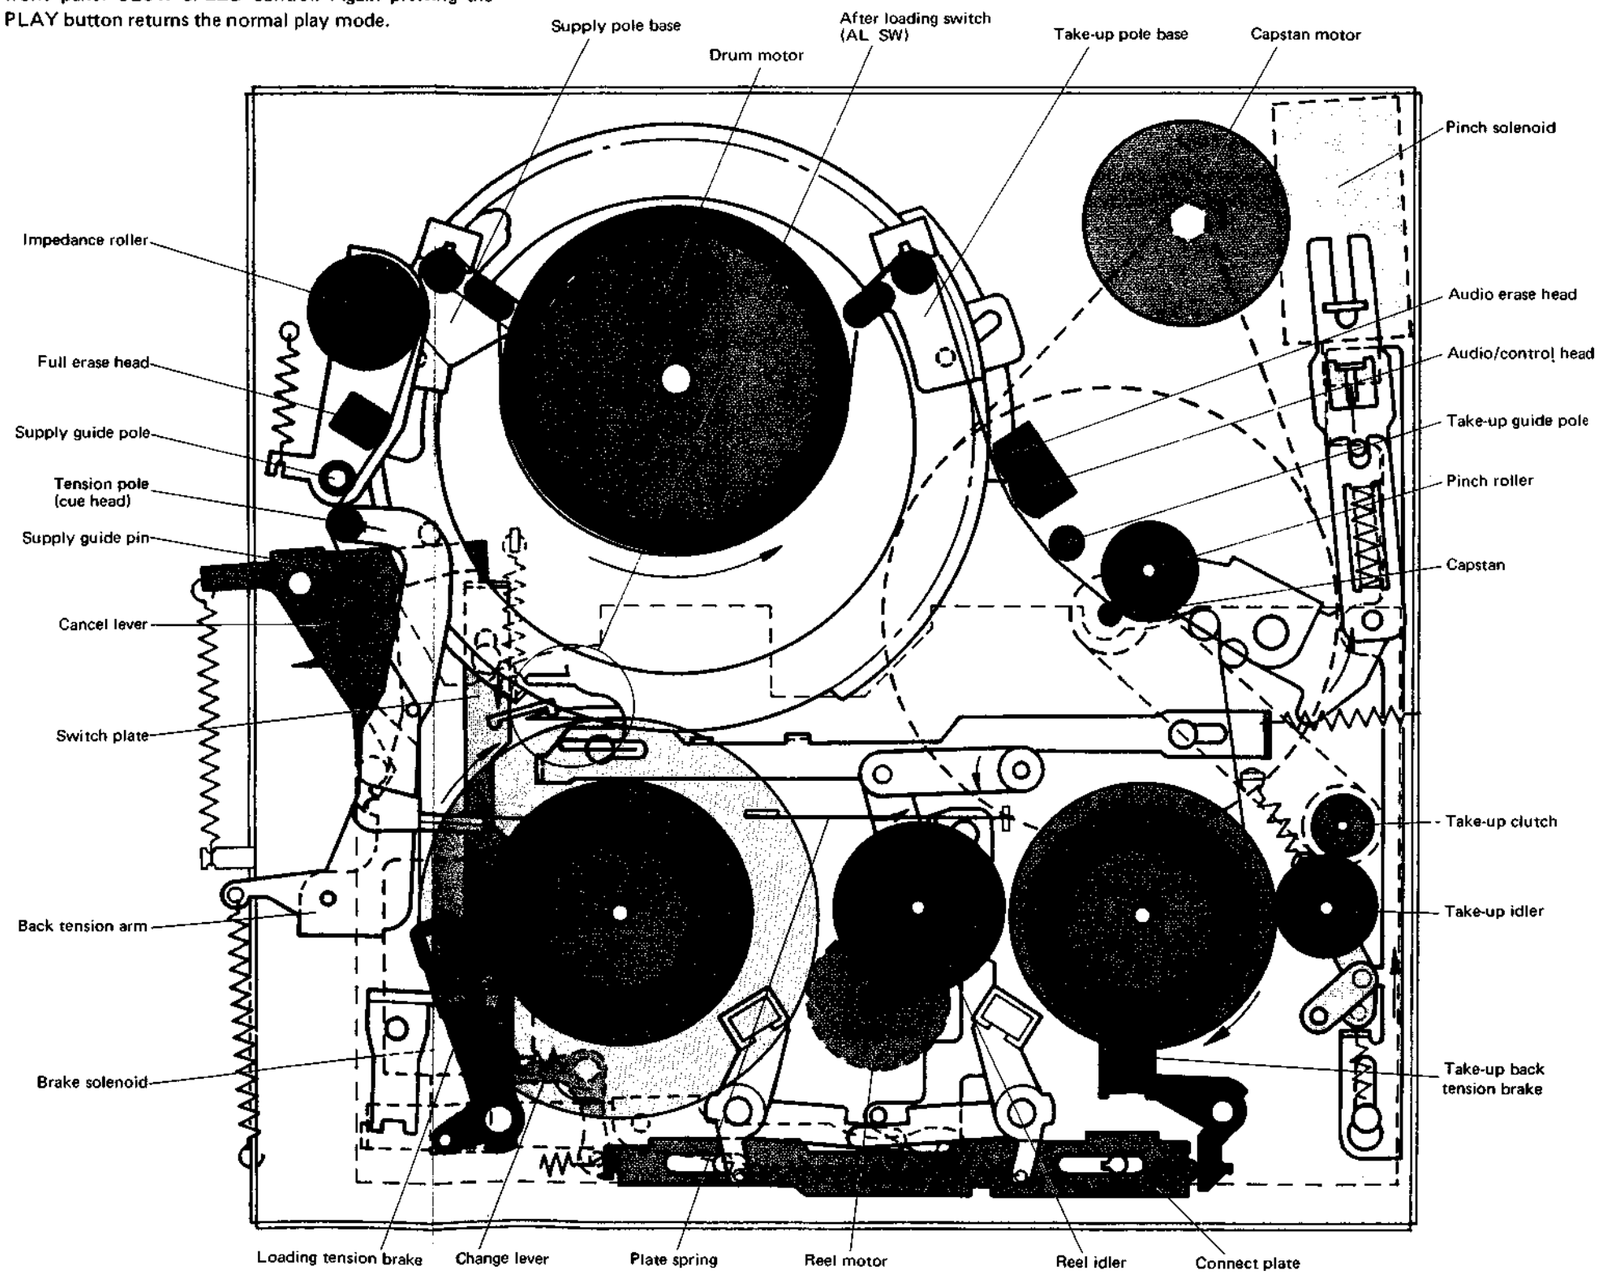

Fig. 2-8 Normal play mode

5. Recording pause

When the PAUSE button is pressed in the recording mode, the capstan motor rotates slightly in reverse to perform 25 frames back spacing. At the same time, the brake solenoid briefly switches off and the idler plate moves toward the rear, shifting the reel idler from the take-up reel disk to the center position.

Immediately afterwards, the reel motor turns counter-clockwise and this shifts the reel idler toward the supply reel disk. Using the reel motor, tape transported by reverse rotation of the capstan becomes taken up by the supply reel.

At completion of tape winding, the brake solenoid again switches off briefly. The idler plate moves rearward to shift the reel idler to the center. The reel motor then turns clockwise to again shift the reel idler toward the take-up reel disk. Tape slack at the take-up side produced during the back space operation becomes absorbed by this process.

The capstan motor stops after back space rotation. At this time, the mechanical state is the same as for recording. The pinch roller and take-up idler remain engaged and the drum motor continues to rotate. However, the capstan motor and tape transport are stopped.

Again pressing the PLAY button returns the recording mode.

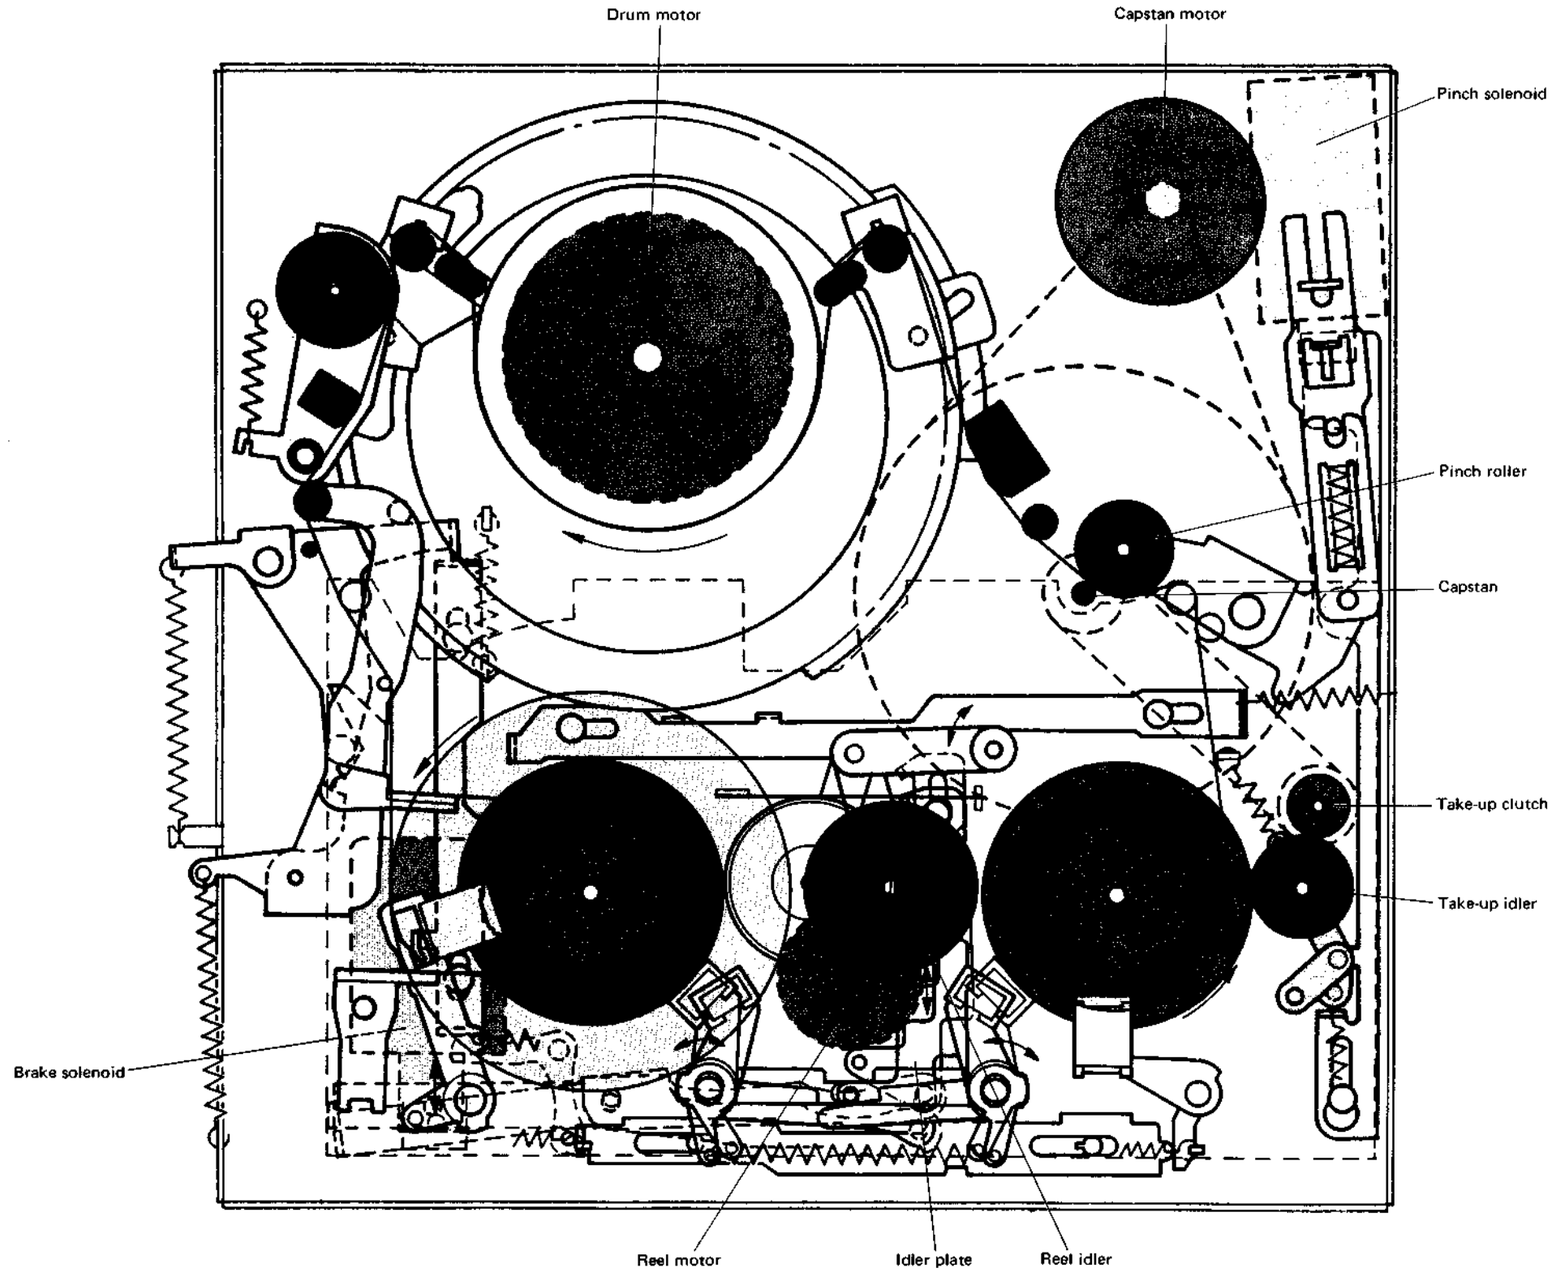

Fig. 2-9 Recording pause mode (process)

6. Search FF

In the normal play mode, holding the FF button depressed switches the pinch solenoid off, while the reel motor turns clockwise at increased speed. The capstan motor continues to rotate.

When the pinch solenoid switches off, the tape transport stops and the back tension cancel plate shifts the back tension arm to reduce back tension. The reel idler transfers the increased reel motor rotation to the take-up reel disk. With back tension reduced, the tape becomes taken up by the take-up reel at about 9 times the normal play speed.

Releasing the FF button briefly sets the brake solenoid to off, applying the main brakes to the reel disks, and the reel motor stops. At the moment the brake solenoid switches off, the reel idler returns to center position, then when the reel motor turns briefly clockwise, the reel idler shifts toward the take-up reel disk.

At the same time, the pinch solenoid switches on, then the brake solenoid again switches on to resume the normal play mode.

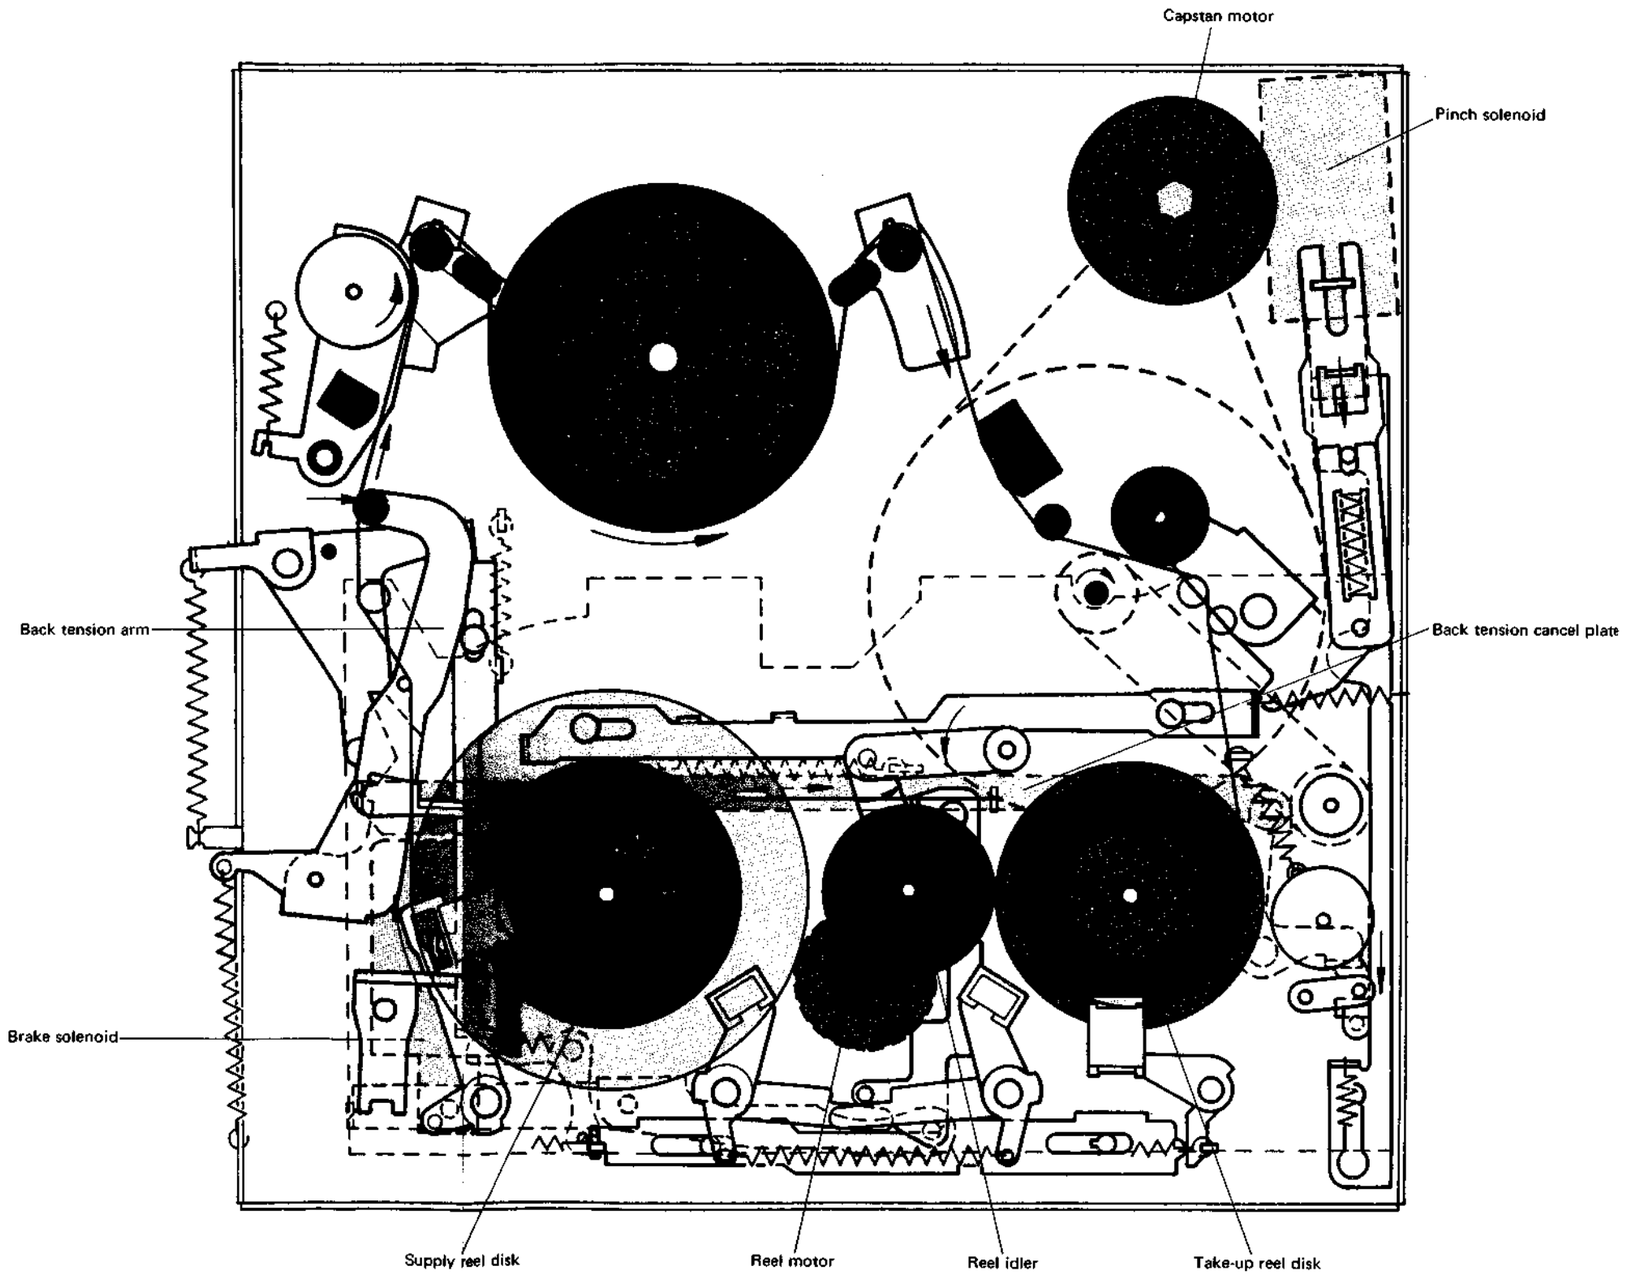

Fig. 2-10 Search FF mode

7. Search rewind

During the normal play mode, holding the REW button depressed briefly switches off the brake solenoid. The main brakes become applied and the reel idler returns to center.

The brake solenoid returns to on and the reel motor turns counter-clockwise to shift the reel idler toward the supply reel disk. At the same time, the pinch solenoid switches off to stop the tape transport and reduce back tension. The capstan motor also stops.

The reel motor then rotates at increased speed, which is transmitted by the reel idler to the supply reel disk. With back tension reduced, the tape becomes wound on the supply reel and transported at approximately 9 times the normal play speed.

Releasing the REW button briefly switches the brake solenoid off. The main brakes are applied to the reel disks and the reel motor stops. The reel motor then turns briefly clockwise to shift the reel idler from the supply to the take-up reel disk. At the same time, the pinch solenoid switches on and the capstan motor rotates to resume the normal play mode.

During search rewind, both the supply and take-up reel disks rotate at increased speed. After the reel motor stops, they continue to turn due to inertia. However, at this time, tape slack produced at the take-up side becomes impeded by the load produced between the oilless metal bearing and collar of the take-up reel disk.

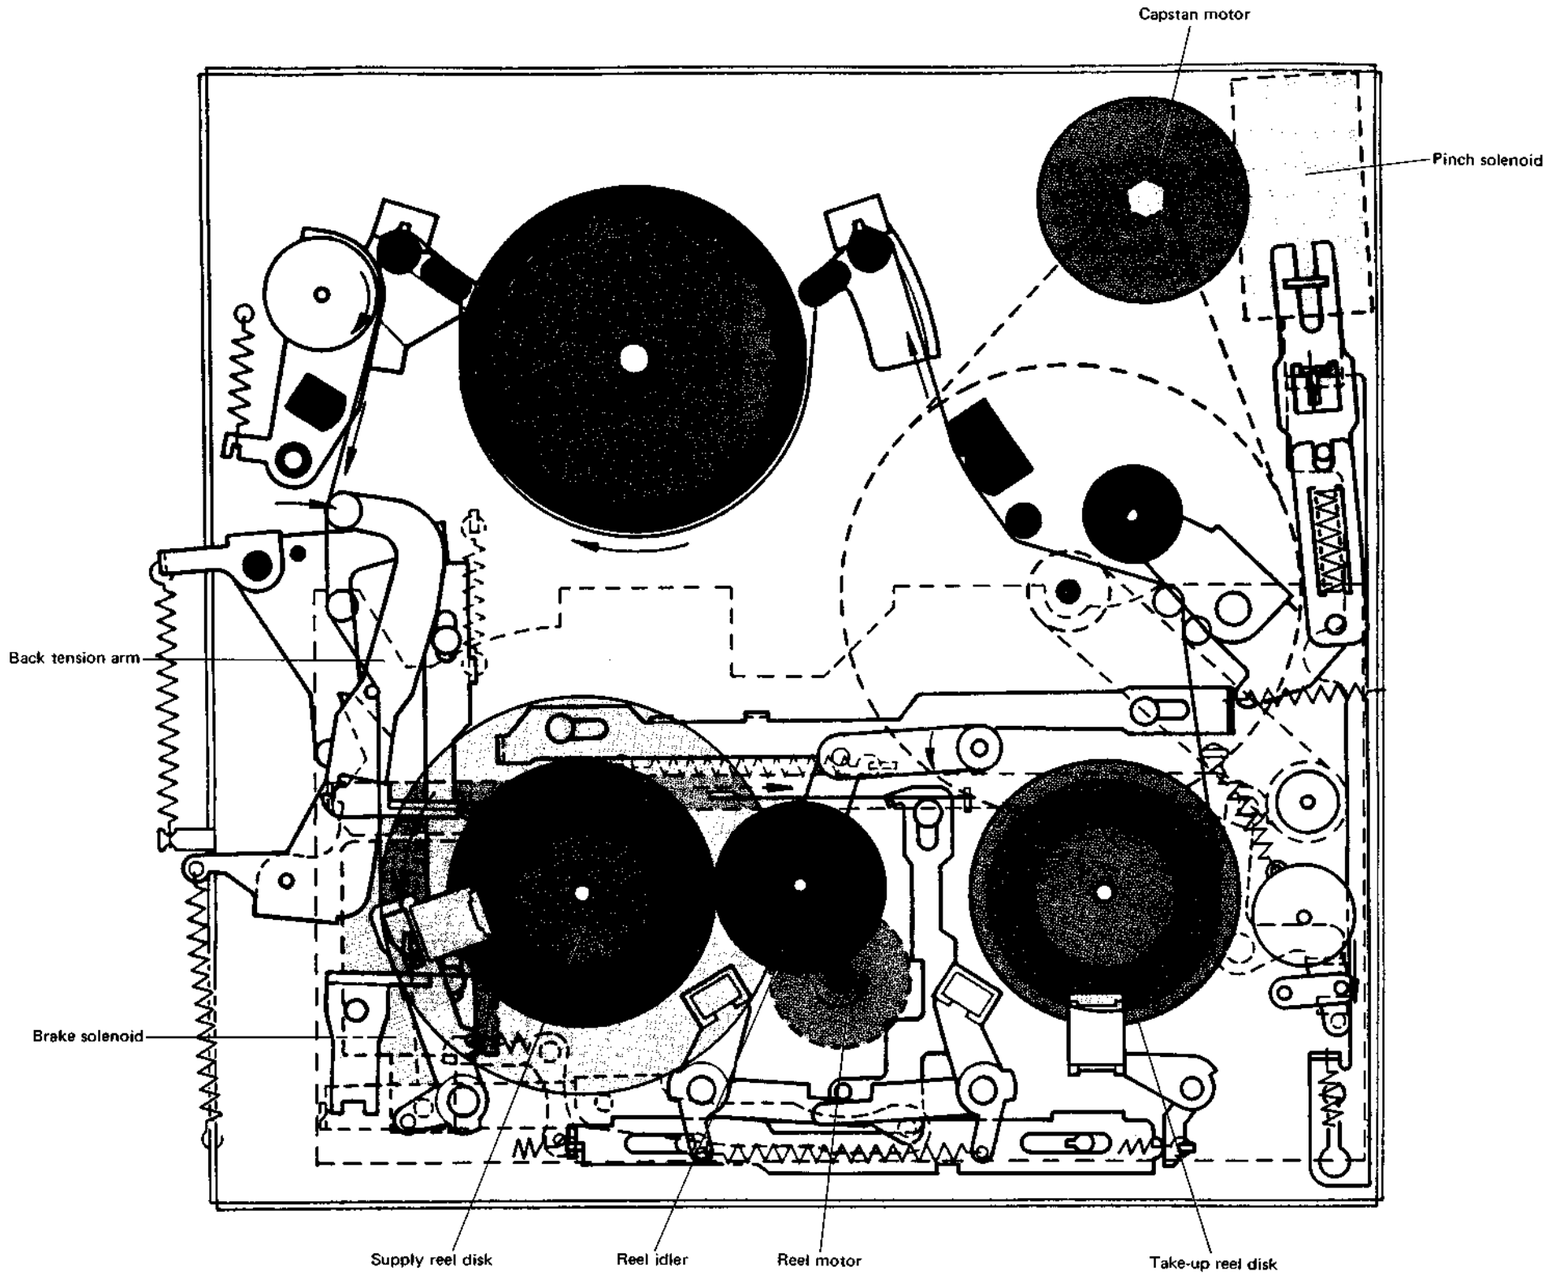

Fig. 2-11 Search REW mode

2.3.4 Unloading mode

At the end of tape in the normal play mode, or if the STOP button is pressed, the pinch and brake solenoids switch off and tape transport stops. The brake solenoid again switches on to release the main brakes, while the reel motor turns counter-clockwise to shift the reel idler toward the supply reel disk. The loading motor turns to move the pole bases toward the cassette.

Spring force imparts counter-clockwise rotation to the cancel lever and the back tension arm turns clockwise. While pressing the back tension arm, the supply pole base proceeds to within the cassette. In this manner, the tape extended from the cassette becomes wound on the supply reel.

When the supply pole base, back tension arm and take-up pole base become positioned within the cassette, the slide ring of the take-up loading ring shifts the pinch roller arm push plate towards the left. This completely separates the pinch roller from the capstan and sets the UL switch on. The loading, reel, capstan and drum motors stop, and the brake solenoid switches off to yield the stop mode.

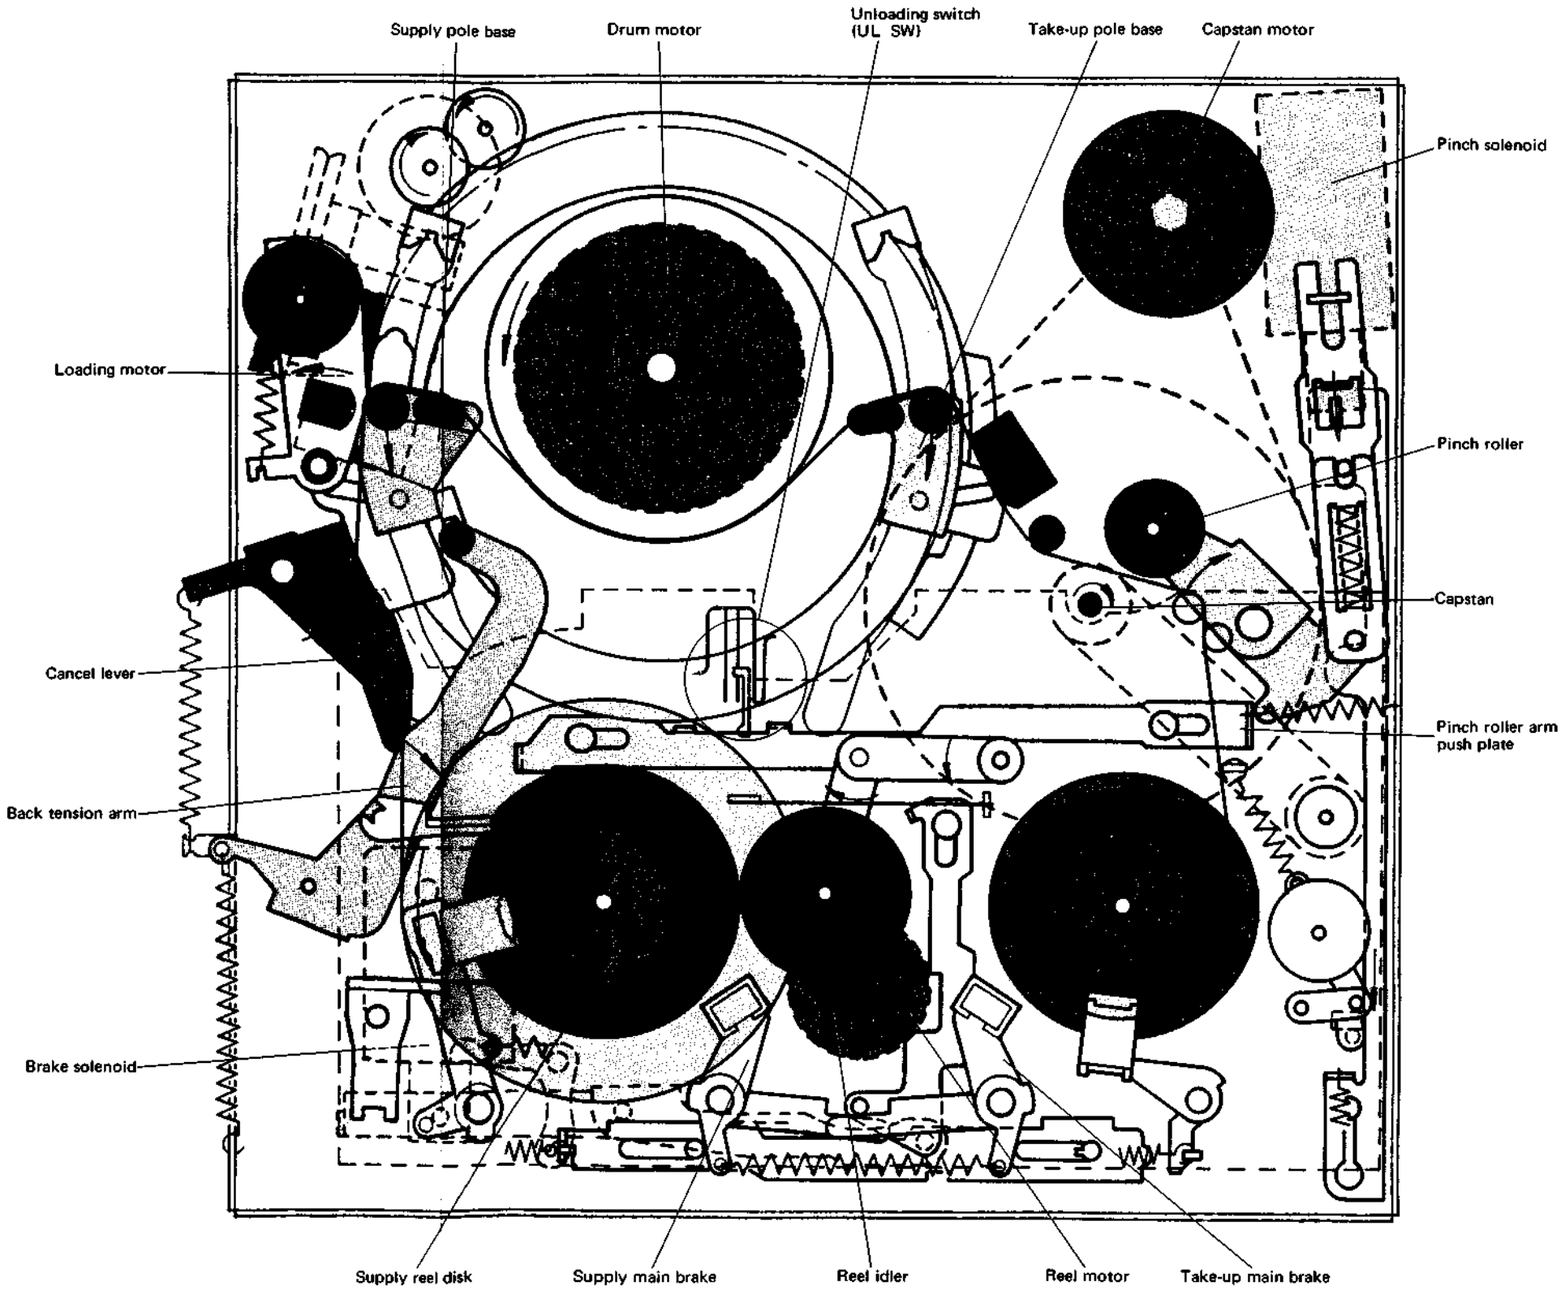

Fig. 2-12 Unloading mode

2.3.5 Fast forward (FF) mode

In the stop mode, pressing the FF button sets the brake solenoid on. The main brakes are released, the reel motor turns clockwise, and the reel idler contacts the take-up reel disk. Initially, the reel motor rotates at reduced speed, then at higher speed to transport the tape to the take-up reel. This stepped rotation serves to avoid sudden load on the tape.

The loading tension brake and take-up back tension brake remain engaged in order to impart a fixed tension. This serves to promote both proper tape winding and accurate pickup of the cue signal.

When the STOP button is pressed, the reel motor stops. The brake solenoid switches off and the reel idler returns to center position. At the same time, the main brakes are applied to the reel disks and tape transport stops.

At the end of tape in the FF mode, the end sensor functions to initiate auto rewind.

If the counter SEARCH switch is on, FF becomes performed at reduced speed in the range of 9900 to 0000 as indicated by the counter. This permits more precise stopping at the 0000 point.

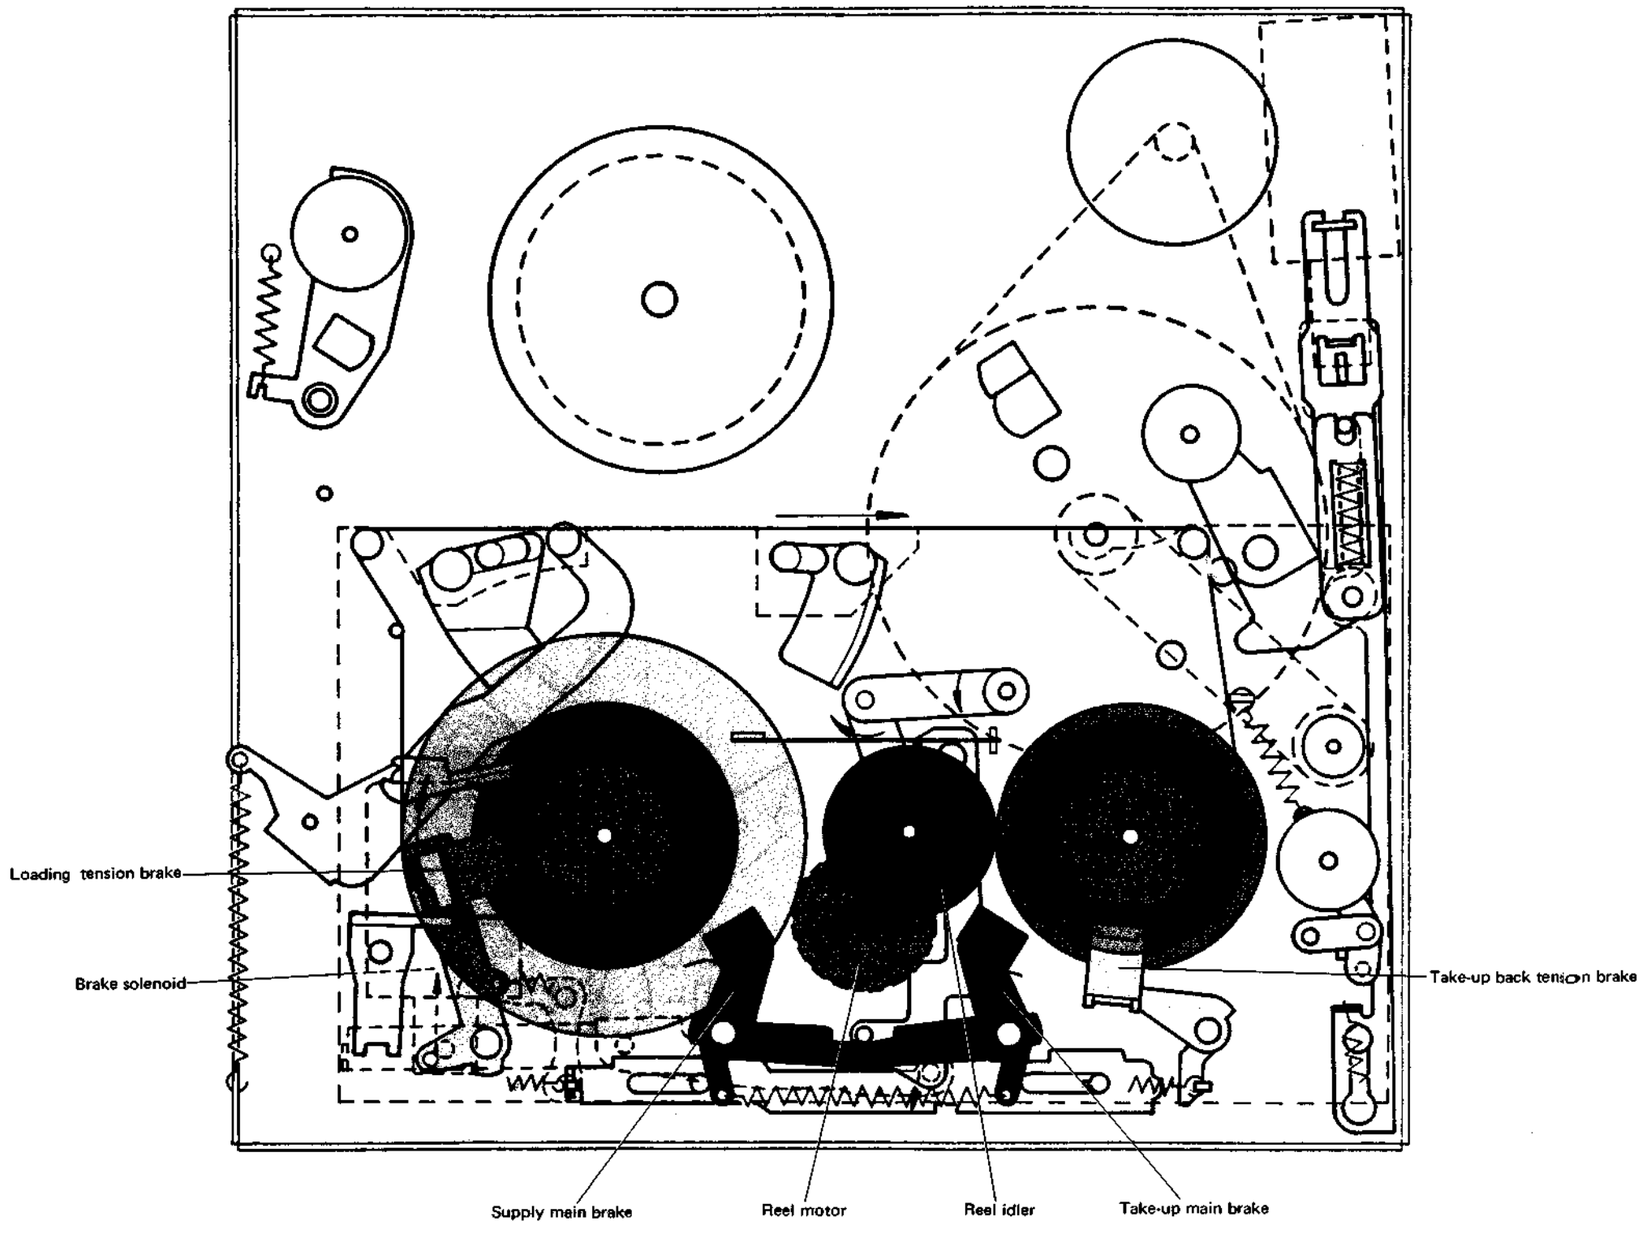

Fig. 2-13 FF mode

2.3.6 Rewind (REW) mode

In the stop mode, pressing the REW button sets the brake solenoid on. The main brakes are released and the reel motor rotates counter-clockwise to shift the reel idler toward the supply reel disk. Following this, the reel motor turns at reduced speed, then at higher speed. This is to avoid sudden load on the tape.

The loading tension and take-up back tension brakes remain engaged in order to promote smooth tape winding and allow accurate detection of the cue signal.

When the STOP button is pressed, the reel motor stops. The brake solenoid switches off and reel idler returns to center. At the same time, the main brakes are applied and tape transport stops.

If the beginning of the tape is reached in the rewind mode, the start sensor functions to initiate short FF.

If the counter SEARCH switch is on, rewind is performed at reduced speed in the counter range of 0100 to 0000. This serves to allow more accurate stopping at the 0000 point.

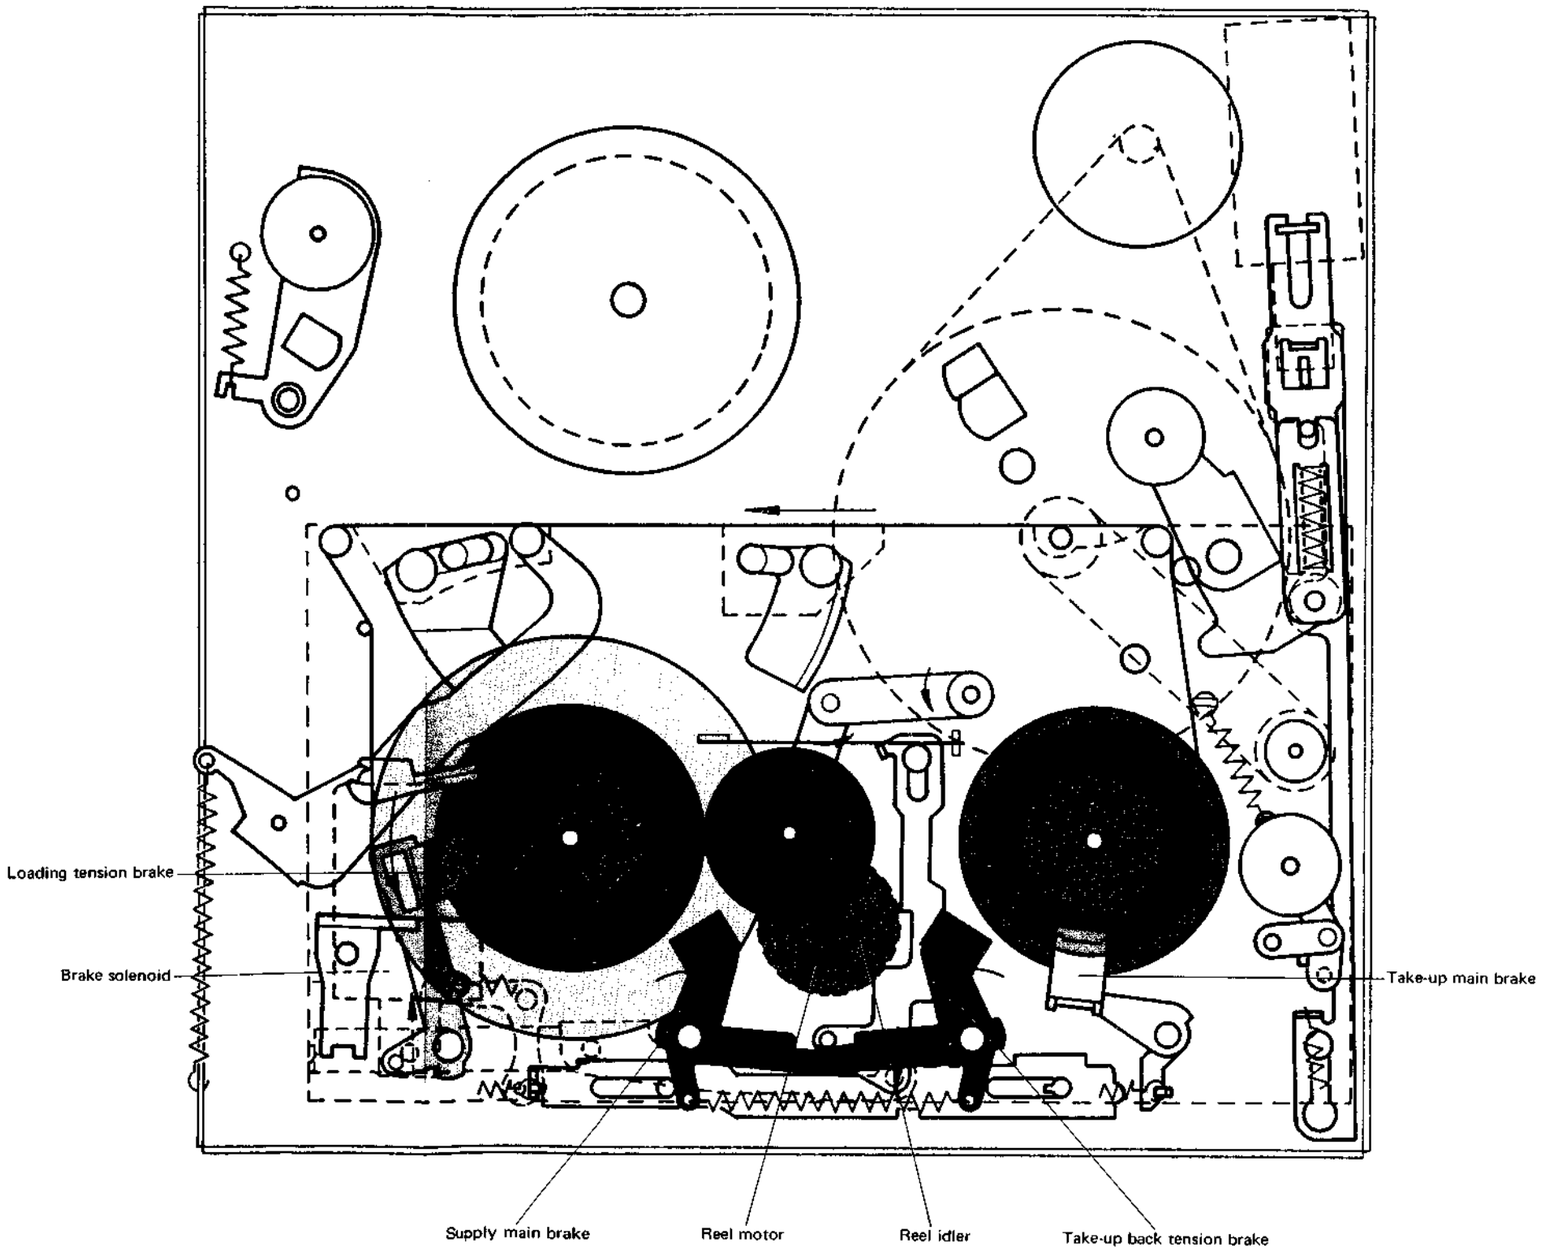

Fig. 2-14 REW mode

2.4 CASSETTE HOUSING

This model utilizes a motorized front loading system by which cassette insertion and ejection are performed by the motor of the cassette housing.

2.4.1 Neutral state

The state without a cassette inserted is shown by (a) of Fig. 2-15.

2.4.2 Cassette setting

Setting is performed automatically when a cassette is inserted into the slot.

1. When a cassette is inserted, it presses and raises the two rubber rollers of the roller assembly at the top of the cassette housing. Sprocket gear-2 turns slightly counter-clockwise and pulls the chain taut.

   The shutter blocks the photo interrupter, yielding a low signal output, and the cassette motor begins turning in the loading direction. Rotation of the cassette motor is transmitted in the route: cassette belt → worm gear → worm wheel gear → sprocket gear-1 → chain.

   The chain turns counter-clockwise and the roller assembly, coupled to sprocket gear-2, rotates to feed the cassette into the cassette housing. This is indicated by (b) in the figure.

2. As the cassette moves inward, it presses the slide plate and the chain pin of the slide plate engages a link of the chain. The pin is pressed downward by the chain and the cassette becomes lowered into the housing. This is shown by (c).

3. When the cassette is completely lowered, a roller attached to the housing closes the cassette switch. This stops the cassette motor to complete the setting process. The state at this point is indicated by (d).

NOTE: When the cassette switch closes, short brake is applied to the cassette motor, stopping the rotation. Consequently, the mounting position of the cassette switch determines the cassette setting position. Care is therefore needed when replacing the cassette switch. Refer to the mechanical adjustments of Section 4.

2.4.3 Cassette eject

The cassette becomes ejected automatically when the EJECT button is pressed. A short rewind operation is performed at the stop state (UL switch on, brake solenoid off, etc.) in order to absorb tape slack in the cassette.

1. When the EJECT button is pressed, after short rewind, the cassette motor begins turning in the unloading direction. The motor rotation is transmitted in the route: cassette belt → worm gear → worm wheel gear → sprocket gear-1 → chain. The chain engages the chain pin and the cassette is raised.

2. After the rollers of the roller assembly are contacted, they turn clockwise to slide the cassette horizontally outward.

3. At the end of travel, the chain loosens, shifting the shutter. This produces a high signal at the photo interrupter and the cassette motor stops to complete the eject process.

NOTES:

1. During cassette setting, if the cassette switch does not close within 7 seconds after the cassette motor rotates, the eject mode is entered automatically.
2. If an additional 7 seconds elapse before completion of eject, the cassette motor stops and the eject emergency mode is entered. The EJECT button LED flashes and all operating modes are inhibited.
3. If an empty cassette (which does not contain tape) or one with broken tape is inserted, the start and end sensors perform detection and the Eject mode is automatically entered.

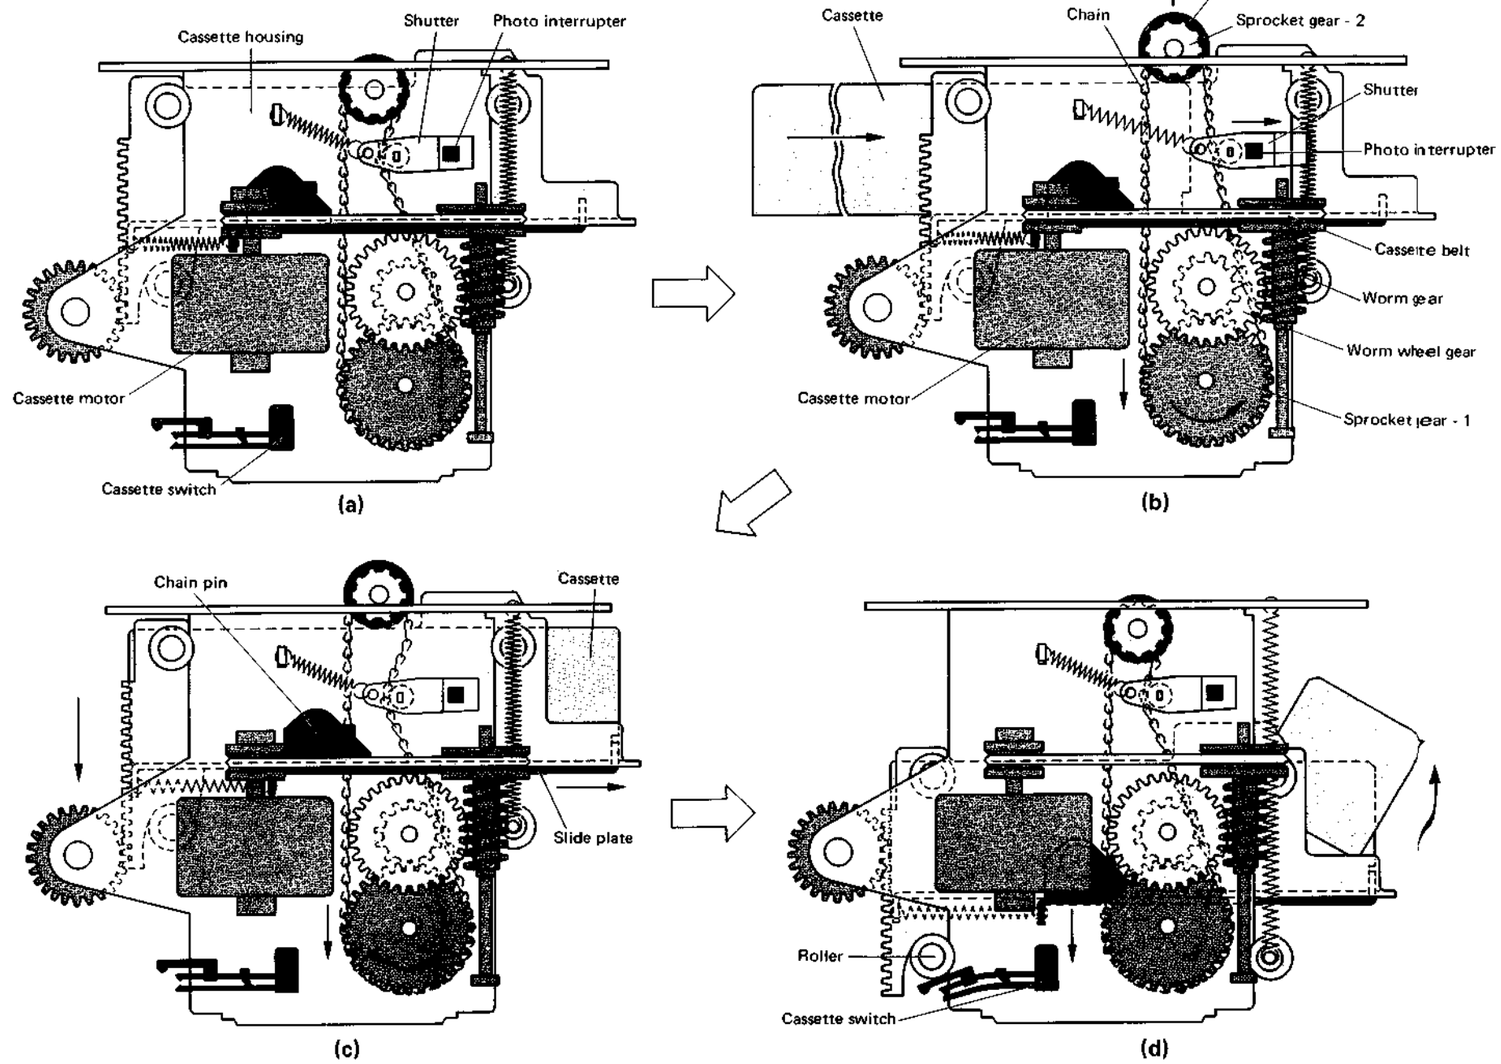

Fig. 2-15 Cassette housing mechanism

SECTION 3
CIRCUIT DESCRIPTION

3.1 MECHANISM CONTROL SYSTEM

3.1.1 General description

The mechacon circuit receives mode command signals from the operation keys and mode detect signals from the various sensors and produces signals for driving the motors and solenoids to set up the required modes. Mode control signals are also sent to the appropriate circuit boards.

These control functions are performed by the central processing unit (CPU) of IC5, which is a one-chip 4-bit microcomputer.

In the block diagram, observe that for the input side of CPU, the CPU input port has only 8 input terminals; Port A is 4-bit and Port B is 4-bit. However, the input from control keys and each sensor and other PCBs totals more than 8 inputs so that it is impossible to supply all of these inputs directly to the CPU.

For this reason, IC3 multiplexer is provided as an input expander. Using the 3-bit bus select signal from CPU port E (strobe data irrelevant), one output is selected from among seven inputs sent to the CPU input ports.

Thus, the four 7-to-1 multiplexer circuits of IC3 supply 4-bit outputs to the CPU input A ports from 28 inputs (in practice, 4 input terminals are fixed) and the remaining operation and sensor signals go directly to the input B ports.

At the same time, the four 7-bit latches of IC4 function as output expanders. The 4-bit outputs of the CPU D ports are expanded to 28 latched outputs. Latch positions are determined by the 3-bit bus select from the CPU E ports and the strobe data.

The following describes the overall operational flow.
If a given control key is depressed, a 10-bit serial code (operation code) corresponding to that mode is output by the function key code generator. The operation code is fed to IC2 after being amplified at IC1. IC2 is a serial-to-parallel decoder which converts the operation code of a 10-bit serial code into a parallel 8-bit signal. This parallel 8-bit signal is then input to multiplexer IC3 and then fed to IC5 (CPU). The CPU is capable of detecting which control key is depressed through this input data.

The CPU also detects other input port data. These include timer, cassette switch, cassette lamp and the various sensors. Data pertaining to the depressed key are checked, such as whether it is the same as the mode in progress and whether shift to a newly selected mode is possible from the present mode. Outputs corresponding to the operation key are then sent to the motors, solenoids and circuit boards.

From port D, the 4-bit output goes to IC4 latch, resulting in 28 latched outputs which are sent through open collector inverters to the circuit boards. Control signals also go to the operation board for lighting the LEDs corresponding to the depressed operation key.

Three bits of the four-bit port F output are for loading motor control. These are supplied via inverters to the control generator (consisting of four diodes) for determining motor torque and to electronic switches (Q5, Q6) which select motor direction.

For example, in the play mode, rotation is in the loading direction. When the loading mechanism begins operation and the unloading (UL) switch becomes off, the CPU detects the start of loading. At the end of loading, the after loading (AL) switch becomes on, at which time the CPU detects the end of loading and stops the loading motor. The unloading process is the opposite of this.

The 4-bit port H output is divided into 2 bits each. These go via inverters to the solenoid drive and hold amplifiers for switching the main and pinch solenoids on and off according to mode. The pinch solenoid is driven after completion of loading (AL switch on) during play and recording.

Moreover, the 4-bit output from output port D is used for controlling the cassette motor.

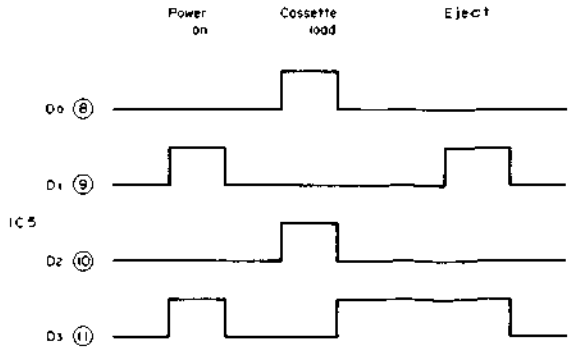

Fig. 3-1 Cassette motor control time chart

1. REEL MOTOR control

The reel motor is controlled by the output data of a total of 7 bits consisting of 3 bits of port C and 4 bits (pins 7 through 10) of the expander. The following is a brief summary of this control:

- ○ During FF/REW, a control voltage is supplied to the reel motor.
- ○ The output data controls the direction of the current fed to the reel motor.
- ○ Short REW/FF
- ○ The output data causes the current to flow in the reverse direction at the beginning of eject and during unloading. When the start sensor is ON, it will allow the motor to fast forward the tape for a short period until the leader tape passes.
- ○ The output data allows the voltage applied to the reel motor to gradually decrease when the counter reaches ±100 during the Counter Search mode.
- ○ Except during the search mode, the output data allows the control signal from the SERVO circuit board to be cut off.

1) When the FF or REWIND button is depressed (except during Search), pin-7 of expander IC4 becomes from High to Low. This causes pin-10 of IC12 to become High and a curved voltage determined by the charge of C4 will be fed to the base of Q17. And the voltage corresponding to that will be applied to E-SW.

2) The direction of the current applied to the reel motor is controlled by pins 2 and 3 of IC5. Normally pins 2 and 3 are High to turn on Q18 and Q19, thereby grounding both terminals of the reel motor.
When the reel motor is rotated in the fast forward direction, pin-3 becomes Low, thereby turning off Q13, Q11 and Q19. This allows the current output from the emitter of Q15 to flow in the following sequence: Q10 → CONN [81] → reel motor → CONN [82] → Q18 → ground, so that the reel motor is rotated in the fast forward direction.
When the reel motor is rotated in the rewind direction, pin-2 becomes Low, and unlike during fast forward, the current flows from CONN [82] to CONN [81]. During the stop and brake of the reel motor, Q17 is designed to turn OFF so as to prevent any damage to E-SW due to overload.

3) IC 4 pin 10 and IC 5 pin 2 and 3 function to control the Short FF and the REW. When IC 4 pin 10 is high, the REEL MOTOR is rotated in the controlled direction by means of IC 5 pin 2 and 3.
The IC 4 pin 9 which is a control terminal of the IDLER becomes high when it transfers the IDLER.

4) When the counter becomes "0000" ± 100 at the time of SEARCH, IC 4 pin 8 is cut off and the TU REEL FG PULSE is impressed on IC 10 pin 7. Then IC 11 pin 10 becomes low because of periodic movement of the FG PULSE and since C4 discharges at this time, the voltage added to the Q17 base gradually decreases to the voltage inversely proportional to the TU REEL rotation, thereby preventing the overrun during the stop mode.

5) During the Search mode, the error voltage is supplied from the SERVO circuit board. This error voltage is controlled by whether a signal is fed to the base of Q17 from pin-5 of IC5 or not. Pin-5 of IC5 is normally High and becomes Low only during the Search mode.

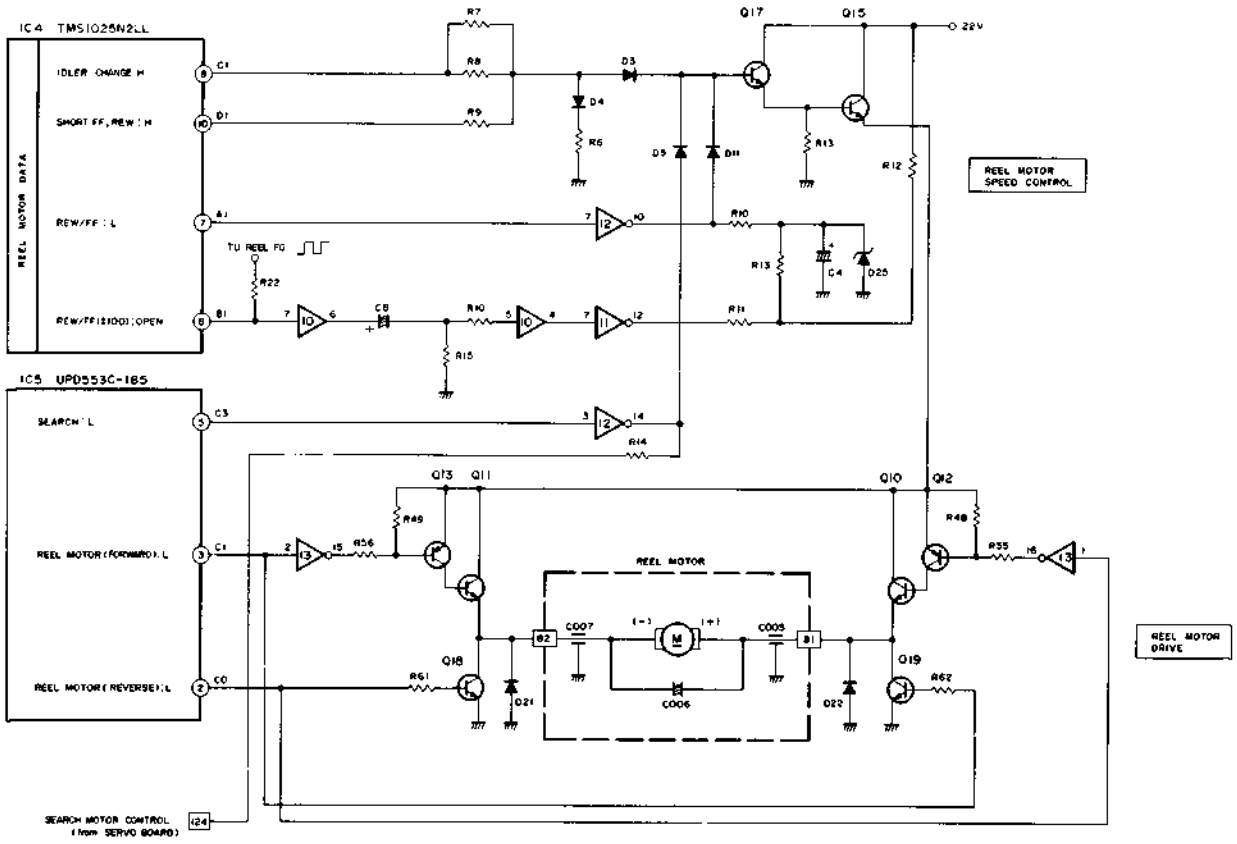

Fig. 3-2 Reel motor control circuit

2. POWER ON/OFF CONTROL CIRCUIT

A 10 bit serial code is used for power on/off control of the HR-7600. Since this functions does not appear in earlier models, a brief outline is given below.

The main control functions performed by this circuit are as follows.

1) Provided that the rear panel main power switch is on, this circuit operates when the front panel power switch is set from off to on.
2) When the front panel power switch is on, remote power switch operation becomes enabled.
3) After completion of loading, when the power switch is set to off, unloading is first performed, then the power is cut off.
4) If the power switch is set to off during the eject operation, the operation continues to completion, then the power becomes cut off.
5) Power on/off operation is inhibited while an operating button of the front panel or infrared remote control unit is pressed.

Front Panel Power Switch

When the power switch of the front operation board is set from off to on, Q1 switches on to short pins 8 and 9 of IC11 (M50115AP). The 10 bit serial code is sent from pin 17 to the mechacon circuit in approximately 25 msec.

Power on : 100 101 0000
Power off : 100 010 1000

This 10 bit serial code goes via mechacon board terminal 17 to the infrared receiver circuit at IC1 (M51014) pin 12. IC1 selects the signal from either the infrared remote control unit or the operation board and sends it to pin 16 of IC2 (M50127AP).

IC2 is a serial to parallel decoder and converts the 10 bit serial code to an 8 bit parallel code. Although the CPU controls the mainframe in accordance with these parallel data, power on/off is controlled by the flip-flop output from IC2 pin 11. After inverting at Q20, the flip-flop signal goes via connector 2 to connector 32 of the T/T board.

The power on signal is supplied to timer control CPU IC206 pin 35 and becomes obtained as a high level signal from pin 24. This signal goes through inverter IC208 pins 7 and 10, then via connector 43 to connector 53 of the power supply board. Low at connector 53 switches power on and high switches power off.

At the same time, the power on/off signal from the mechacon circuit is supplied via the servo board to connector 81 of the power supply board. The purpose of this is to maintain power in event the power switch is set to off while the eject or unloading mode is in progress.

If power is set to off during eject, high potential from IC5 pin 31 becomes inverted at IC12 pins 5 and 12 and goes as low from mechacon connector 127 to power supply board connector 81 to maintain the power on state. Thus, even though high appears at connector 53, the low at connector 81 maintains power on until the completion of eject.

Similarly, connector 81 potential maintains power on during loading until the loading arm reaches the completely stopped state.

During loading or play (loading complete) modes, the power switch off sends the 10 bit serial code to IC2 (M50127AP), which detects the power off state. Low from flip-flop output IC2 pin 11 goes through inverter Q20, and appears as a high level signal at IC3 pin 9.

From this high, the mechacon CPU detects the power switch off state and issues the stop mode instruction to the mainframe. The loading motor turns to begin unloading. While the loading arm is in the loading state, high appears at CPU IC5 pin 31. This signal maintains power on during loading and becomes low when the loading arm reaches the stop state.

Since the power switch is electronically controlled, observe the following points during service.

① Check for presence of the 10 bit serial code during power on/off operation. For example, if another switch is held depressed due to faulty front panel installation, the power switch becomes inoperative.

② Observe that mechacon IC2 pin 11 changes between low and high states with power on/off operation.

③ Check IC206 of the T/T board. Power on/off for both timer recording and normal operation is controlled by the same circuit via T/T board IC206. Therefore, it is important to check IC206 operation.

During service, inadvertently touching the clock oscillator (pins 1 and 42) by hand can stop the CPU operation. Even with the power cord disconnected, the approximately 10 minute period of the back up capacitor can prevent IC206 reset. Therefore, in this event, disconnect the power cord and short the leads of the back up capacitor.

④ Check CP-1 of the T/T board. This is an IC protector fuse which opens when current flow exceeds 1 A. Therefore, in event of a short occuring in the tuner/timer circuit, be sure to check CP-1.

3.1.2 Infrared remote control unit

As the operation control on the main unit duplicates that of the infrared remote control unit in principle, the description that is given centers on the infrared remote control unit.

Infrared remote control unit

The infrared remote control as adopted for the HR-7600 is a beam remote control using infrared rays whose wavelength is on the order of 950 mm.

The remote control transmitter uses an LED (near infrared light emitting diode) and the receiver (main unit) uses a photodiode. The remote control functions by intermittently emitting a frequency (40 kHz) with a certain pulse allocated for each function of the remote control.

The function of the remote control as used in the HR-7600 is described below:

1. Transmitter

The infrared rays which have been adopted for use can be referred to as near infrared rays with a wavelength of 940 nm and they show spectral characteristics of the LED used in the transmitter.

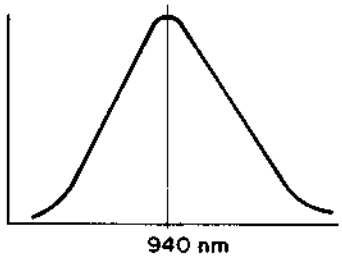

Fig. 3-3 Spectral characteristics of the LED used in the transmitter

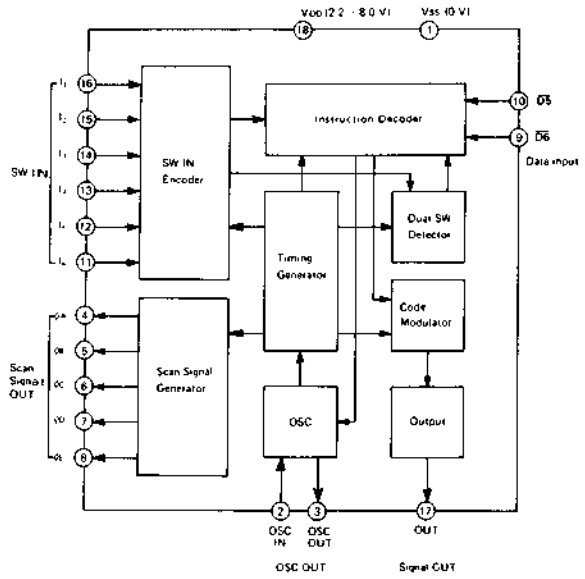

Fig. 3-4 Parallel to serial encoder (M50115AP)

The remote control transmitter employs a GaAs infrared light emitting diode.

The remote control transmitter consists of GaAs infrared light emitting diode and an IC (M50115AP) that generates the PCM signal.
The block diagram of this is shown in Fig. 3-4.

When a button on the remote control unit is pressed, a 10-bit serial code corresponding to its function is transmitted.
However, what is actually transmitted is an intermittent infrared ray signal in the form of a 10-bit pulse.

2. Transmitting signal

When a button on the remote control unit is pressed, a serial 10-bit code is emitted from the infrared LED.
This serial 10-bit code is a pulse signal generated from IC (M50115AP) inside the remote control unit. That is, when a button on the remote control unit is pressed, a 10-bit serial signal corresponding to the control function is automatically generated.

In the HR-7600, since the clock frequency of the IC on the remote control unit is set to 455 kHz, the carrier of the transmitting signal output from the IC is of 38 kHz.

That is, the output code of a 10-bit serial signal is PCM modulated. The high level of the transmitting signal is about 2.5 msec. Thus, 10 pulses of 38 kHz is a positive pulse of the transmitting signal.

Next, the distinguishing of the transmitting code (code corresponding to the control switch) between "0" and "1" is made by varying the pulse width of the transmitting signal.

As shown in Fig. 3-5 when the code is "0", the width of the transmission pulse is made about 1 msec. When the code is "1", the width is set at about 2 msec.
1 code (1 control code) of the transmission command consists of a 10-bit serial code or 11 pulses. Thus 1 period (1 control code) is transmitted within 24 msec. The transmission code of one word for a 10-bit serial control code is fed to the LED driver circuit which generates infrared rays. The first 3-bit part of the 10-bit serial code are used as a key code between the transmitter and receiver.

In the HR-7600, this key code is set to "1" "0" "0". From 4-bit onward to 10-bit, output is made corresponding to that of each control key.
For operation codes, refer to Table 3-1.

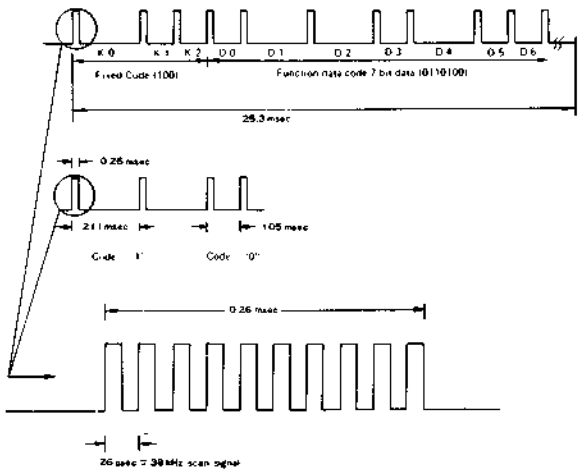

Fig. 3-5 Serial code

	D_6	D_5	D_4	D_3	D_2	D_1	D_0
Stop	0	0	0	0	0	1	1

Table 3-1

3. M50115AP

This M50115AP is a CMOS IC designed for the infrared remote control transmitter.

IC M50115AP consists of oscillating circuit, timing generator circuit, scan signal generating circuit, key-in encoder, instruction decoder and multiplex key decision circuit. This IC has a maximum of 6 x 5 key matrix inputs and 2-bit independent data inputs or a total of a 10-bit PCM (Pulse code modulation) code and is capable of transmitting a maximum of 124 sets of commands. Moreover, this IC stops oscillating except during key input (while a key is being depressed) to decrease power dissipation.

OSC circuit

Since this IC incorporates CMOS inverter and high ohmic resistors for biasing, connecting ceramic resonators to pins 2 and 3 forms an oscillating circuit.

By setting an oscillating frequency at 455 kHz, the carrier of the transmitting signal is made 38 kHz.

Also the oscillating circuit is disengaged except during key operation.

4. Infrared receiver

A 10-bit serial operation code by infrared rays transmitted from the remote control unit is received by the photodiode at the infrared ray receiving window situated to the right of center below of the operating panel on front of the HR-7600.

This photodiode is one specially made for the infrared remote control unit with a larger area than usual to be illuminated and having a higher sensitivity.

The spectral characteristics are shown in Fig. 3-6.

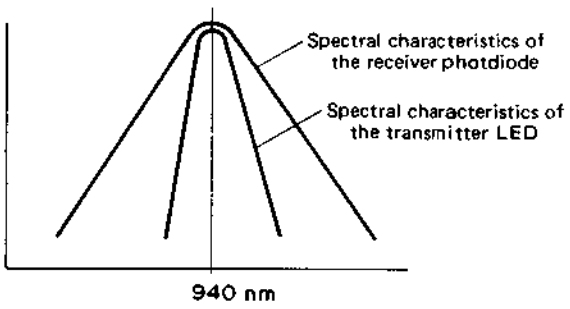

Fig. 3-6 Characteristics of infrared receiver

The transmission code corresponding to the operation key on the remote control unit is emitted in near infrared rays, which in turn is received by the photodiode installed on the MECHA-CON circuit board.

During infrared radiation, a minute current flows through the photodiode and an input signal voltage can be obtained corresponding to the rays (photoelectric conversion).

This input signal is amplified by pre-amp IC1 and passed through the filter (38 kHz or thereabouts) and the waveform-shaping circuit, and then fed to pin 16 of IC2 as a 10-bit serial PCM signal.

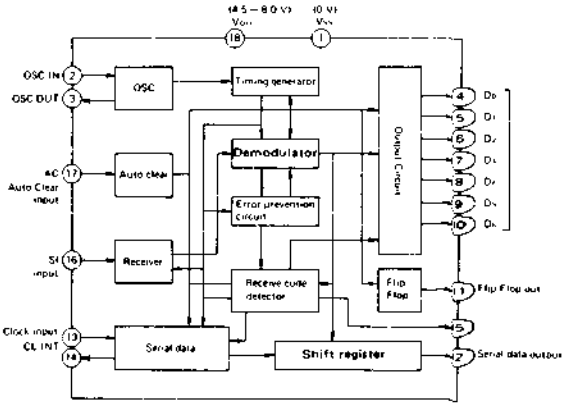

Fig. 3-7 Serial to parallel decoder

3.1.3 Serial-to-parallel decoder

In the HR-7600 when a Function button on the main unit is pressed, the information is encoded into the operation code (10-bit serial signal) by the function button code generator IC1 (M50115AP) on the operation PCB and fed to pin-12 of IC1 on the MECHA-CON circuit board. The signal amplified here is inputted to pin-16 of IC2 (M50127AP) serial-to-parallel decoder and fed to IC3 (TMS1025N2LL) input expander as an 8-bit parallel signal. Likewise, the signal from the wireless remote control unit is sent to IC2 and decoded into 8-bit parallel signal.

The serial-to-parallel decoder (M50127AP) is a specially manufactured IC for the infrared remote control receiving system and consists of oscillating circuit, timing generator circuit, demodulating circuit, malfunction prevention circuit, receiving state decision circuit, serial data processing circuit, shift register, receiving input circuit, and auto-clear circuit. This IC identifies the transmission signal from the receiver and is capable of remotely controlling 120 operations.

(1) Receiving input circuit and demodulating circuit

The operation code is inputted to $\overline{SI}$ and processed in the input circuit and then fed to the demodulating circuit, where the pulse width of the pulse signal is judged and the pulse signal is converted into the digital code. The relationship between the $\overline{SI}$ input waveform, code and data is shown in Fig. 3-8.

T between 0.4 msec and 1.6 msec yields code "0", data "L".
T between 1.6 msec and 3.2 msec yields code "1", data "H".

Fig. 3-8 Serial code demodulator

When the width of the input pulse of the $\overline{SI}$ input exceeds 3.2 msec., one word is judged to have terminated at this point. When the width goes beyond about 50 msec., the transmission command is judged to have finished and each output goes into a standby mode. In the standby mode, data output $D_0 \sim D_6$ and 1R become Low.

(2) Malfunction prevention circuit

The signal whose duration of "L" of $\overline{SI}$ input is below 50—100 μsec cannot be accepted as a transmission signal. Also when Tp or pulse width is below 0.4 msec., the unit re-enters the Standby mode to prevent any malfunction. Furthermore, when the input codes are all "0" or "1", the unit re-enters the Standby mode.

(3) Receiving state decision circuit

If the same transmission code is continuously received more than once, IR or the receiving state display output becomes High.

(4) Received code and data output

Data output $D_0 \sim D_6$ correspond with the transmission code $D_0 \sim D_6$. When the code is "0", the data output will be "L". When the code is "1", the data output will become "H". The FF or the output of the flip-flop will become "H" when the transmission code $D_0 \sim D_6$ is "1010000" and become "L" when the transmission code $D_0 \sim D_6$ is "0101000". In this unit, this code is allocated for ON/OFF of the power.

(5) Serial data processing circuit

After about 6.25 μsec. from the time when the same code is received twice (that is, when IR output goes from "L" to "H"), the input output goes from "L" to "H". If a clock pulse is inputted to CL or clock input for serial data output while the INT output is "H", the transmission code then received will be outputted to SD serial data output in the order of $D_0 \sim D_6$ synchronizing with the rise edge of CL input. Therefore, if the state of SD output is judged by the fall edge of the CL input, the content of the transmission code can be read. (Refer to the timing diagram.) The SD output is of a 3-state construction. During the Standby mode, it is disable (presenting a high impedance). After the INT output becomes "H", the disable state is released during the fall edge of the first CL input. After that,

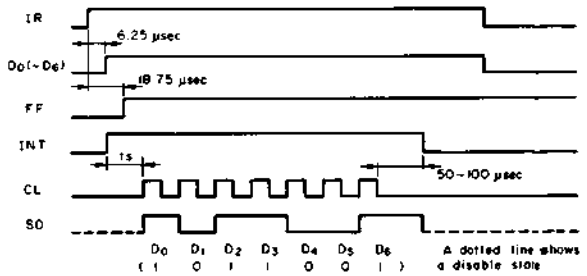

Fig. 3-9 Timing of senial to decorder

the serial data $D_0 \sim D_6$ is outputted. Once the INT output becomes "L", the SD output will be disable again. (The pull-down resistor is incorporated in the CL input.)

3.1.4 Tape-end detection function

A front-loading design has been adopted for the HR-7600, the cassette is enclosed inside the main unit so that the tape condition cannot be observed during recording and playback.

Therefore, in the HR-7600 when the tape nears its end during recording and playback and about 10 minutes of tape remains, a tape-end LED indicator on the left upper side of the front panel comes on and starts flickering 5 minutes before the end of the tape to inform the user that just less than 5 minutes of tape remains.

This function is referred to as the tape-end detection function. The detection of the tape-end is controlled by the microcomputer on the servo PWB.

The detection of the tape-end can be made by measuring the rotation time of the disks on the take-up and supply reel.

The reel disk as used in the HR-7600 comprises a combination of wheel with 48 teeth and a photo sensor; a single revolution of the wheel generates 48 pulses. By measuring the time for counting 48 pulses of both the take-up and supply reel disks, the time required for a revolution of each reel disk can be obtained.

By detecting the amount of time both reel disks to take for a single revolution, the type of the cassette can be determined: That is, either thick-hub reel (T20, T60) or a thin-hub reel (T90, T120). After the type of cassette has been determined, measuring the time required for a rotation of the supply reel disk allows the detection of the remaining tape.

NOTE: As the tape speed is constant, the following equation can be given:

(Number of pulses of supply reel FG)^2 + (Number of pulses of take-up reel FG)^2 = constant

Also, by seeking a mean value of the number of pulses of supply and take-up reels, the type of tape can be known.

3.1.5 Various operations by the mechanism controller

Here, various operations controlled by the mechanism controller are described.

1. POWER ON

Power ON means a condition where the sub-power indicator on the front panel is lighted. In this condition, all the operations including the loading/unloading of the cassette for the first time are possible.

The POWER-ON condition requires that the AC switch (on the rear panel) be turned ON and,

(1) Set the sub-power switch on the front panel to ON. When it is already set to ON, set it to either the OFF or TIMER position to clear once then set it to ON again. Or perform the power-on operation via the remote control unit.

(2) The sub-power switch is in the TIMER position and the timer reaches the preset time range.

The first operation after power is ON (the power-on in the Timer mode will be discussed later) is . . .

(1) When a cassette is not loaded in the HR-7600, the cassette housing motor rotates in the eject direction for 1–2 sec. then stops. The mode indicators will all be off.

(2) When a cassette is loaded in the HR-7600:
   1) The HR-7600 will go into the eject mode when the cassette does not press the cassette switch.
   2) When the cassette presses the cassette switch,
      a. When the tape is unloaded, the HR-7600 will go into the Stop mode after applying a low voltage to the cassette housing motor for about 1 sec. in the direction of IN.
      b. When the tape is not in the unloading state, the HR-7600 will go into the Unloading mode.

2. POWER OFF

Power OFF means a condition where the sub-power indicator on the front panel is not lighted. In this condition, all the operations including the loading/unloading of the cassette are impossible.

In order to turn off the power,

(1) Turn the MAINS POWER switch (on the rear panel) to OFF. In this case, even if the MAINS POWER switch is turned ON again, the HR-7600 will not turn on unless it is in the Timer mode. However, when the MAINS POWER switch is turned off for an extremely short period of time, the previous state will be maintained.

(2) Set the sub-power switch on the front panel to OFF. During loading, unloading and eject operations, power will be turned off after completion of the respective operation. (Loading will change to unloading.)

(3) When the program timer is not within the preset time range, set the sub-power switch to the TIMER position. When set to the TIMER position during recording (except in the Pause mode), the HR-7600 will go into the Sleep mode and continue recording and will not be turned off.

(4) Turn the power OFF via the remote control unit. During loading, unloading and eject operations, power will be turned off after completion of the respective operation.

3. General controls

For mode changes, refer to the mode change table.

Control operations on the main unit have priority over all operations on the remote control unit including power ON/OFF. The order of priority is 1) control operations on the main unit, 2) wireless remote control operations, and 3) wired remote control operations. The camera remote control operations will have the same in priority as button operations on the main unit. There is no order of priority among the control buttons; when two or more buttons are pressed simultaneously, their intended operation will become void. However, an exception is that the REC and AUDIO DUB buttons will be valid when they are pressed simultaneously with the PLAY or STILL/PAUSE button.

Control operations via the wired remote control unit have an order of priority:

When two or more are pressed at the same time the one having the highest priority will become valid.

4. Operations that are performed automatically

(1) Automatic STOP

1) When the tape is fully rewound in the rewind mode;
   - ○ When the leader portion of the tape is detected, the tape is wound in the forward direction until the leader portion passes the detector, then stopped.
2) When the tape counter reaches "0000" in the Counter Search mode with the mode set to FF or REW.
   - ○ In this case, the counter should read "0000" without fail in the Stop mode when an E-30 tape is used.
3) When the tape is fast-forwarded or rewound in the Cue Search mode;
   - ○ When the cue signal is detected, the automatic stop will be engaged.
4) When the tape is left for 5 to 7 minutes continously in the Still/Pause or Slow mode.
5) When the supply reel does not rotate within about 7 seconds in the Fast forward mode.
6) When the take-up reel does not rotate within about 7 seconds in the Rewind mode.
7) When the take-up reel does not rotate within about 2 seconds in the Play mode (does not apply to Still/Pause, Slow and Search modes).
8) When the drum does not rotate within about 3 seconds after the loading switch is ON.
9) When the tape loading has not finished within about 6 seconds after entering the Play mode.
10) When power to the video recorder is turned off.

(2) Automatic EJECT

1) When the end of the tape is reached in the Timer Record mode.
2) When the tape-end detection lamp is burned out.
3) When the cassette switch has not been pressed even after a cassette has been loaded for about 6 seconds.
4) When the beginning- and end-of-tape detection mechanisms are both turned on simultaneously (when light enters both).
5) When the cassette switch is turned off (by pressing) from the ON (position).
6) When a cassette with its tab removed is loaded in the Timer Recording mode.

(3) Automatic REWINDING

When the end of the tape is reached in all modes except the Timer mode.

(4) Automatic Still/Pause

In the Timer mode, when the timer has reached 10 seconds prior to the preset time for timer recording to begin.

(5) Automatic stopping of all drive mechanisms

1) When the unloading operation has not finished within about 6 seconds after entering the Unloading mode.
   - ○ In this case, the indicator continues flickering as previously engaged while all the drive mechanisms are stopped except the capstan motor and drum motor. At this point, all the controls will be disabled also.
2) When the eject operation has not finished within about 6 seconds after entering the Unloading mode.
   - ○ In this case, the EJECT indicator continues flickering whereas all the drive mechanisms are stopped. At this point, all the controls will be disabled also.

5. TIMER mode

(1) Basics regarding the Timer mode

1) When the video recorder is set to the Timer mode, all the controls will be disabled.
2) In principle, when the video recorder is in the timer mode it will enter the Recording mode at the preset time. However, when a cassette with its tab removed is used, the video recorder will enter the Eject mode when set to TIMER.

	STOP	PLAY	STILL/ PAUSE	SLOW	X 2	FRAME ADV.	S. FF	S. REW	FF	REW	REC PLAY	REC PAUSE	A. DUB PLAY	A. DUB PAUSE	PAUSE

EJECT UN-LOADING	×	×	×	×	×	×	×	×	×	×	×	×	×	×	×

Table 3-2 Mode shift table

3) The power will continuously be applied in the Timer mode as long as the program timer is within the range of preset time.
   - ○ Normally power is turned on 10 seconds prior to the preset time and the video recorder stands by in the Pause mode for 10 seconds. When the tape reaches its end, the video recorder will eject the cassette automatically. At this point if another cassette is loaded, the video recorder will automatically enter the Recording mode.

(2) The first operation after POWER ON

1) When a cassette is not loaded;
   - ○ The cassette housing motor rotates for 1 to 2 seconds in the direction of Eject, then stops. At this point, all the mode indicators will be off. In this state, if a cassette is loaded, the video recorder will automatically enter the Recording mode.

2) When a cassette is loaded;

i) When a cassette does not press the cassette switch; The video recorder will enter the Eject mode.

ii) When the cassette presses the cassettes witch;

a) With the tape in the unloading state
   - ○ After a low voltage is applied to the cassette housing motor in the direction of IN for about 1 second, the video recorder will enter the REC-PAUSE mode.

b) With the tape not in the unloadings tate
   - ○ The VTR will go into the REC-PAUSE mode.

c) With the tape wound to its end
   - ○ This state supersedes a) and b) above, and the video recorder will enter the Eject mode.

6. Camera pause

(1) The camera pause is engaged only when the REC SELECT switch is set to the CAMERA position in the REC mode.

(2) When the pause operation is made initiated via the camera, the video recorder will go into the REC-PAUSE mode if operating in the REC mode. Once set to this state, no controls on the main unit will put the video recorder into the REC-PLAY mode again.

(3) When the REC-PLAY operation is entered from the REC-PAUSE mode via the main unit control, first set the camera's pause control switch to the PAUSE (STOP) position, then back to the PLAY (START) position in order to obtain full camera control over the video recorder.

(4) When the camera pause control switch is at the PLAY (START) position, the main unit controls will not be restricted at all.

3.1.6 Check points regarding the mechanism controls

1. POWER ON-1

Make sure that the unit will not be turned ON even if the MAINS POWER switch on the rear panel is flipped from OFF to ON. Make sure that the sub-power indicator will not come on even if the on/off operation of the MAINS POWER switch is repeated 4 times with the sub-power switch on the front panel set to ON.

2. POWER ON-2

Make sure that the POWER ON operation functions every time. Make sure that the sub-power indicator lights without fail every time the on/off operation of the sub-power switch is repeated 4 times with the MAINS POWER switch ON.

3. Initial operation

Be sure that the cassette is positioned correctly after power is switched and the cassette is loaded.

Without loading a cassette, but with the cassette switch pressed turn the unit on and off. At this point, make sure that the cassette housing motor rotates momentarily in the direction of loading.

4. Operation switches

Make sure that each control switch operates without fail and that each indicator lights properly.

Confirm by referring to the mode change table (Table 3-3).

5. Tape-end sensors

Make certain that both the tape-end sensors operate without fail at both ends of the tape.

Check it in the FF and REW modes.

FF: Auto rewinding at the tape's end

REW: Auto stop at the tape's end

6. Auto stop-1

When the rotation of the reel stops in the either fast forward or rewind mode, the video recorder should enter the Stop mode automatically. Enter fast forward or Rewind without loading a cassette while pressing the cassette switch. Check if the video recorder automatically enters the Stop mode in about 7 seconds for both FF and REW modes respectively. At this point, be sure to cover both tape-end sensors.

7. Auto stop-2

When the rotation of the take-up reel stops in the Play mode, the video recorder should enter the Stop mode automatically. Enter Play without loading a cassette while pressing the cassette switch. Check if the video recorder automatically enters the Stop mode in about 2 seconds when the rotation of the take-up reel is manually stopped after the loading operation has finished.

8. Auto stop-3

When the rotation of the head drum stops in the Play mode, the video recorder should enter the Stop mode automatically.

Enter Play without loading a cassette while pressing the cassette switch. At this point, check if the video recorder automatically enters the Stop mode when the rotation of the head drum is manually stopped, see if the Play mode is cleared in about 3 seconds and the head drum starts rotating when it is released.

9. Auto stop-4

Make sure that the video recorder automatically enters the Stop mode in 5 to 7 minutes after being left in the Still mode.

10. Auto stop-5

Make sure that the video recorder automatically enters the Stop mode at the detection of a cue signal when fast-forwarding or rewinding in the Cue-search mode. Check in both directions – FF and REW – using the cassette tape on which a cue signal has been recorded. Make sure that auto stop does not function when the Cue-search is OFF.

11. Auto stop-6

The video recorder should automatically enter the Stop mode when the counter reaches "0000" while fast-forwarding or rewinding in the Counter-search mode. Make sure that the video recorder stops when the counter reads "0000" using an E-30 tape when the unit is made to enter the Rewind mode starting from a counter reading of 200 or more. Also make sure that auto stop does not function when the Counter-search is OFF.

12. Fast-forwarding and rewinding duration

At normal temperature an E-180 tape should take less than 4 minutes 30 seconds to rewind. Calculate the duration after confirming that the video recorder is not in the Counter-search or Cue-search mode. Also it is not necessary to choose between fast forwarding and rewinding; either will do.

13. Detection of an unrecordable cassette

The video recorder should be able to properly detect if the loaded cassette is recordable or not.

Make sure that the video recorder does not enter the Recording mode with a cassette whose erasure prevention tab has been removed. Check that the VTR does enter the Recording mode when a cassette with its tab intact is used. At this point, check to see if the Recording mode is not cleared even if the area surrounding the SLOW button on the front control panel is pressed.

14. Tape counter

The tape counter should function properly.

Load the cassette, then check to see if the counter counts up in the FF mode and counts down in the REW mode.

15. Tape-end indicator

The tape-end indicator should function properly.

Using a pre-recprded tape, check to see if the tape-end indicator flickers when the tape nears its end.

16. Remote control operation

Button controls on the main unit have priority over those on the remote control unit.

First press the FF button on the remote control unit (the video recorder enters the FF mode). Make sure that the video recorder enters only the Rewind mode while the REW button on the main unit is being pressed and while keeping the FF button on the remote control unit pressed.

17. Timer operation-1

Make sure that with the program timer the video recorder enters the REC-PAUSE mode 10 seconds prior to the preset interval of time, and goes into the recording mode when the timer reaches the preset time.

18. Camera Pause

Make sure that the switching operation between the REC and REC-PAUSE mode with the camera connector functions properly when set to the REC mode.

19. Wired remote control

Make sure that the wired remote control functions properly when connected to the wired remote control jack on the rear panel.

20. Remote control sensitivity

Directly-in-front operation . . . . . Approx. 15 m
±30°-to-either-side operation . . . . . Approx. 10 m
±45°-to-either-side operation . . . . . Approx. 3 m

Measure the distance by directing the transmitter towards the main unit with nothing within a 2 m vicinity of the video recorder. At this point, care should be taken so that no strong light source such as fluorescent lamp, etc. is directed toward the main unit.

21. Error in the tape-end indication

Make sure that the error in the tape-end indicattion is within −30 seconds to +300 seconds.

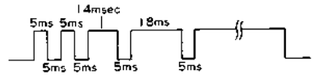

Fig. 1

3-11

3.2 SERVO CIRCUIT

3.2.1 General description

In the context by which they are used in video tape recording equipment, servos can be defined as systems for automatically controlling mechanical quantities, such as rotational speed and phase, by detecting errors from the normal values and converting the error values into compensating feedback signals.

For servo systems are used in this model: 1) drum servo, which controls the speed and phase of the rotating video heads, 2) capstan servo, for controlling tape transport speed and phase, 3) reel servo, which controls the tape speed during search FF and search REW operation, and 4) back tension servo, for regulating tape back tension. Of these, the back tension servo operation is entirely mechanical. Therefore, only the drum, capstan and reel servo systems are outlined in this section.

Precision control is required for the drum and capstan systems, necessitating servo control of both speed and phase. Such high precision is not required during search FF/REW and thus only speed control is performed by the reel servo system.

Speed servo detects the speed error of the object (motor, etc.) to be controlled and converts the error value into a feedback signal. Phase servo requires a reference signal. The phases of the reference signal and the object to be controlled are compared to yield the error value, which is then used for feedback. Thus, when analyzing servo systems, it is necessary to first determine the reference and comparison signals for each operating mode.

Since the reel servo operates only during search FF/REW, the following description is centered on the drum and capstan servo systems.

3.2.2 Drum servo circuit

1. Purpose

The drum servo circuit controls the speed and phase of the head drum during recording and playback. Two control circuits are used independently for control of speed and phase.

Speed control circuit (discriminator):

Utilizing the FG signal produced by the drum motor, this circuit detects speed and compensates for variations.

Phase control circuit:

Utilizing the drum pulse produced by the magnet which is attached to the rotor of the motor, this circuit detects the phase of the rotating drum and corrects it. During recording, it detects the vertical sync signal of the video signal to be recorded and the phase of the drum pulse, thereby controlling the rotating phase of the head drum. In this way, the position of the video signal on the tape is controlled. During playback, the playback picture is stabilized by the head drum whose rotation is locked to the frequency of a quartz oscillator.

Table 3-3 summarizes the reference and comparison signals for controlling the speed and phase of the rotating head drum during recording and playback.

2. Signal flow during recording

1) Reference signal

The reference signal is taken from the vertical synchronization (V. sync) component of the video signal to be recorded. Composite sync from the Y & PRE/REC board is applied via connector 31 to a lowpass filter (LPF), which passes only the vertical sync component. At IC7 pin 23, a monostable multivibrator counts the signal down to 25 (30) Hz for triggering the next stage recording phase monostable. The output of the REC phase monostable then goes as the sampling signal to the sample & hold circuit.

MODE	DRUM SERVO		CAPSTAN SERVO	
	REFERENCE	COMPARISON	REFERENCE	COMPARISON
REC	VIDEO V. SYNC	DRUM PICK-UP PULSE	X'TAL OSC.	CAP. FG
PLAY BACK	X'TAL OSC		X'TAL OSC.	CONTROL PULSE
ASSEMBLY EDIT	VIDEO V. SYNC		VIDEO V. SYNC	CONTROL PULSE ↓ CAP. FG
INSERT EDIT	VIDEO V. SYNC		VIDEO V. SYNC	CONTROL PULSE
SEARCH	DISCRIMINATOR			
SLOW	X'TAL OSC	DRUM PICK-UP PULSE	PULSE DRIVE	

Table 3-3 Servo signal

3-12

The time constant of the REC phase monostable determines the position for recording the vertical sync signal on the tape. During recording, R73 adjusts the video head switching position.

2) Comparison signal

The comparison signal is obtained from the drum pulse, which corresponds to the video head rotational phase. Two magnets are embedded in the rotor of the drum motor and, as the drum rotates, a pickup head detects the magnets and produces the drum pulse.

R56 adjusts the level of the drum pulse supplied to pin 3 of IC7. The switching phase monostable compensates for small errors between the mounting positions of the magnets and video heads.

In the CCIR setting, the 70° delay monostable delays the signal by the angle difference with respect to the NTSC (30 Hz) setting.

The compensated drum pulse is converted into a square-wave with a 50% duty cycle by a flipflop circuit, then sent via the trapezoid circuit to the sample & hold circuit.

3) Phase error

At the sample & hold circuit, the phases of the reference signal from the recording phase monostable and the comparison signal from the trapezoid circuit are compared, yielding an error voltage which is held by C40. The error voltage goes from IC7 pin 14 to the loop filter and limiter. The loop filter serves to attenuate high frequency components in the error voltage, thereby avoiding irregular motor rotation and jitter. The limiter suppresses the error voltage to within a certain range to prevent abnormal rotation of the drum motor.

From the loop filter, the error voltage is sent through a voltage-follower to the non-invert input of the mixer. A DC voltage proportional to the error voltage is then obtained from the mixer output.

The error voltage from the discriminator circuit is applied to the invert input of the mixer. However, during recording, the drum motor rotation is essentially fixed, and thus the potential at the non-invert input can be considered fixed.

The mixer output is supplied to pin 1 of IC14, which controls drum motor rotation. Via pin 1, the error voltage goes through the input gain control, rectifier and control amplifier to the rotation control circuit.

At the rotation control circuit, the switching pulse from the Hall circuit is applied to pins 4, 5, 16 and 17. This pulse is used for controlling the direction of current flow in the motor coils.

4) Motor construction

As shown in Fig. 3-11, the motor is composed of an outer rotor and a stationary coil wound stator. Current flow in the coils produces a rotating magnetic field, which drives the rotor.

Hall elements detect the rotor position and regulate the current flow in the coils, and consequently the rotational speed. This system is also capable of applying reverse (braking) torque, thus reducing the time needed to attain synchronous rotation.

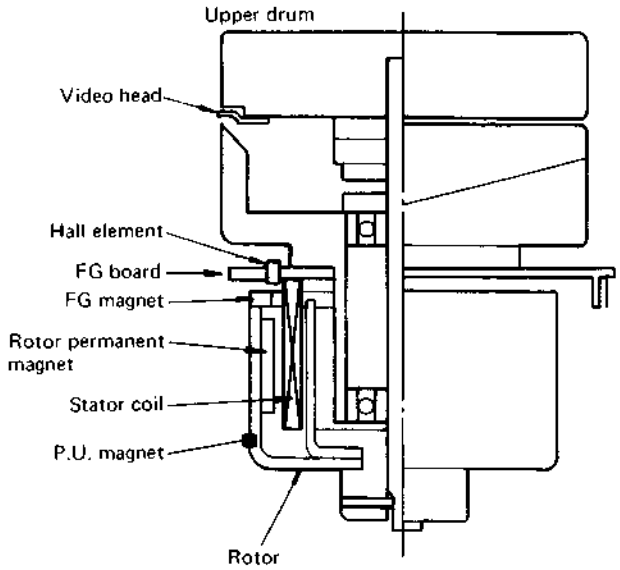

Fig. 3-11 Drum assembly

Hall element

In certain semiconductors, when a current (IC) flows perpendicular to a magnetic flux (b), a voltage (VH) becomes produced that is perpendicular (3 dimensionnally) to both the current and the magnetic flux. This relationship can be expressed as follows.

$$VH = RH \times \frac{IC \times B}{d}$$

In the above, RH is the Hall coefficient and d is the material thickness.

R_H : material constant (Hall coefficient)
d : conductor thickness

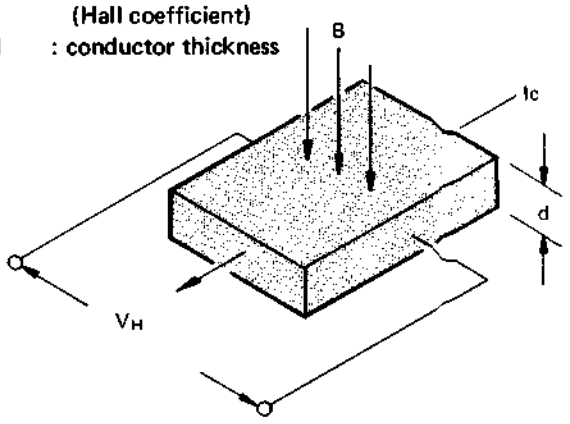

Fig. 3-12 Hall element

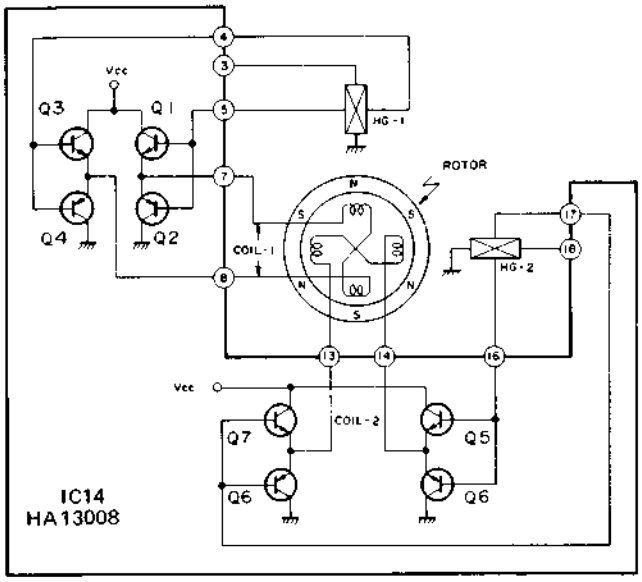
5) Motor circuit description
IC14 is illustrated in Fig. 3-13.



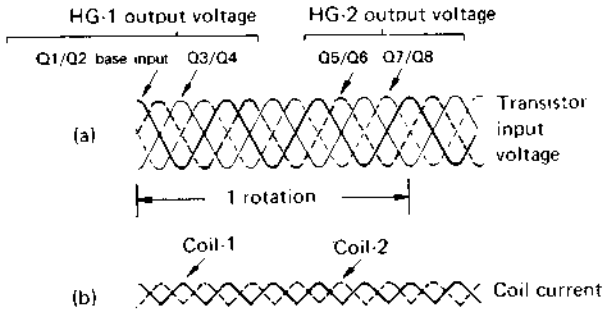


Fig. 3-13 Basic operating principle

Coils 1 & 2 and Hall elements HG1 and HG2 are mounted in the stator in the relationships indicated in Fig. 3-12. In the rotor, magnets are mounted with N and S poles alternating every 60°. As the rotor turns, the Hall elements detect the relative positions between the magnets and coils.

In the Fig. 3-13 example, a rotor N pole is adjacent to HG1, producing a positive voltage at the left output and a negative voltage at the right output of the Hall element. Q1 and Q4 switch on, while Q2 and Q3 switch off. Current from Vcc then flows in Q1, Coil-1 and Q4, and the rotor turns clockwise from the magnetic field produced in Coil-1.

As the N pole recedes from HG1, the voltage of HG1 ceases. But as the rotor rotation nears 60°, the S pole approaches HG2 and a positive voltage appears at the upper terminals and a negative voltage at the lower terminal of HG2. Q7 and Q6 switch on, and current flows from Vcc to Q7, Coil-2 and Q6. The rotor continues to turn from Coil-2 magnetic field. When an S pole reaches HG1, Q2 and Q3 switch on. Current flows in the opposite direction through Coil-1 and clockwise rotation continues. In this manner, sequential switching is performed and the rotor turns continuously in a fixed direction.

Speed and phase are controlled by voltages from the speed and phase servo circuits combined with Vcc. Switches are provided between the Hall elements and transistors that can apply the voltages from the Hall elements oppositely, producing a braking effect as current flows in reverse direction in the coils.

6) Drum speed control
Drum motor control signal from the mechanism board goes via connector 7 of the SERVO and D31 to IC14 pin 20. Low voltage (less than 2 V) is supplied to pin 20 of IC14 and the drum motor does not rotates. The motor current is proportional to the input voltage. High voltage (more than 7 V) is supplied to pin 20 of IC14 and the drum motor rotates.

The rotation of the drum motor automatically changes from forward to reverse, when the input voltage from IC14 pin 1 exceeds 5 V.

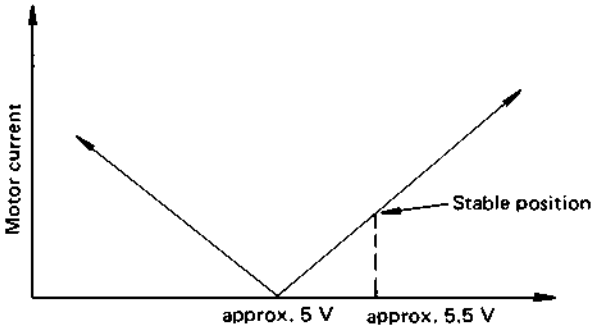

Fig. 3-14

7) Control signal
The reference signal from the 1/2 countdown monostable goes through the control delay and control duty monostables, which determine the interval between positive and negative pulses of the control signal for recording on the tape. This signal is then routed from IC7 pin 18 via the relay board to the control board.

2. Playback signal flow
An internal crystal oscillator signal is employed as the drum servo reference, while the comparison signal is the same drum pulse used for recording. The 32.768 kHz crystal oscillator frequency is counted down to 25 (30) Hz and triggers the recording phase monostable. Afterwards, signal flow is the same as during recording.

3. Speed control signal
The speed control (or discriminator) control system functions to maintain a fixed frequency during motor start-up (when frequency variation is large) and provide a dampling effect for reducing rotational irregularities. Motor rotation yields the frequency generator pulse, variations of which are converted into voltage variations, and these in turn are used for controlling motor rotation.

The FG pulse goes to the drum FG amplifier, a Schmitt circuit for shaping the waveform, then to the F-V (frequency to voltage) converter. With respect to the normal

FG frequency of 1600 (1920) Hz, an increase or decrease in frequency becomes converted into an increase or decrease in voltage.

This voltage is applied to an active filter for removing jitter, then to the invert input of the mixer. The mixer circuit amplifies and inverts the voltage, after which it is sent to IC14 pin 1. In this manner, drum motor rotation is controlled in order to yield an FG pulse frequency of 1600 (1920) Hz.

4. Search Fast Forward/Rewind

The search mode is enabled only during normal playback while the desired FF or REW button is held depressed. In this mode, the tape is transported at approximately 9 (7) times normal playback speed.

As indicated in Fig. 3-14, each video head traces 9 (7) recorded tracks. However, due to the slant azimuth recording system, each (CH-1 or CH-2) head produces an effective signal output only when it traces its corresponding track. Also, since the tracing angle differs greatly from normal speed, the playback FM waveform becomes a diamond-shaped pattern, as shown in Fig. 3-14, and noise bars appear in the picture display.

In the search mode, the head to tape relative speed changes and the resulting deviation in the horizontal sync frequency could disturb horizontal stability in the playback picture display. Since the color signal also becomes unstable, compensation is performed by changing the drum rotation rate.

Q6 switches on during search FF. The potential at IC13 pin 2 drops slightly, raising the potential at pin 1 from approximately 6 V to 6.4 V.

Conversely, Q12 switches on during search REW, slightly raising the potential at IC13 pin 2, while the potential at pin 2 drops from 6 V to approximately 5.4 V.

The error voltage output from IC13 pin 1 goes via an LPF and limiter, which suppress fluctuations, to electronic switch IC12. During the search mode, this switches from the phase error voltage to the horizontal discriminator error voltage.

From IC12 pin 8, the error voltage is sent in the same route as the phase error voltage and controls the drum motor.

5. Slow mode

In the slow mode, a fixed width pulse is obtained from IC6 pin 25 during the capstan motor start-up period. The pulse goes through D45 and R120 to IC13 pin 12. In this manner, compensation is performed for the deviation in relative head to tape speed during the capstan motor start-up period.

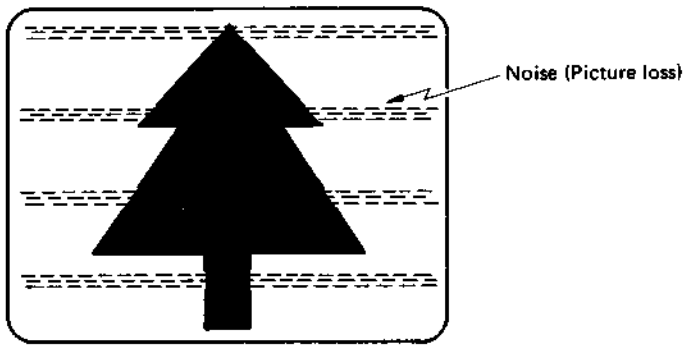
(b) Search REW mode



(c) Playback picture in Search FF/REW mode

Fig. 3-15 Search FF/REW pattern trace and playback picture

3.2.3 Capstan servo circuit

The capstan servo circuit functions to regulate the tape transport speed in order for the video heads to accurately trace the recorded signal tracks. Both speed and phase controls are employed.

1. Phase control system
The phases of the reference and comparison signals are compared to yield an error voltage which is employed for controlling the phase of motor rotation.

During recording, the FG pulse obtained from capstan flywheel rotation is divided to 25 (30) Hz and used for detecting the rotational phase of the capstan. Phase control is performed by comparing this with the phase of the 25 (30) Hz signal divided from the crystal oscillator frequency.

In the playback mode, the control signal picked up from the tape is employed. This is compared with the crystal oscillator signal and used for compensating deviations of the video heads from the recorded tracks.

2. Signal flow during recording

1) Reference signal
The reference signal is obtained from a 32,768 Hz crystal oscillator. This is counted down to 25 (30) Hz in IC7 and triggers the preset monostable, which determines the head tracing position during recording. From this circuit, the signal triggers the tracking monostable, which determines the time constant. The user-adjustable TRACKING control compensates for minor differences between prerecorded tapes during playback.

Raise and fall positions of the trapezoidal waveform are adjusted by the trapezoid duty monostable. This output goes through an inverter to the trapezoid circuit. The resulting reference signal is applied to the sample and hold circuit.

2) Comparison signal
The capstan FG pulse is employed for the comparison signal. This is sent via the relay board to servo board connectors 51 and 52. Following the AG amplifier and waveform shaping by the Schmitt circuit, the signal is counted down to 25 (30) Hz in IC7. This goes to the monostable and pulse generator circuits, then as the comparison signal to the sample and hold circuit.

3) Phase error
C27 holds the output from the sample and hold circuit, which varies in voltage with variation in phase. This is then obtained from IC7 pin 33 as the phase error voltage. In the same manner as the drum servo system, the error voltage goes through a loop filter, electronic switch and voltage follower to the non-invert input of the mixer.

At this point, the speed and phase error voltages are mixed and amplified. The mixer output is sent via an emitter-follower, which converts the impedance, and power amplifier to pins 2 and 8 of IC5. This is an interface IC which allows microprocessor control of the capstan motor forward, reverse and braking functions.

Switches SW1 and SW2 operate so that the capstan motor rotates at the speed and phase corresponding to the voltage at pin 2.

3. Playback signal flow
The reference signal is taken from the 32,768 kHz crystal oscillator and divided to 25 (30) Hz as during recording. At this time, the comparison signal is derived from the control signal played back from the tape.

From the control head, the signal goes via the relay board to the control pulse amplifier. A Schmitt circuit shapes the waveform, which is sent to IC7 pin 24, where it is inverted and triggers the control duty monostable. This output is converted to the sampling pulse by the monostable and pulse generator circuits, then supplied to the sample and hold circuit.

Afterwards, the signal path is the same as for recording.

4. Speed control signal
The FG signal obtained from capstan flywheel rotation is routed through the capstan FG amplifier, Schmitt circuit and IC7 (pins 25 and 26) to the F-V converter. In this circuit, variations in the pulse frequency are converted into variations in voltage.

During normal capstan motor rotation, the FG pulse frequency is 252.5 (360) Hz. Increase in the rotation rate yields a higher FG pulse frequency and the voltage rises. Conversely, reduced rotation produces reductions of both frequency and voltage. This error voltage output is sent to the invert input of the mixer.

3.2.4 Reel servo

The reel servo circuit controls reel motor rotation in order to regulate the tape speed during the search FF and search REW modes. In these modes, the tape is transported at 9 times (PAL & SECAM) or 7 times (NTSC) the normal playback rate.

The control head picks up the recorded control signal from the tape, which then goes via the relay board to servo board connector 41. The signal is routed through the control pulse amplifier and Schmitt circuits to IC7 pin 24. From IC7 pin 26, the control pulse is applied to the F-V converter, which yields a voltage variation corresponding to the frequency variation.

Q10 and Q11 switch on during search, increasing the amount of feedback and setting the F-V function for reel servo operation. The F-V converter output is inverted and amplified, then sent through a lowpass filter to yield the DC component from connector J4.

For subsequent operation, refer to the mechacon circuit description.

3.2.5 HR-7600 editing functions

This model includes both insert and assembly editing capabilities. A back space system is employed for both the HR-7600 whereby an approximately 1 second segment of the tape becomes automatically rewound after the PAUSE button is pressed in the editing mode.

In models without this feature, the tape simply stops at the point the PAUSE button is pressed. The recording servo disruption at this point results in a visible disturbance in the picture during playback. The back space system avoids this problem by allowing time for servo synchronization to be obtained prior to the editing point.

1) The HR-7600 is capable of both assembly and insert editing.
2) Tape rewind is performed by reversing the capstan motor.
3) The capstan frequency generator (FG) pulse is used for detecting the amount of tape rewind.
4) The overlapped segment at the edit start point is used for 5 frames.

	Assembly edit	Insert edit
Edit system	Back space edit	Back space edit
Back space	Capstan FG	Capstan FG
Back space condition	Reverse mode	Reverse mode
Double recording	First 5 frames	All insert REC
Full erase head	ON	OFF
Audio erase head	ON	ON
Audio head	ON	ON
Video head	REC Normal bias	REC 2.5 dB up
Control head	P.B. (20[25] frames) → REC	P.B.*
Capstan servo	P.B. → REC	P.B. (EXT. Lock)
Drum servo	REC	REC
Video	REC	REC
Audio	REC	Audio dubbing

Table 3-4 Assembly, insert control

* During insert editing mode, if the control signal is absent for more than 2 pulses, the recorder switches to the Rec. mode. At this time, if the control signal returns, the recorder maintains the Rec. mode.

1. Assembly editing
When the PAUSE button is pressed in the recording mode, the HR-7600 automatically enters the assembly editing mode. Picture recording stops, and the capstan motor and tape transport stop.

The capstan motor then rotates in reverse, while the CPU of the mechacon circuit counts the 25 (30) Hz capstan FG pulse. Thus, the tape travels for 1 second or 30 FG pulses (i.e., 25 [30] video frames) in reverse, after which the pause mode is entered.

At this time, by pressing the PLAY button, the play mode is first entered, during which 20 (25) capstan FG pulses are played back, then the recording mode is returned. Consequently, 5 frames become recorded overlapped.

During the 20 (25) frames playback, synchronization is established between the input video signal and the recorded control signal, thereby avoiding sync disturbance at the editing point.

The timing chart of the assembly editing is shown in Fig. 3-17.

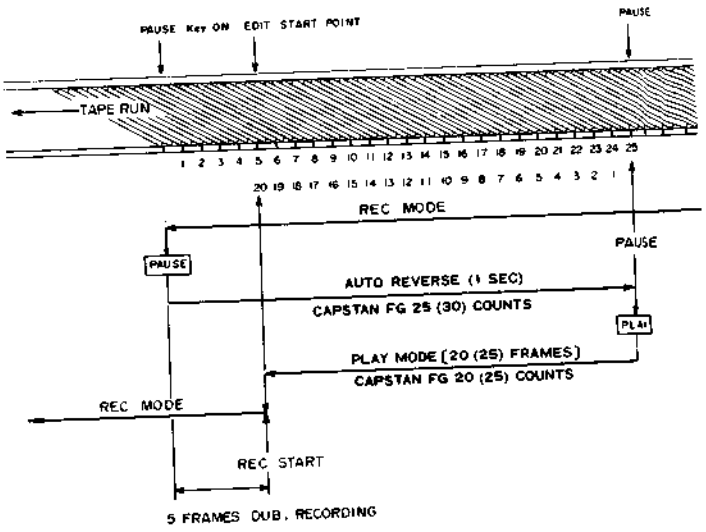


Fig. 3-16 Assembly editing

2. Insert editing
The insert editing function is basically the same as assembly editing. When the insert mode is entered, 25 (30) frames of the tape are rewound, 20 (25) frames played back, then only the video and audio heads perform recording.

① Insert editing uses a back space system.
② The capstan rotates in reverse for one second, while the 25 (30) Hz capstan FG pulse is counted (i.e., to count of 25 [30]) for controlling the back space amount.
③ In the insert editing process, 20 (25) frames are played back from the pause point, then the recording mode is entered.

④ Insert editing is performed simultaneously for the audio and video signals. It cannot be performed independently with this mode.

⑤ The audio circuit assumes the audio dub mode during insert editing. In the case of stereo versions:
Audio Channel 1 becomes set to playback.
Audio Channel 2 becomes set to recording.

⑥ The editing (recording) start point is 5 frames prior to the point the PAUSE button was pressed. The end point is at tape counter 0000 or when the STOP button is pressed.

⑦ The playback TRACKING control functions during insert editing. Insert editing can also be performed for tapes recorded on other (VHS format) machines.

⑧ During insert editing, if the control signal of the tape ceases, control signal recording automatically starts. However, even if the recorded control signal should return, this recording mode continues until completion of insert editing.

⑨ Video recording bias is increased by about 2.5 dB during insert editing.

- Insert editing allows the addition of new video and audio information to a previously recorded tape. Its main differences with respect to assembly editing are as follows.
  ① Only video recording is performed and the full erase head does not operate.
  ② When recording is performed, the servo system becomes synchronized to the control signal previously recorded on the tape.
  ③ The capstan servo circuit is in the playback status and synchronized externally (to the input video signal).
  ④ Sync disturbance is avoided at the editing start and end points.

If the tape control signal ceases, this model automatically switches to an internally generated control signal. Recording of this internal signal begins 2 frames after cessation of the tape control signal.
Afterwards, even if the tape control signal returns, it becomes disregarded and editing proceeds using the internal signal until the stop button is pushed or the tape counter reaches 0000. (See Fig. 3-18 and Fig. 3-19.)

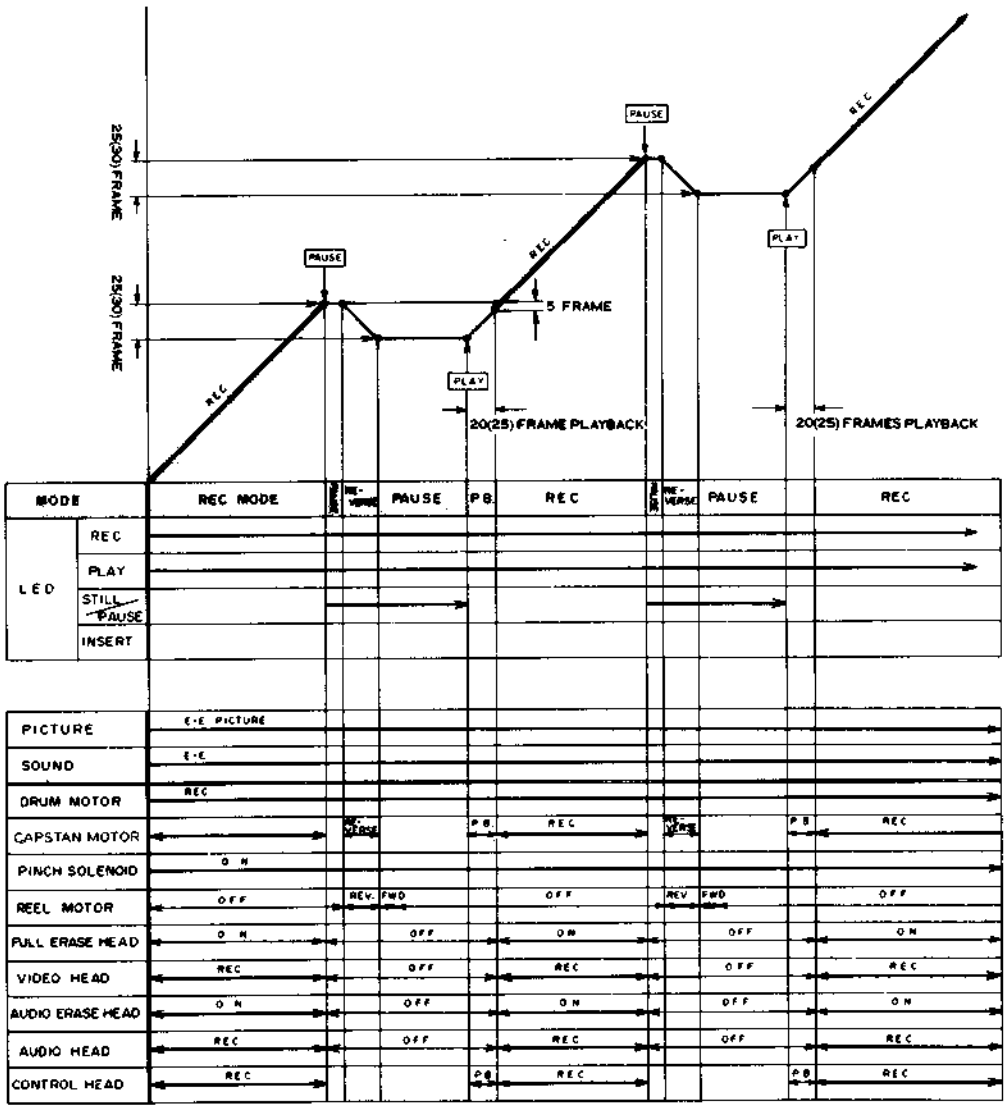

Fig. 3-17 The timing chart of the assembly editing

The servo system is synchronized to the control signal previously recorded on the tape during insert editing. In the normal playback mode, the capstan servo circuit is synchronized to an internal crystal oscillator and control is performed by comparison with the control signal phase. However, during insert editing, control is performed in synchronization with the input video signal. Thus, in effect, the system functions from external sync in the playback mode.

Proper adjustment of the TRACKING control is important during insert editing since the capstan servo circuit functions by playing back the control signal and adjusting the recording signal phase. This is particularly important when using a tape that was recorded on another VHS machine. If tracking error is present during insert editing, the lack of phase alignment between the base and newly recorded tracks could cause tracking problems.

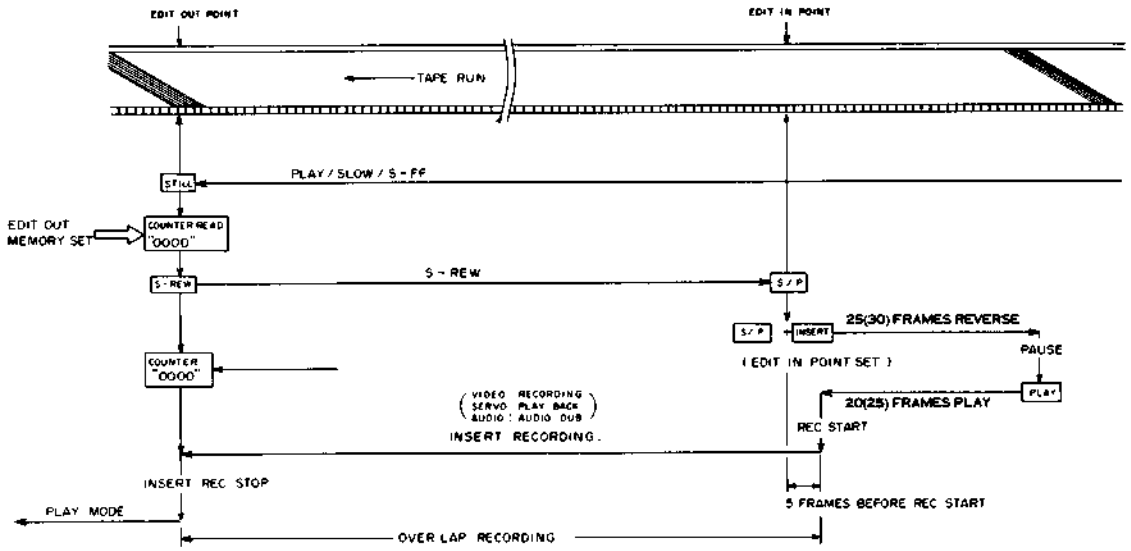

Fig. 3-18 Insert editing

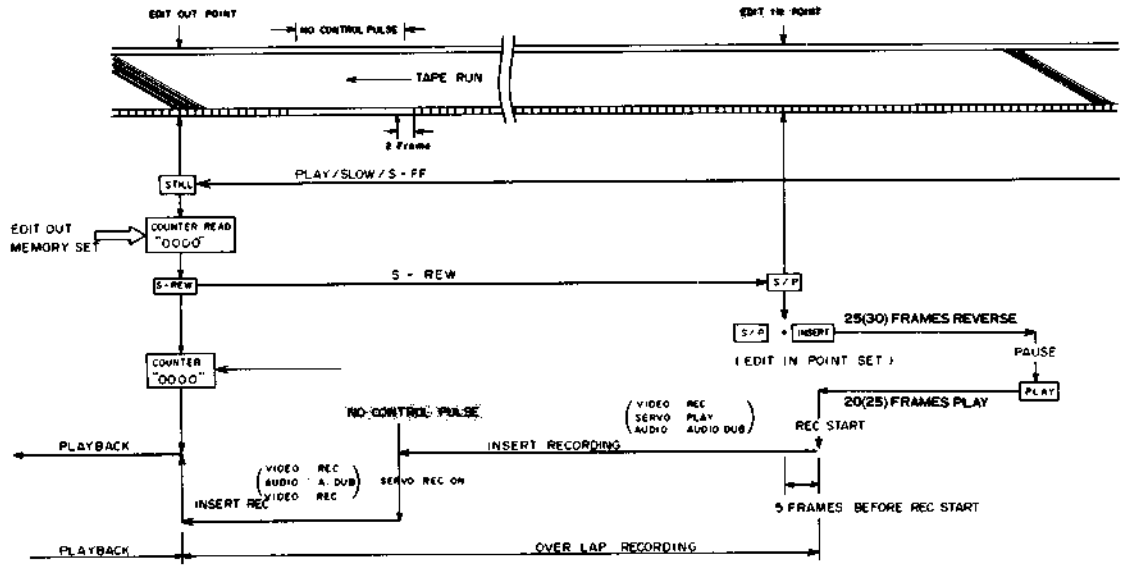

Fig. 3-19 Insert recording without control signal

3. Insert editing procedure
The timing chart of the insert editing is shown in Fig. 3-19.

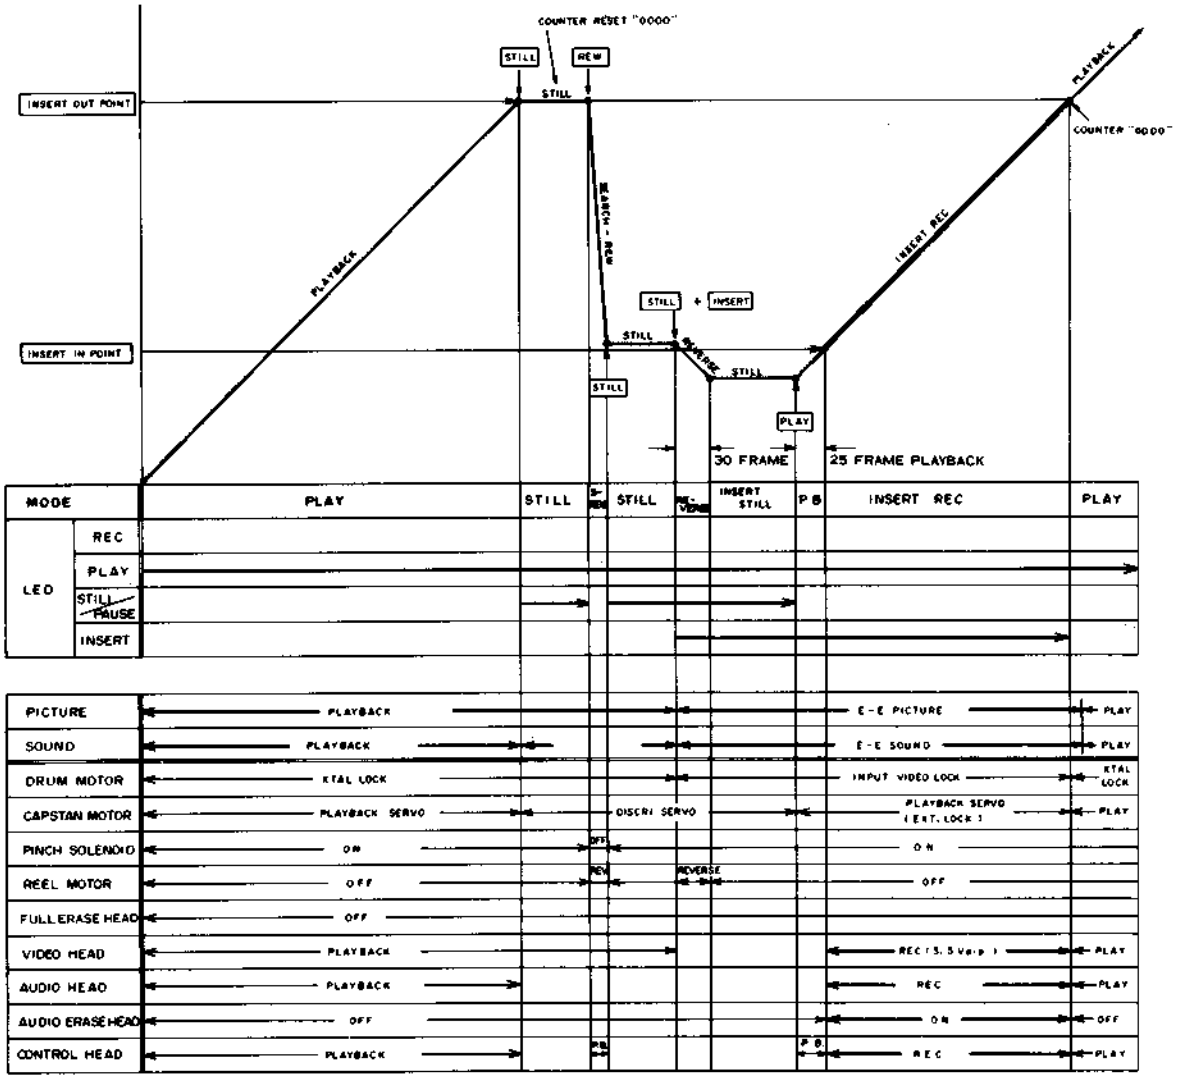

Fig. 3-20 Timing chart of insert editing

Before proceeding, check that A) the control signal is properly recorded on the tape and B) playback tracking is correctly adjusted for the tape to be edited.

1) Set insert editing end point
Play back the tape end, at the point insert editing is to end, press the counter RESET button. This resets the counter to 0000 and automatically sets the insert editing end point.

2) Set insert editing start point
After setting the end point, rewind the tape (or use search rewind) and determine the editing start point. At this point, press the STILL button. Then, to set the insert editing mode, simultaneously press the STILL and INSERT buttons.

3) Back space operation
When the insert mode is set, the capstan motor rotates in reverse for one second to rewind 30 frames of tape. This operation is controlled by the capstan FG pulse. At completion of reverse rotation, the capstan motor stops and the machine enters the pause mode.

4) Insert editing start
Press the PLAY button to begin insert editing. 25 frames are played back in order to synchronize the capstan servo, then insert editing begins at the CH-1 video head switching point.

5) End point operation
Insert editing continues until the tape counter reaches 0000 or the STOP button is pressed. At the insert editing end point, the capstan servo circuit switches over from the input video signal to the internal crystal oscillator. Although this results in some disturbance in the monitored (E-E) picture, it does not affect the insert editing end point.

3.2.6 CPU controlled slow and still modes

1. These modes are controlled by a newly developed 4 bit CPU system which possesses the following features.
   1) Even with tapes recorded on another (VHS) machine, optimum slow and still pictures are automatically adjusted.
   2) The system does not depend on the control signal recorded on the tape. Therefore, a monostable multivibrator system for control signal adjustment during recording and playback is not required.
   3) A slow tracking control is not required.
   4) Detection is performed for the FM signal and the FM noise position during slow and still.
   5) The previously required four adjustments for slow motion have been reduced to two.
   6) The servo board CPU (IC6) controls tape start and stop during slow and still modes, eliminating the need for complex additional circuits.
2. IC6 of the servo board and IC5 of the mechacon board, perform control for fine slow operation. The slow, still or frame advance signal from mechacon IC5 goes to servo IC6 to initiate the fine slow process. The following operations are then performed in sequence.
   1) Capstan motor stops.
   2) FM noise position is checked at the tape stopping point.
   3) The FM noise position address is derived from the drum FG count.
   4) FM noise position relative to the drum flipflop (CH-1 or CH-2) is computed.
   5) Capstan motor pulse output is produced.
   6) Return to step 2.
   7) Operation stops at the point the noise is eliminated from the picture.
   8) The capstan motor pulse output is obtained for a maximum of 8 times. If noise is not eliminated from the picture within these repetitions, operation stops at the 8th time.
3. FM noise position detection
   As indicated in Fig. 3-21, the CPU produces the slow pulse output and at the point the tape stops, the FM noise position is detected. When the tape stops completely, the CPU checks the FM noise position from the first drum flipflop rising pulse (CH-1 start).

   If the FM noise is positioned at the CH-1 and CH-2 switching point, or if it is undetected, the CPU determines that the motor advance pulse at the time is the best. In the case when the FM noise is at the CH-1 side, the CPU determines that the previous motor advance pulses was too short, then emits a pulse of slightly longer duration to shift the FM noise position rearward. Conversely, with the noise at the CH-2 side, the CPU interprets an excessively long pulse and sends a shorter one. In this manner, the FM noise position is detected and the capstan motor pulse width adjusted to remove noise from the slow/still picture.
4. FM noise calculation and slow pulse
   For accurate detection of the FM noise position, the CPU employs the 25 (30) Hz drum flipflop and 1600 (1920) Hz drum FG signals, as shown in Fig. 3-22.
   The drum turns 25 (30) times per second and the drum FG signal obtained from this rotation becomes 1600 (1920) Hz. By comparing this 1600 (1920) Hz with the drum flipflop signal, 60 drum FG cycles are obtained for each drum flipflop cycle.

   The CPU counts the rise and fall components of this 60 cycle drum FG signal, yielding 120 counts for each cycle of the drum flipflop. This 120 count is employed as the FM noise position address signal.

   Thus, an address signal below 60 indicates the FM noise position at CH-2, above 60 indicates CH-1, and at 60 becomes the optimum FM noise position. In this manner, the CPU detects the position of the FM noise from the address obtained from the drum FG signal and FM AGC output signal, then adjusts the width of the next capstan motor advance pulse.

   As an example, assume the FM noise is at CH-1. The CPU operation then becomes as follows.
   At the drum flipflop fall (CH-2 start point), the FM AGC DC component is applied to the CPU. The FM AGC input is 0 V DC with a normal FM waveform, but becomes a high pulse with the presence of level reduction (noise) in the FM waveform.

   The CPU continues counting the drum FG pulse until the FM AGC input goes high. In the Fig. 3-21 example, this occurs at count 30. Consequently, FG counter address 30 becomes entered into the memory as the noise start point. Thereafter, the CPU continues counting until the FM AGC input goes low (address 40 in the sample), and this becomes entered into the memory as the noise end point.

   From these data, the CPU computes the noise center as follows.

$$\frac{\text{Noise start (30)} + \text{Noise end (40)}}{2} = \text{Noise center (35)}$$

   After detecting the noise center address, the CPU determines the channel of the noise.

   Best noise point (60) – Noise center (35) = 25

   A positive value indicates FM noise position at the CH-2 side, while a negative value signifies the CH-1 side. A zero result denotes the optimum stopping point.

   The CPU then decides the capstan motor pulse. For the sake of illustration, assume that the FM noise is at the CH-1 side and the noise center at 35. The CPU calculation becomes:

   Best noise point (60) – Noise center (35) = 25

In this example, the noise position is at CH-1 and from the above data, the CPU determines that the previous motor pulse was too short by an amount corresponding to 25 address counts. The CPU then increases the length of the following pulse in proportion to 25 address counts, thereby setting the FM noise to the center 60 position.

5. Fine slow/still operation
   Refer to the timing chart. Pressing the SLOW/STILL button during playback sends the slow/still command to servo board CPU IC6, thereby setting the CPU to the slow/still mode.

   The CPU begins counting from the CH-1 start point and after a fixed time period (a), the capstan motor is stopped. The CPU then detects the FM waveform from the CH-2 start point.

   In this example, the FM noise is not detected. Therefore, the CPU issues the standard motor advance pulse output. After a fixed period from CH-1 start (d), a 60 msec motor pulse output is produced, which stops after time period (c).

   The FM waveform is then detected. If FM noise is detected, the CPU computes the noise center address (f) and the time difference (g) from the optimum position. The motor pulse start (h) and stop (I) points are determined, after which the motor pulse output is produced.

   In this manner, the noise position of the FM waveform is detected with every pulse input. If the optimum point is yielded twice in succession, the operation completes to provide a noise free still picture output.

3.3 VIDEO SYSTEM

3.3.1 General

Except for an occasional movie "classic", television broadcasts in recent years are nearly all in color. Furthermore, even with the now infrequent monochrome (black and white or b/w) broadcasts, it has become customary for broadcast stations to insert the color burst signal nevertheless. Consequently, circuits which formerly relied on the presence or absence of the burst signal for automatic switching between color and b/w modes are no longer of practical use. For this reason, this model does not include an automatic color killer circuit.

In practice, this trend is of minor consequence sicne the VHS format was originally developed on the premise that the input video signal would be in color.

The video mode select switch on the rear panel is provided with COLOR, B/W and CH SET positions. Normally the switch is set to the COLOR position, regardless of the input signal. When it is clear that the signal to be recorded or played back is b/w, the user can set the switch to B/W, thereby cutting off color noise which may appear in the picture. However, with this model, the recording frequency bandwidth of the luminance signal is not increased in the b/w mode.

Typically, the CH SET position is employed only when installing the set. At this position, the built-in video signal generator output through the RF converter is obtained at CH-36 for use in tuning the TV receiver.

The following circuit description is in reference to the block diagram.

3.3.2 Video control system

This model possesses capability for distinguishing among PAL, SECAM (standard), SECAM (modified, i.e., "ME-SECAM"), NTSC (standard) and NTSC (modified) systems for recording and playback. Single chip microprocessor IC1 of the VIDEO CONTROL board performs this detection and supplies the relevant data to other circuits.

In order to conserve power, the power supply is cutoff from those circuits which are not required in the particular mode.

Input and output data for IC1 and the VIDEO CONTROL board are indicated in the schematic diagram for reference during service. The decision flowchart for the microprocessor is depicted in Figs. 3-28 and 3-29.

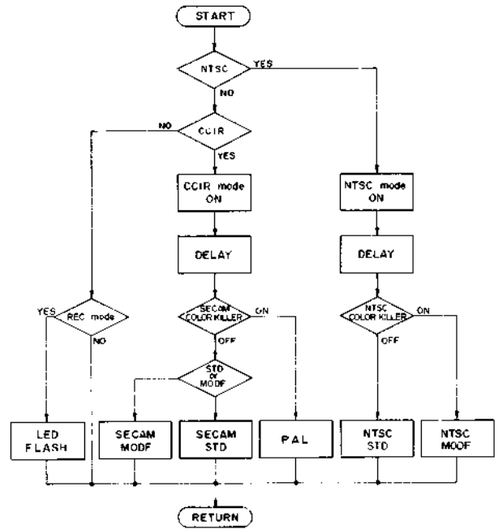

Fig. 3-28 Video signal det. (REC mode)

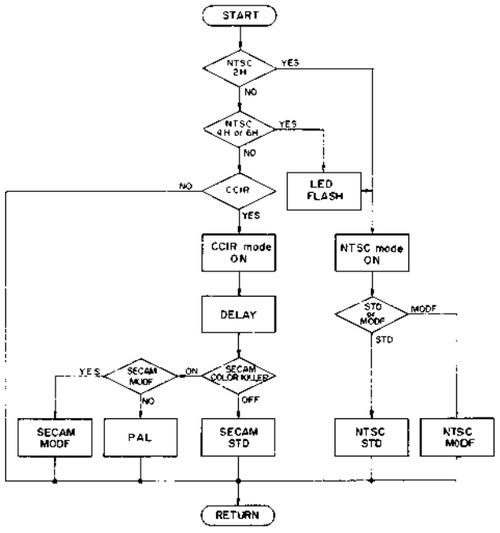

Fig. 3-29 Video signal det. (PB mode)

3-28

3.3.3 Luminance signal system

Refer to the luminance signal block diagram of Fig. 3-35.

1. Recording system

Video inputs consist of tuner, auxiliary (AUX) and camera. At the VIDEO CONTROL board, the TV broadcast signal selected by the tuner is demodulated and supplied as a video signal to connector 221. If an auxiliary video signal source is connected to the rear panel, this becomes supplied to connector 213. Similarly, a video signal via the CAMERA connector becomes applied to connector 111.

The user employs the REC SELECT switch to choose the desired of the three inputs. This is coupled with electronic switch IC3, which is off during playback and cutoff from succeeding circuits.

An emitter-follower converts the impedance of the signal through IC3, which then goes via connector 182, the NTSC COLOR board and the COLOR board to connector 51 of the Y & PRE/REC board.
This video signal is supplied to IC106 pin 26.

The keyed AGC (automatic gain control) circuit functions to control the sync level of the video signal for a fixed value, after which the output is obtained through SW-2 at IC106 pin 24.

Emitter-follower Q110 converts the impedance and supplies the signal to Q108.
L109 and C125 function only during playback mode.

Emitter-follower Q108 converts the impedance and lowpass filter removes the unnecessary highband color component. Between Q108 and LPF, a series resonance trap formed by Lxxx and Cxxx functions as a subfilter trap for LPF and attenuates the center energy band of the color signal. The trap possesses a center at the color subcarrier frequency.

At equalizer, the luminance signal is delayed approximately 600 nanoseconds (600 x 10^{-9} sec) to match the timing with the color signal on the recorded tape pattern. The combined response of LPF and EQ serves to improve the pulse response of the luminance signal.

Emitter-follower Q104 again converts the impedance of the signal from EQ and supplies it to IC106 pin 13, where it is amplified to a level sufficient for driving the pre-emphasis and frequency modulator circuits. The signal is obtained via SW-3 from IC106 pin 14.

The pin 14 output is branched into two lines. One of these goes through C183 to IC106 pin 28 and through a lowpass filter to pin 1 for the keyed AGC detector.

The second line is for luminance signal processing and enters IC106 pin 18 through low pass filter formed by C186 and L131 for supply to the clamp, nonlinear pre-emphasis and main pre-emphasis circuits.

The nonlinear pre-emphasis circuit functions to automatically vary the pre-emphasis amount according to the input video signal level, increasing the amount at low signal levels, where noise is most easily apparent. In combination with the main pre-emphasis circuit, signal to noise ratio (S/N) is improved in the mid and high frequency regions of the signal. For this reason, a keyed AGC circuit is required, rather than a peak AGC circuit.

By applying pre-emphasis, strong waveform spikes are produced in the rise component from black to white level. Since this could cause black/white reversal effects, in addition to white and dark clipping, waveform shaping is performed to permit demodulation during playback.

Sync tip of the luminance signal from IC107 pin 18 is clamped at a fixed DC potential before going to the nonlinear pre-emphasis circuit. This is intended to reduce the amount of pre-emphasis at high level and high frequency.

Pre-emphasis is applied at the main pre-emphasis circuit without regard to level. White and dark clip circuits cut the spike components above and below fixed levels, and the resulting signal goes to the frequency modulator.

In another route, the signal from the white and dark clip circuits goes from IC107 pin 12 to emitter-follower Q138 for impedance conversion. De-emphasis is performed by an RLC circuit, demodulating the spike components. The signal then goes to the main pre-emphasis circuit where only the peaks of the spikes are compressed. This allows demodulation of the spike components during playback and improves S/N and pulse characteristics.

Pin 12 of IC107 is a fixed current power supply terminal. According to the DC potential of the video signal from the white and dark clipping circuits, the oscillation frequency of the frequency modulator (FM MOD) varies. The variation is linear with respect to the video signal DC potential.

As can be noted, the highband overshoot component lost by white clipping becomes effectively restored for driving the frequency modulator. Consequently, demodulation of the highband component is improved, together with S/N at high frequencies.

The 25 Hz drum flipflop signal is supplied to the common of R291 and R293 (CARRIER) in order to reduce visibility of the noise.

This model employs video heads track width more than 49 μm. During playback, a small crosstalk component is picked up from the adjacent track. Also, even a slight deviation from the horizontal correlation of the VHS recorded tape pattern sharply increases the crosstalk amount.

Due to the azimuth angle of the video head, the FM crosstalk component is located at the lower FM sideband, where the frequency is low. Through the demodulator, the crosstalk contributes to highband noise in the video signal.

By adding the 25 Hz drum flipflop signal to the frequency modulator, the FM carrier frequency of the CH-1 and CH-2 track components from the frequency modulators shifted by 1/2 Fh.

The sync tip FM carrier frequency of CH-1 track becomes 3.8 MHz and CH-2 becomes 3.8 MHz plus 1/2 Fh. Consequently, the sideband components of the CH-1 and CH-2 tracks become an interleaved frequency spectrum. When this is played back, the crosstalk component becomes offset by 1/2 line with respect to the main signal, thereby reducing visibility.

This FM carrier interleaving circuit improves edge noise which occurs at rapid transitions from black to white level.

R293 (R291) adjusts the sync tip to 3.8 (3.4) MHz and R203 (R201) adjusts for 100% white peak level at 4.8 (4.4) MHz. Since the high frequency component of the input luminance signal and the FM frequency are in the same region, it is important to avoid input leakage and obtain high linearity and symmetry in the output.

The FM luminance signal goes via SW-4 and IC107 pin 28 to the next stage highpass filter, which attenuates the lower sideband where the down converted color signal is to be inserted. Emitter-follower Q128 converts the impedance, after which the signal is mixed with the down converted color signal and supplied to recording amplifier REC AMP-1 at IC107. As indicated in the block diagram, this amplifier possesses the proper frequency characteristics for recording the FM signal on the tape. The recording current is selected for the optimum playback output with respect to the FM signal frequency.

From REC AMP-1, the signal goes to REC AMP-2, which is a broad-band amplifier. In order to match the low impedance of the rotary transformers and video heads, the SEPP (single ended push-pull) circuit of Q140 and Q141 supplies nearly a fixed current to the video heads.

The recording FM signal from REC AMP-2 is branched and go from conns. 111 and 116 to the rotary transformer. IC109 is an electronic switch which sets the rotary transformer and consequently the video heads for the recording or playback mode. In the recording mode, SW11 and SW14 are off, while SW12 and SW13 are on. Both CH-1 and CH-2 are grounded through 10 Ω resistors at conns. 112 and 115, setting the rotary transformers for the recording mode. Together with R251 (R249) these resistors adjust for the optimum recording current to the video heads.

Electronic switch Q130 is on in the E-E and REC modes, at which time R254 (470 Ω) attenuates the FM signal. However, during insert editing, the INSERT CTL command (low potential) at D106 cathode switches Q130 off. Consequently, the FM signal level supplied to the video heads becomes about 2.5 dB higher in the insert editing mode than during the normal recording mode.

The E-E output during recording is obtained from the keyed AGC circuit. This signal is mixed with color and goes via the E-E amplifier, switch SW5 and an emitter follower circuit to IC106 pin 5, then to the E-E video output.

2. Playback system

Electronic switches SW11 and SW14 are on during playback, while SW12 and SW13 are off. These states set the rotary transformers for the playback mode and the video heads pick-up the signal from the tape. The playback signal channels from the video heads go to the CH-1 and CH-2 pre-amplifiers of IC107, which are designed for both impedance matching between the video heads and rotary transformers, and optimum S/N.

Head resonance controls C333 & C334 and head quality factor controls R361 & R336 compensate for response differences between video heads and reduce S/N impairment due to such difference.

At the switching amplifier, the CH-1 and CH-2 segments are joined into a continuous signal in accordance with the drum flipflop signal, which is synchronized to video head rotation. The outputs of the two head channels are arranged with a front and back overlap of about 7 to 8H, which eliminates signal loss at the junctures and yields a completely continuous waveform. This playback FM signal is obtained via SW5 from IC107 pin 28.

Since the down converted color signal is included at this point, in one route, the signal goes to the color signal playback circuit. In another route, for demodulating the luminance signal, a highpass filter removes the low-band color signal. This filter possesses the same response as that for recording.

The signal also goes from IC107 pin 27 to the FM AGC circuit.

The FM AGC circuit is used for precisely driving the dropout compensator (DOC). Dropout refers to intermittent loss of signal due to imperfections in the tape. When this occurs, the DOC insert the signal from the previous horizontal scanning line, thereby minimizing visible effects in the picture.

From this point, the corrected signal goes from IC107 pin 22 to a highpass filter, which removes the low-band color signal. This filter possesses the same response as that for recording.

The FM equalizer amplifier compensates to obtain a flat output.

An emitter-follower converts the impedance of the signal, which then goes to the equalizer.
The equalizer possesses a maximum delay by 50 msec at the carrier frequency and reduces edge noise at the transition from black to white level.

An emitter-follower again converts the impedance of the signal, which then is branched in two directions. One goes to the double limiter circuit of IC106 pin 16. The double limiter possesses an approximately 80 dB limited gain for precisely driving the demodulator and also functions to prevent black/white reversal.

The limited FM signal waveform becomes a precise squarewave and enters the demodulator. The demodulator is a phase detecting type using a delay line. Through SW2, the resulting AM luminance signal goes from IC106 pin 24 to an emitter-follower, then to LPF, where it is integrated to become the demodulated video signal. In addition to functioning as an integrator, LPF reduces FM carrier leak and attenuates the band where the playback color signal is to be inserted.

L109 & C125 between Q108 and Q110 from a lowpass filter and LC functions as a color subcarrier frequency trap and selectively attenuate the central energy region of the color signal. EQ delays the luminance signal by about 600 nsec to match the timing of the color signal at the playback output. The combined characteristics of LPF and EQ improve the pulse response of the luminance signal.

The signal through EQ goes via an emitter-follower a broad band to an amplifier.

During recording, the drum flipflop signal is supplied to the frequency modulator, shifting the CH-2 track 1/2 Fh with respect to the CH-1 track. By this, during playback, the crosstalk component from the adjacent track becomes 1/2 line offset relative to the main signal.

In the playback mode, by employing the above relationship, together with the correlation between video signal lines *n* and *(n − 1)*, and the random nature of the noise component, the noise component becomes reduced and S/N improved.

As a consequence of including FM interleaving and noise canceller functions, the playback luminance signal is passed through a comb filter which possesses the luminance signal spectrum.

The signal through the equalizer goes to the equalizer amplifier, where the midband component is increased to improve picture sharpness and softness. This signal is sent through the subcarrier trap to pin 8 of IC101. R105 determines the luminance signal level during playback.

With a CCIR (PAL or SECAM) signal, noise reduction at the VIDEO SUB board employs horizontal correlation of the Y signal for suppressing noise.

The demodulated luminance signal is applied to VIDEO SUB board connector 16 and the 1H delayed FM signal to connector 11. The delayed FM signal goes to the limiter and demodulator at IC1 pin 2. A lowpass filter cuts the high frequency component (i.e., color signal) to yield the luminance signal. This is delayed by the equalizer and sent via R11, which adjusts the level, and an emitter-follower to IC1 pin 10.

At the same time, the luminance signal from which noise has been removed appears at pin 11. These are subtracted at the differential amplifier to yield the noise component, which is sent to the clip and highpass amplifier circuits.

After cutting the DC component of the noise, the result is inverted and mixed with the playback luminance signal. The luminance signal with attenuated noise appears at pin 16.

The noise canceller circuit attenuates the highband component of this signal, while the equalizer amplifier and de-emphasis circuits raise the midband component. The signal then goes via an emitter-follower and electronic switch to connector 21 of the Y & PRE/REC board.

R101 determines the signal level applied to IC101 pin 7. In this IC, an emitter-follower converts the impedance of the signal corresponding to the mode and supplies it to IC106 pin 12.

This circuit operates in the opposite manner as the non-linear pre-emphasis circuit for recording and increases the amount of de-emphasis as the signal level decreases. Another function of the main and non-linear de-emphasis circuits is to demodulate the clipped overshoot and undershoot components produced by the pre-emphasis circuits.

Excess de-emphasis can impair resolution. Therefore, the amount of de-emphasis is slightly less than the amount of pre-emphasis, after which the noise canceller reduces high frequency noise.

At the Y/C mixer circuit, the luminance signal from the noise limiter via SW3 and the squelch circuit is mixed with the playback color signal. This becomes the output of IC106 through SW5 and emitter-follower circuits.

The IC106 output goes from conn. 92 of the Y / PRE/ REC board to conn. 42 of the VIDEO SUB board, where it is supplied to the video pulse equalizer circuit formed by IC101, Q101 and EQ.

The video pulse equalizers circuit serves to improve pulse response and reduce edge noise by introducing preshoot into regions of rapid transition from black to white level, and from white to black level.

During recording, since Q101 switches ON, the delay time of EQ is zero.

The output goes via conn. 52 to emitter-follower Q11 of the VIDEO CONTROL board.

This transistor normally functions as an emitter follower, but when the video mode select switch is set CH SET, it becomes cutoff by high applied to D4.

The clamp circuit formed by D13 and Q10 fixes the sync tip of the video signal, which is then branched into two lines. One of these goes through Q13 emitter-follower to VIDEO CONTROL board conn. 111, then to the camera connector output. The other output of the clamp circuit is supplied to Q9 emitter-follower.

VIDEO CONTROL board conn. 111 is the camera signal in/out terminal. It functions for video input during recording and video output during playback. In the playback mode, approximately 4.6 V DC is superimposed on the video output signal. These functions are obtained only when the REC SELECT switch is set to CAMERA.

Electronic switches Q12 and Q14 are on in the REC and E-E modes. Q12 functions to cut off the video signal, while Q14 terminate the camera signal at R56 (75 Ω).

The video signal from Q9 goes through R39 to color board conn. 215, then to the rear panel VIDEO OUT connector. The signal also goes through EQ1, and mixer Q7 and Q8 to conn. 241, then to the RF converter. EQ1 delays the lowband luminance signal by approximately 170 nsec.

IC4 video signal generator functions only when the video mode select switch is set to CH SET. This output is supplied to the RF converter.

3. Special circuit descriptions

1) Keyed AGC circuit

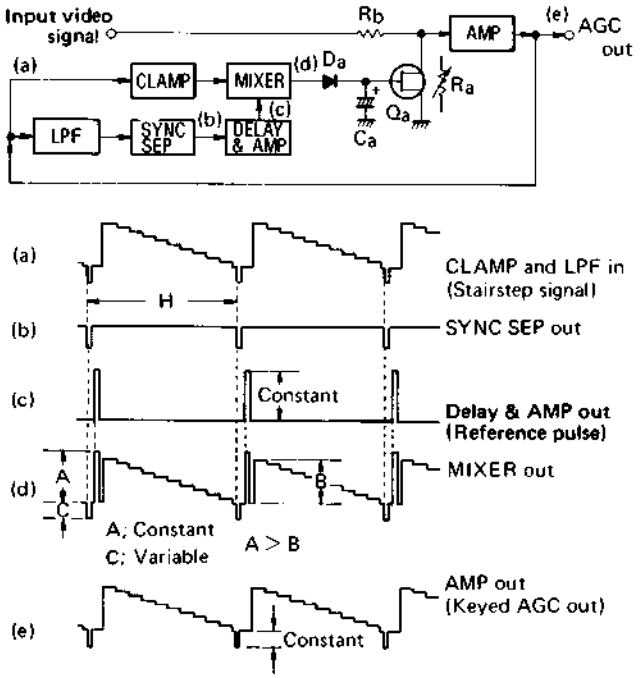

Fig. 3-30 Keyed AGC principle

The AGC out signal appears at the clamp and LPF as waveform (a). Sync tip is clamped at a fixed DC potential and the signal is supplied to the mixer. Waveform (b) is obtained following sync separation through a lowpass filter. This is delayed to match the phase of the back porch of waveform (a) horizontal sync component, amplified to a fixed level and mixed to become waveform (c).

At the mixer, the H sync back porch is mixed at a fixed level which is slightly higher than the 100% video level, as indicated by waveform (d). Level of this added reference pulse is fixed and the signal is rectified by Da and Ca. The rectified voltage varies the impedance (Ra) between Qa drain and source. Level of the input video signal supplied to the amplifier becomes controlled by the ratio of Ra to Rb.

For example, when the input signal level is high, the sum of the sync and reference levels increases and the rectified output becomes larger. When applied to Qa gate, this larger voltage decreases the impedance Ra between Qa source and drain. As a result, the input level to the amplifier becomes attenuated by the ratio of Ra to Rb.

In the above manner, because of the fixed added pulse level, the rectified output becomes determined by the sync level. By this process, the keyed AGC circuit functions to maintain a fixed sync level.

An advantage of the keyed AGC circuit is that its output level does not vary with change in the average picture level (APL) of the input video signal. This permits use of the above mentioned non-linear pre-emphasis system.

2) Dropout compensator circuit

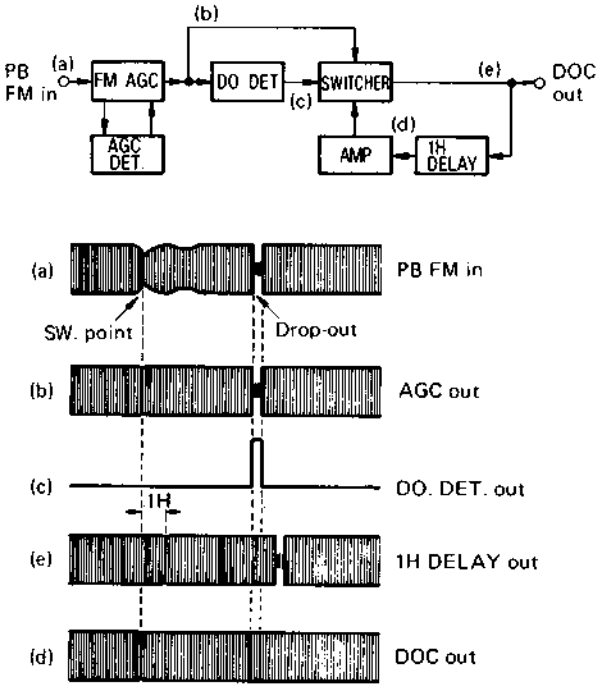

Fig. 3-31 Dropout compensator

Detects in the tape, such as magnetic particle losses, can cause loss or reduction of the FM signal, which may impair picture quality. When this occurs, the dropout compensator functions to insert the FM signal from the previous horizontal line, thereby preventing visible effects in the picture.

The FM AGC circuit first corrects for level fluctuations in the playback FM signal, which arise from variations in head to tape contact at the intake and output of the rotating drum. This results in a fixed level as indicated by waveform (b) in Fig. 3-31.

Part of this output goes directly to the switching circuit, while another part is applied to the dropout detector. In the dropout detector circuit, a highpass filter cuts the low sideband of the FM signal and an integrator detects the dropout component. A precise squarewave is formed and supplied as waveform (c) to the switching circuit.

A 1H delay circuit and amplifier return part of this signal to the switching circuit as waveform (d). When (c) is low, output (b) is produced from the switcher. In event of dropout, (c) becomes high and output (d) is obtained. In this manner, the signal from the previous horizontal line becomes inserted in place of the dropout component. The loop circuit design of the DOC increases its effectiveness.

3) Double limiter circuit

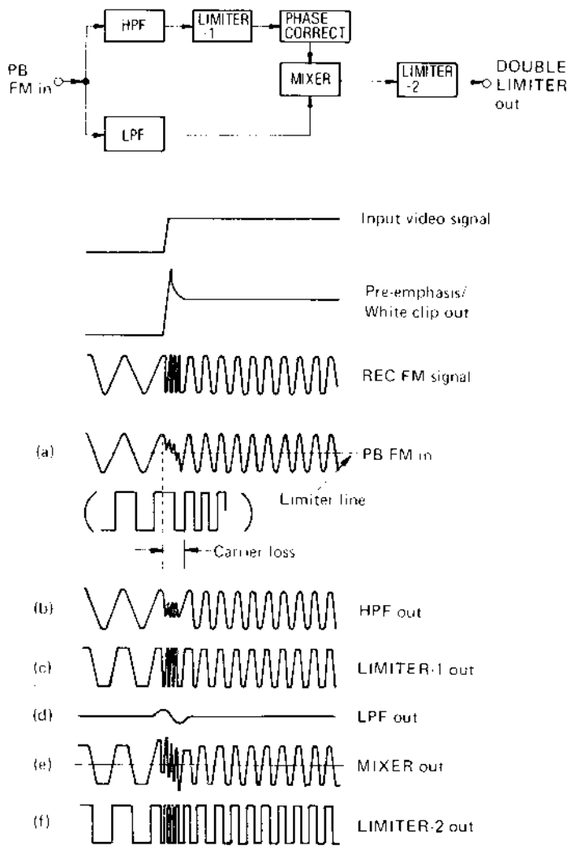

Fig. 3-32 Double limiter principle

Overshoot can result when pre-emphasis is applied to a signal which varies from black to white level. The playback FM signal is indicated by waveform (a) in Fig. 3-32.

If limiting is applied at the limiter line at the center of the waveform excursion, it cannot correct the carrier loss component and black/white reversal and impaired S/N can occur. For this reason, the signal is applied to highpass and lowpass filters which separate the carrier and lower sideband components, as indicated by (b) and (d).

The signal through the highpass filter goes to Limiter-1 which applies approximately 10 dB limiter gain, then to the mixer. At the mixer, the signals from the HPF and LPF are mixed and sent to Limiter-2. This is shown by waveform (e).

Phases of the signals are aligned by the phase correct circuit. As can be noted from waveform (e) limiting can be applied to the lower sideband component without losing signal information.

With the double limiter, the noise component is not amplified, while the carrier and lower sideband ratio is corrected. This serves to eliminate carrier loss and prevent black/white reversal. As a result, adequate pre-emphasis can be applied for improved S/N at high frequency.

4) Demodulator circuit

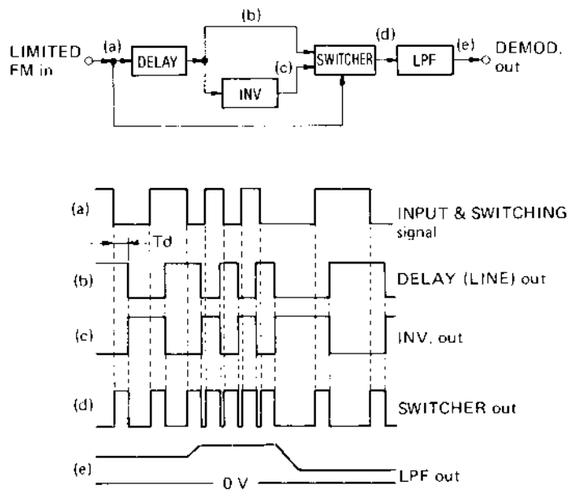

Fig. 3-33 Demodulator principle

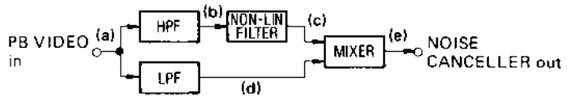
Part of the signal from the limiter goes directly to the switching circuit as the switching pulse. In the other route the signal goes through a delay circuit, then to the switcher as waveform (b) in Fig. 3-33.

The delayed output through the inverter enters the switcher as waveform (c). Since the delay amount (Td) is 1/4th the FM carrier period of 4.3 MHz, it becomes approximately 0.058 μsec.

A low switching pulse (a) produces the switching circuit output shown by (b), while a high pulse results in (c). Consequently, the switching circuit output becomes as shown by waveform (d). This is integrated through a lowpass filter to yield the AM luminance signal indicated by (e).

In the block diagram, the delay amount is determined by C174 between pins 21 and 22 of IC106.

5) Noise limiter circuit



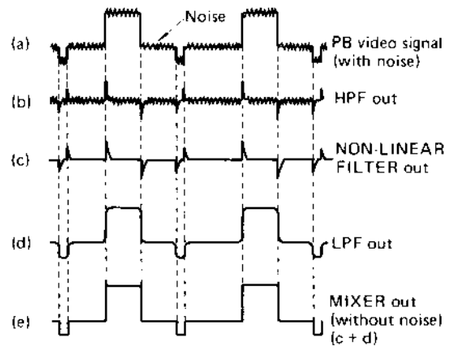


Fig. 3-34 Noise canceller principle

The signal played back from the tape contains FM noise at high frequencies, as indicated by (a) in Fig. 3-34. This is applied in two lines to highpass and lowpass filters to become waveforms (b) and (d).

Noise in the plateau section of the video signal, which may easily affect the picture, becomes concentrated in the low level portion of the signal through the highpass filter. The non-linear filter functions to remove this noise to produce waveform (c). Waveforms (c) and (d) are then mixed to yield noise free waveform (e).

By varying the mixer input level, contour clarity can be varied to produce the visual effect of improving resolution.

3.3.4 NTSC color signal

1. Recording system

The color TV signal selected at the input switching IC and IC3 is supplied to E. SW (Q403). Q403 is set to ON during recording, so that the input video signal is sent to the band-pass filter BPF402, where only the color signal component with its energy centered on the color subcarrier (3.579545 MHz) is extracted, while the unnecessary luminance signal component is removed. In addition, Q403 functions to do the switching of REC/PB of IC401 and, when IC401 pin 22 becomes more than 6 V or Q403 is set to ON, IC401 becomes the REC mode. The color signal component passing through BPF402 goes from IC401 pin 4 to the ACC AMP. The ACC (Automatic Color Control) functions to control the output level to maintain the output burst level constant with the output branching off into two directions. One is supplied to the ACC DET, APC DET and KILLER DET. The ACC DET operates to extract the burst signal by means of the burst gate pulse from the burst gate pulse generation circuit, maintaining the ACC AMP at this level. The other signal is sent to the circuit block which comprises the MAIN CONVERTER, BURST EMPHASIS and KILLER AMP. In addition to the ACC AMP output, the subconverter output, KILLER DET output and burst gate pulse are also supplied to this circuit block, where the color signal of 3.58 MHz from the ACC AMP is frequency converted into 40 fH by means of the converter output of 4.21 MHz (3.58 MHz + 40 fH) and then converted into the signal with only the burst increased by 6 dB.

When the input signal is a black/white signal, the circuit block output is set to OFF by means of the signal from the KILLER DET. The low band converted color signal which is output from IC401 pin 1 is sent to LPF401, where the extra component other than the 40 fH component is removed. After the color signal recording current is adjusted at R452 (REC COL. LEV.), it is mixed with the FM of the luminance signal and then the FM signal of the high frequency and high level is recorded on the tape as AC bias. This is mixed with the luminance signal through E.F. (Q405) and then recorded on the tape.

The SUB CONV. functions to convert the frequency by means of 40 fH (629 kHz) from the AFC loop and Fs (3.58 MHz) from the APC loop. Because the SUB CONV. output contains the signal component of sum and difference, the sum component of 4.21 MHz (Fs + 40 fH) is extracted at the band-pass filter BPF401 and sent to the MAIN CONV.

2. AFC (Automatic Frequency Control)

The AFC Loop performs the following functions:

1) Generation of the 40 fH signal (40 x 15.734 kHz ≒ 629 kHz),
2) To shift the 40 fH signal phase by 90° every 1H, and
3) Phase correction of the horizontal sync signal.

The input video signal is sync separated at the sync signal separator circuit within IC106 and the horizontal sync signal is sent from pin 3 of IC106 to pin 6 of IC401. The horizontal sync signal containing only H with the 1/2H sync signal of V sync signal portion cut off at the 1/2H PULSE KILLER is sent to the burst gate pulse generator circuit as well as the phase shift circuit and AFC detector circuit.

The latter circuit is a phase comparison circuit of the AFC Loop and the reference signal is a horizontal sync signal, while the comparison signal is an fH signal of 1/160 count-down of the 160 fH VCO (Voltage Controlled Oscillator) output. The error output from the AFC detector circuit is supplied to the 160 fH VCO and the VCO oscillates at 160 fH (160 x 15.734 kHz). The 160 fH signal is sent to both the 1/4 and 1/160 count-down circuits. The signal counted down to 1/160 becomes fH, which is phase compared with the horizontal sync signal of the input video signal at the AFC detector circuit. Since the reference horizontal sync signal is constant, the error output also becomes constant and the 160 fH VC is so arranged at R230 (AFC) to oscillate exactly at 160 fH. The 160 fH signal sent to the 1/4 count-down circuit is converted into 40 fH and then fed to the phase shift circuit, to which the drum flip-flop signal and H sync signal are also supplied. The output from the phase shift circuit is 40 fH. The phase of the signal to be recorded at the CH-1 head every 1H gains by 90°, while that of the CH-2 head signal inversely loses by 90°. This 40 fH signal is sent to the sub-converter circuit as the AFC output.

3. APC (Automatic Phase Control)

The ACC AMP output is also sent to the APC detector circuit. This detector circuit comprises a phase comparison circuit of the APC Loop, which functions to perform the phase comparison of the reference signal, ACC output burst signal, with the 3.58 MHz VCO output which produces the comparison signal by means of the burst gate pulse. The error voltage is added to the 3.58 MHz VCO, which generates a signal of 3.58 MHz condordant with the input color signal phase and feed it to the sub-converter.

4. Playback system

The PB signal played back from the video head is amplified and switched at IC107 of the Y & PRE/REC board. IC107 operates in the same manner as the luminance signal playback system.

The FM signal amplified at IC107 is supplied from pin 28 to the luminance signal playback system, while it is also sent from CONN. 141 to CONN. 11 of the P.B. CHROMA AMP board and then supplied via the bias trap L2, C2 to the low-pass filter LPF2. This bias trap functions to prevent the erase head signal during audio dubbing from being mixed with the color signal playback system.

LPF2 attenuates the unnecessary luminance signal component and extracts only the low band color signal, which is supplied to the amplifier made up of IC2 after the timing with the playback system luminance signal is matched at the equalizer IC2.

After this, the playback color signal is sent from IC401 pin 24 to the main converter. Since the 3.58 MHz + 40 fH signal is sent from the sub-converter to the main converter as is the same with recording, the output is restored to the original 3.58 MHz color signal.

The actual played back signal contains time axis variations (frequency and phase variations) due to changes in the tape speed, rotation irregularities of the video head and expansion and contraction of the tape. This means that when the played back low band conversion color burst signal is Fsc', it is played back as Fsc' = 40 fH' ± Δf. Here fH' represents fH ± ΔH, i.e. frequency variations due to changes in the tape speed, etc. It is the frequency DISCRI circuit consisting of a block, including the GATE circuit, COUNT-DOWN circuit and DECODER DET. that functions to correct such a big variation as 40 fH'. (Description of the frequency DISCRI circuit will be made later.)

A small variation like ± Δf caused by rotation irregularities of the video head and expansion and contraction of the tape is corrected at the APC Loop. In the normal playback condition, frequency and phase variation are corrected at the APC Loop alone. The frequency DISCRI circuit operates only when the frequency variation exceeds the APC Lock range, bringing it back quickly within the range.

These correction signals control the 160 fH VCO to let it oscillate at 160 fH' ± 4Δf. This output is counted down to 1/4 and converted into 40 fH' ± Δf and then sent to the phase shift circuit. Here, as is the same with recording, the phase is advanced by 90° every 1H for the CH-1 playback, while it is delayed by 90° for the CH-2 playback. The resultant output is then sent to the sub-converter. Since a constant signal of 3.58 MHz is sent to the sub-converter from the 3.58 MHz VCO, the sub-converter output becomes (3.58 MHz + 40 fH' ± Δf) and (3.58 MHz − 40 fH' ∓ Δf). The band-pass filter BPF extracts (3.58 MHz + 40 fH ± Δf) component from the sub-converter output and sends it to the main converter. Therefore, the main converter output is the sum and difference component of the playback color signal 40 fH' ± Δf and BPF401 output (3.58 MHz + 40 fH' ± Δf), which produces a color signal without the difference component 3.58 MHz, i.e. variation. The resultant playback color signal is then sent to the ACC AMP. The ACC AMP output becomes a constant burst level, thereby cancelling the color crosstalk at DL401.

The output from DL401 is branched off into two directions: one is supplied as a comparison signal to the ACC detector circuit, APC detector circuit and KILLER detector circuit, while the other is restored to the original burst level by lowering the 6 dB up converted burst signal level by 6 dB at the BURST DE-EMPHASIS circuit. This block also performs the KILLER operation by means of the KILLER detector circuit output.

The color signal output from IC401 pin 20 is sent to IC106 pin 7 after the leakage of the unnecessary sum component (3.58 MHz + 80 fH) out of the main converter output is attenuated at the TRAP circuit of L402. C402 and the playback color level is adjusted at R700. This signal is mixed with the luminance signal at the Y/C MIX circuit, thereby becoming a playback video signal.

After this point, the signal flow is the same as the luminance signal playback system.

5. Frequency DISCRI circuit

Fig. 3-36 shows a block diagram and properties of the frequency DISCRI (discriminator) circuit. The frequency DISCRI circuit counts the output from the 160 fH VCO and sents the signal by which to control the 160 fH VCO when the frequency deviates more than ±1/2 fH. Actually, it counts the 160 fH VCO output for the 4H period and 160 fH is equivalent to 640 pulse with 1/2 fH corresponding to 2 pulse. The 160 fH VCO output is sent to the COUNTER circuit only for the 4H period at Gate 1. A gate pulse of 4H is supplied from the 1/8 dividing circuit go Gate 1. The pulse number during this 4H period becomes 630 ± n. The COUNTER circuit counts the pulse during this period and sends two kinds of signals. One sends an output, whose polarity changes depending upon if the pulse number is more or less than 640, to the DECODER circuit, while the other sends to Gate 2, a gate pulse of High at the time of 640 ± 2 (638 –642) and that of Low at other times.
When gate pulse from the COUNTER circuit is Low, Gate 2 supplies the pulse from the 1/8 dividing circuit to the DECODER circuit, which means that the DECODER circuit functions only for the 1H period every 8H.

Therefore, as is shown in Fig. 3-36, the DECODER output supplies three different outputs: a zero output when the pulse number is 640 ± 2 (i.e. 160 ± 1/2 fH), an output by which to increase the oscillation frequency when it is less than 638 (i.e. 159.5 fH) and an output by which to decrease the oscillation frequency when it is more than 642 (i.e. 160.5 fH). The portion of a zero output is corrected at the ALC Loop.

6. APC circuit

To the phase comparison circuit, a crystal oscillator output of 3.58 MHz as the reference signal and a playback color signal containing phase variations as the comparison signal are being supplied. The error voltage is sent to the 160 fH VCO and collaborates with the frequency DISCRI output to control the 160 fH VCO.

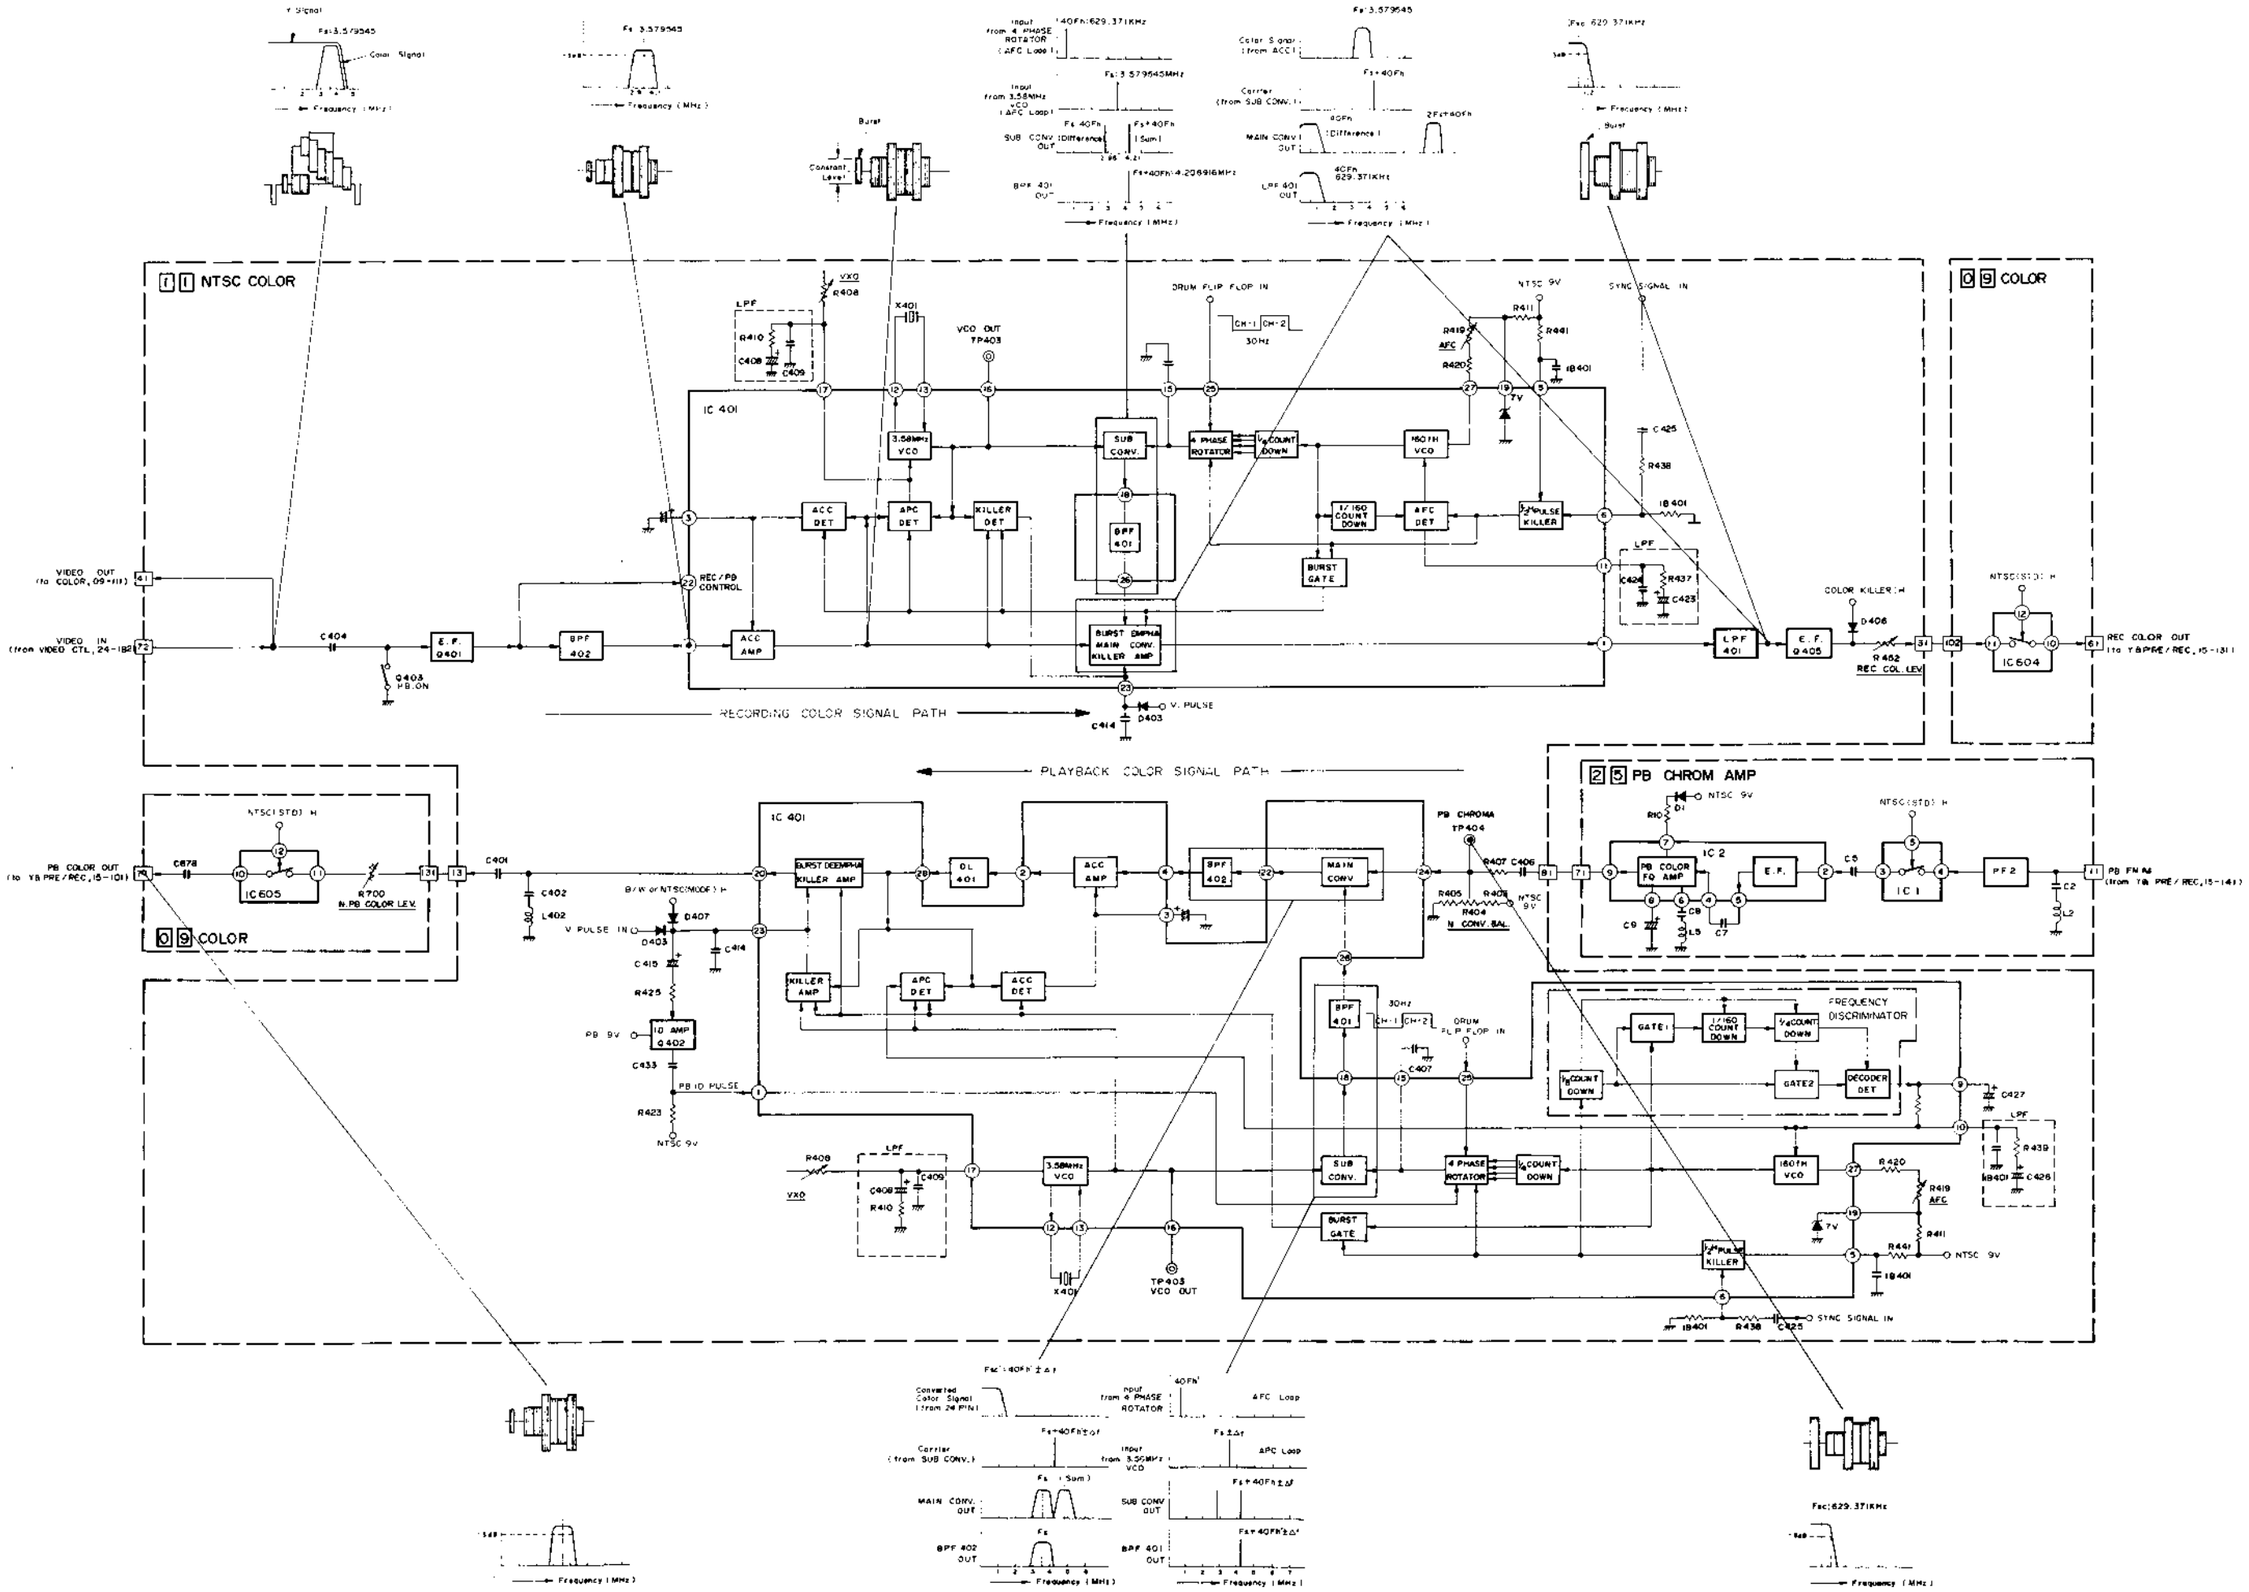

Fig. 3-36 NTSC color signal block diagram

3-37

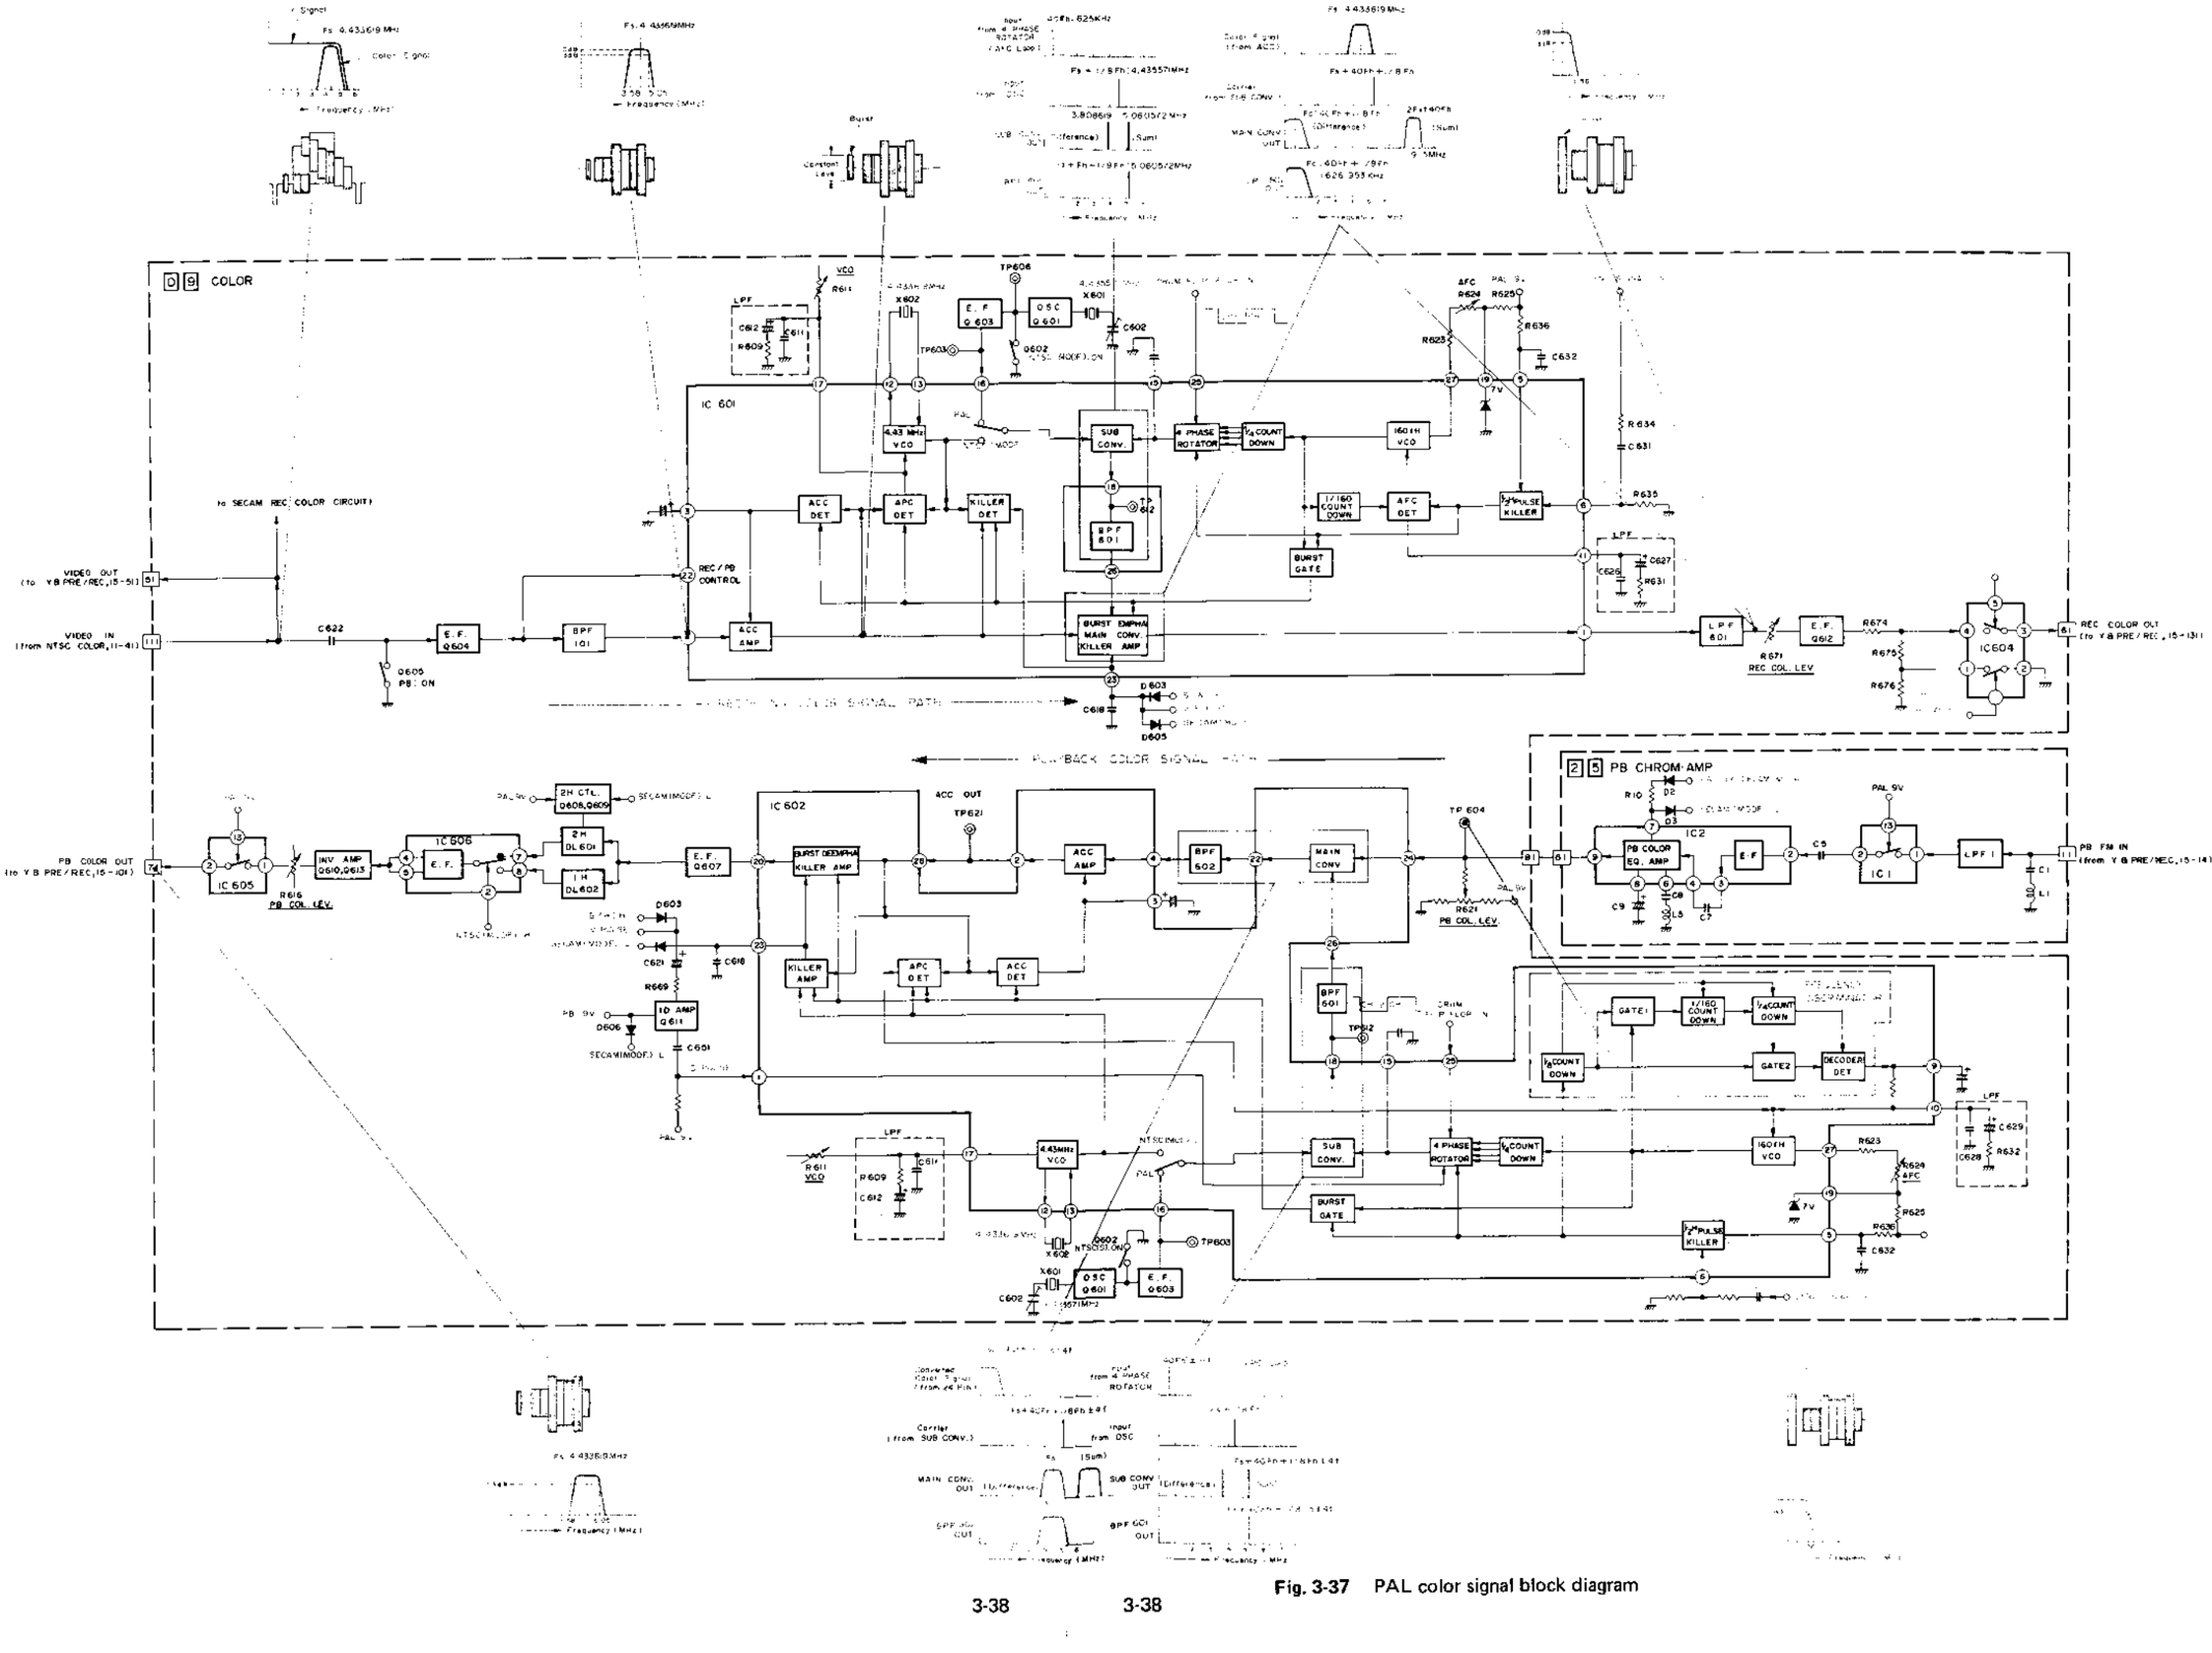

Fig. 3-37 PAL color signal block diagram

3.3.5 PAL color signal system

The main circuits functions in the PAL color signal system are the same as those in the NTSC system. Therefore, only the differing points are outlined below.

1. The down converted subcarrier frequency is selected for (40 + 1/8) Fh, and oscillators are contained for Fs and Fs + 1/8 Fh (4.433619 MHz and 4.435572 MHz, respectively).

   The Fs oscillator output is employed by the color killer and APC circuits. The Fs + 1/8 Fh oscillator is required in order to obtain the (40 + 1/8) Fh down converted subcarrier frequency. Frequency spectra of the various components are indicated in Fig. 3-38.

2. During recording, the phase of only the CH-2 track color carrier signal is shifted –90° every 1H. The drum flip-flop signal is employed for distinguishing between the CH-1 and CH-2 tracks.

   When potential between 0 and 1.0 V appears at pin 25 of IC201, CH-1 is determined and the 40 Fh phase is shifted +90°. Appearance of between 2.5 and 5.5 V signifies CH-2, and the 40 Fh phase is shifted –90° every 1H. When the input current is between 0.97 and 1.50 mA, the phase is not shifted. Drum flipflop switching is performed by IC603.

   During playback, the VCO frequency is 4.43 MHz, while the color carrier frequency for NTSC (modified is 4.43 MHz) and NTSC (standard) is 3.58 MHz.

   In SECAM (modified) operation, the color carrier frequency is simply converted to lowband and recorded, using the PAL system converter circuit, and without countdown.

   In the playback mode, field correlation of the recorded tape pattern is utilized for reducing crosstalk. At this time, Q609 is off and Q608 on, cutting off the 2H delay line circuit.

3. SECAM detector

   As described earlier, the color signal circuit of this model is basically designed for recording a PAL color TV signal. A down converted, phase shifted direct recording system is used for PAL.

   Models specifically designed for SECAM generally employ a 1/4 countdown direct recording system. However, this model records the SECAM signal by using the down converted system.

   In this process, the SECAM signal is frequency modulated and sent through a bell filter. Since no effect is imparted on the phase error, the phase shift system for PAL recording becomes meaningless, and the signal is simply converted to lowband and recorded.

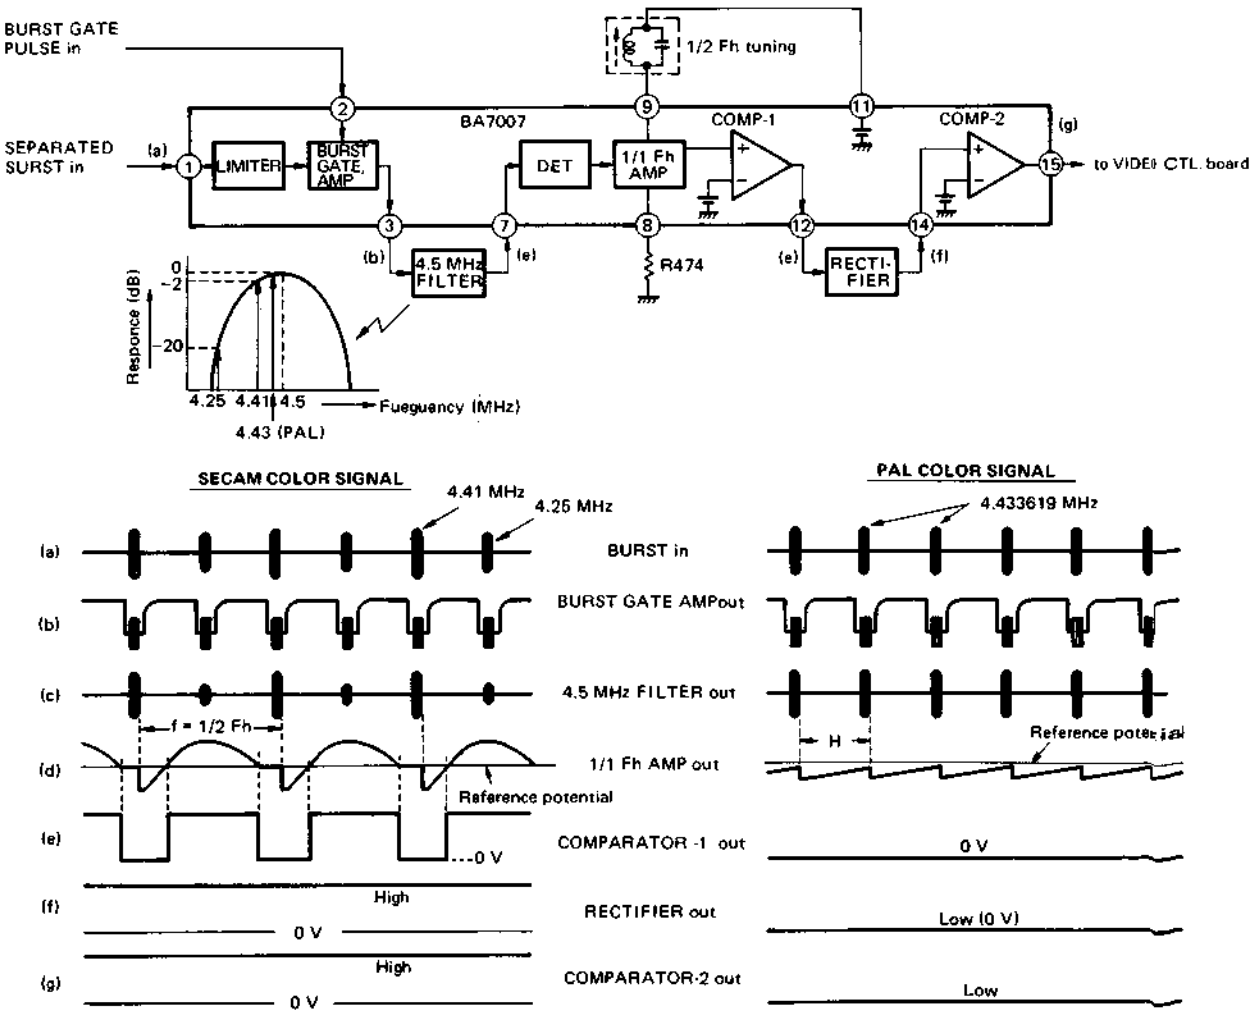

Fig. 3-38 SECAM detector

Line correction in the tape pattern reduces crosstalk during playback and the 2 H delay line system for PAL is not employed. The SECAM detector circuit distinguishes between PAL and SECAM signals. With a SECAM signal, the phase shift and 2 H delay line circuit are cutoff.

Refer to the block diagram of Fig. 3-38.

During both recording and playback, the burst signal sampled by burst gate is sent from pin 1 to BA7007 limiter. The SECAM burst signal alternates every line between 282 Fh (4.40625 MHz) and 272 Fh (4.25 MHz) and after passing through the bell filter, the resulting burst level is not fixed. For this reason, the limiter shapes the waveform to produce a fixed level square-wave, which goes to the burst gate amplifier.

The burst gate pulse is supplied to BA7007 pin 1. This circuit removes components other than the burst which were amplified by the limiter. This output goes to the 4.5 MHz filter as waveform (b). The filter possesses the response indicated in the block diagram and passes the 282 Fh burst component, while attenuating the 272 Fh component. Waveform (c) illustrates the filter output.

Consequently, 4.5 MHz filter enhances the 282 Fh and attenuates the 272 Fh. The result is integrated by DET and the 1/2 Fh output is supplied to the 1/2 Fh amplifier.

The 1/2 Fh component is amplified and the Fh component attenuated by the L414, 1/2 Fh tuning circuit to produce waveform (d). This output is supplied to the comparator-1 non-invert input. The constant potential is supplied to the invert input as a reference signal for the comparator.
At this time, when the voltage at the non-invert input from the 1/2 Fh amplifier exceeds the reference voltage (about 6 V), the comparator-1 high output goes from pin 12 to the rectifier. When below the reference voltage, the comparator output becomes a low potential. Waveform (e) illustrates the comparator-1 output. This is fullwave rectified by CR to yield waveform (f). The rectifier high output is supplied to the comparator-2 to yield waveform (g).

When a PAL signal is received, the burst frequency becomes fixed at 4.433619 MHz every line. At this time, detector output is Fh, the 7.5 kHz amplifier output becomes a low potential.

In the case of SECAM recording, output is low, which goes via D403 to IC402 rotation control circuit. The 25 Hz drum flipflop signal becomes dropped to ground potential, defeating the phase shift circuit of the CH-2 head component.

During playback, the phase shift circuit is defeated by setting electronic Q609 off and Q608 on, preventing supply of the 2 H delay line output to the mixer. Only the bypass output from Ra goes to the mixer, thus avoiding adverse effects on the SECAM color FM signal due to mixing.

3.3.6 SECAM color signal system

Refer to the block diagram of Fig. 3-39.

1. Recording system

The color TV signal selected by the input select switch is applied to BPF501 for obtaining the color FM signal with central energy at the subcarrier (Fcr = 4.40625 MHz; Fcb = 4.25 MHz), which goes to IC501 AMP and DIF EQ AMP. Prior to BPF501, equalizer EQ501 delays the color component by about 400 nanoseconds (400 x 10^{-9} sec) to match the timing of the luminance signal on the recorded tape pattern.

DIF EQ AMP possesses characteristics similar to an bell filter and converts the anti-bell curve used during transmission to a flat energy distribution in preparation for 1/4 frequency countdown. The limiter circuit ensures correct countdown of the color FM signal from DIF EQ AMP.

From REC LIMITER, the limited signal goes to the 1/4 countdown circuit of IC501. This IC contains two D-flipflop stages by which the signal is counted down 1/2 at each stage to result in 1/4 countdown. The color FM carrier band is converted from 3.9 to 4.75 MHz to a range of 0.98 to 1.19 MHz, then supplied via IC501 pin 16 to BPF502.

For mixing with the highband FM luminance signal, BPF502 limits the upper range of the counted down color signal sideband, while the lower sideband range is limited in order to improve S/N and avoid color reversal during playback. The high sideband is limited to approximately 300 kHz and the lower sideband to about 600 kHz.
This output is amplified by IC501 pin 23 and pin 24 and sent to IC501 pin 25.

At the next stage, DIF EQ AMP possesses characteristics approximating those of an anti-bell filter with a center of 1.07 MHz (1/4 x 4.286 MHz). The unmodulated carrier component is attenuated and the design serves to improve S/N and avoid color reversal during recording and playback.

Electronic switch SW-4 serves to cut horizontal and vertical sync noise from the recording colorsignal. With the SECAM signal, the subcarrier is inserted in the H blanking period and the color identification signal in the V blanking interval. If noise is present it could interfere with detection of the subcarrier and identification signals at the TV receiver. Also, if the noise level is high, it could become mixed with the FM luminance signal and disrupt synchronization during playback. The noise component is therefore cut.

The noise arises in the H and V sync signals in the following manner. BPF501 attenuates the lowband luminance component of the input video signal, however, harmonics from the rapid rise and fall components of the sync signal cannot be completely removed. This leakage becomes amplified by the limiter and after countdown and delay, it appears as noise in the H and V sync components.

After cutting the noise, the color signal is sent to IC604 pin 8, then R545 (REC COLOR LEVEL) adjusts the color signal recording current.

As mentioned previously, a color killer circuit is not included in the color signal recording system. When the rear panel mode switch is set to COLOR, the circuit functions are not altered.
When set to B/W, low potential via conn. 155 goes through D502 to IC501. This cuts off color signal supply to REC AMP-1 and REC AMP-2.

2. Playback system

In the color playback system, bandpass filter BPF502 attenuates the luminance signal and passes the 1/4 counted down color signal.

Amplifier IC501 amplifies the counted down color signal from BPF502 and supplies it to the equalizer amplifier. The resonance circuit of L502 possesses nearly the opposite characteristics as the recording DIF EQ AMP.

At IC501 pin 12 and pin 18, limiter and doubler circuits convert the FM carrier frequency from the range of 0.98 to 1.19 MHz to the range of 1.95 to 2.38 MHz, which appears at pin 8. IC501 operates in the same manner as the demodulator circuit described in section 3.3.2 - 5.

The high sideband component, attenuated by BPF502 during recording in order to improve S/N and prevent color reversal, is reproduced by applying about 40 dB limiting.

The 1.95 to 2.38 MHz FM carrier and both sideband components from IC501 pin 8 go to BPF503, which attenuates the carrier fundamental component. At the same time, both sideband components are passed and supplied to the doubler circuit of IC501 pin 7.

This IC operates in the same manner as IC501 pin 8, pin 12 to again double the frequency.

After returning the FM carrier to the original range of 3.9 to 4.75 MHz, the color FM signal is supplied to HPF401. In the same manner as during recording, SW-5 prior to HPF501 cuts H and V sync noise which has become amplified by the limiter. By providing this circuit prior to HPF501, switching noise can be removed from the final output.

HPF501 removes the fundamental carrier leak component from the IC501 doubler output. DIF EQ AMP attenuates the luminance signal area for mixing with the demodulated lowband AM luminance signal and limits the color FM signal sidebands to about ±1 MHz, then supplies the signal to AMP-3.

DIF EQ AMP possesses characteristics very similar to an anti-bell filter. The unmodulated carrier component is attenuated and an anti-bell response imparted to yield the equivalent of the transmitted signal. R543 (PROCESSED COL. LEVEL) adjusts the output level. Mixing with the PB luminance signal is performed at IC106 to produce the video output signal. Remaining operations are the same as for the luminance signal playback system.

Although a playback color killer circuit is absent, setting the mode select switch to B/W supplies low potential via D502 to the IC501 pin 20. This turns on SW-5 and prevents PB color signal supply to subsequent circuits. Only the luminance signal is obtained at the output.

3-41

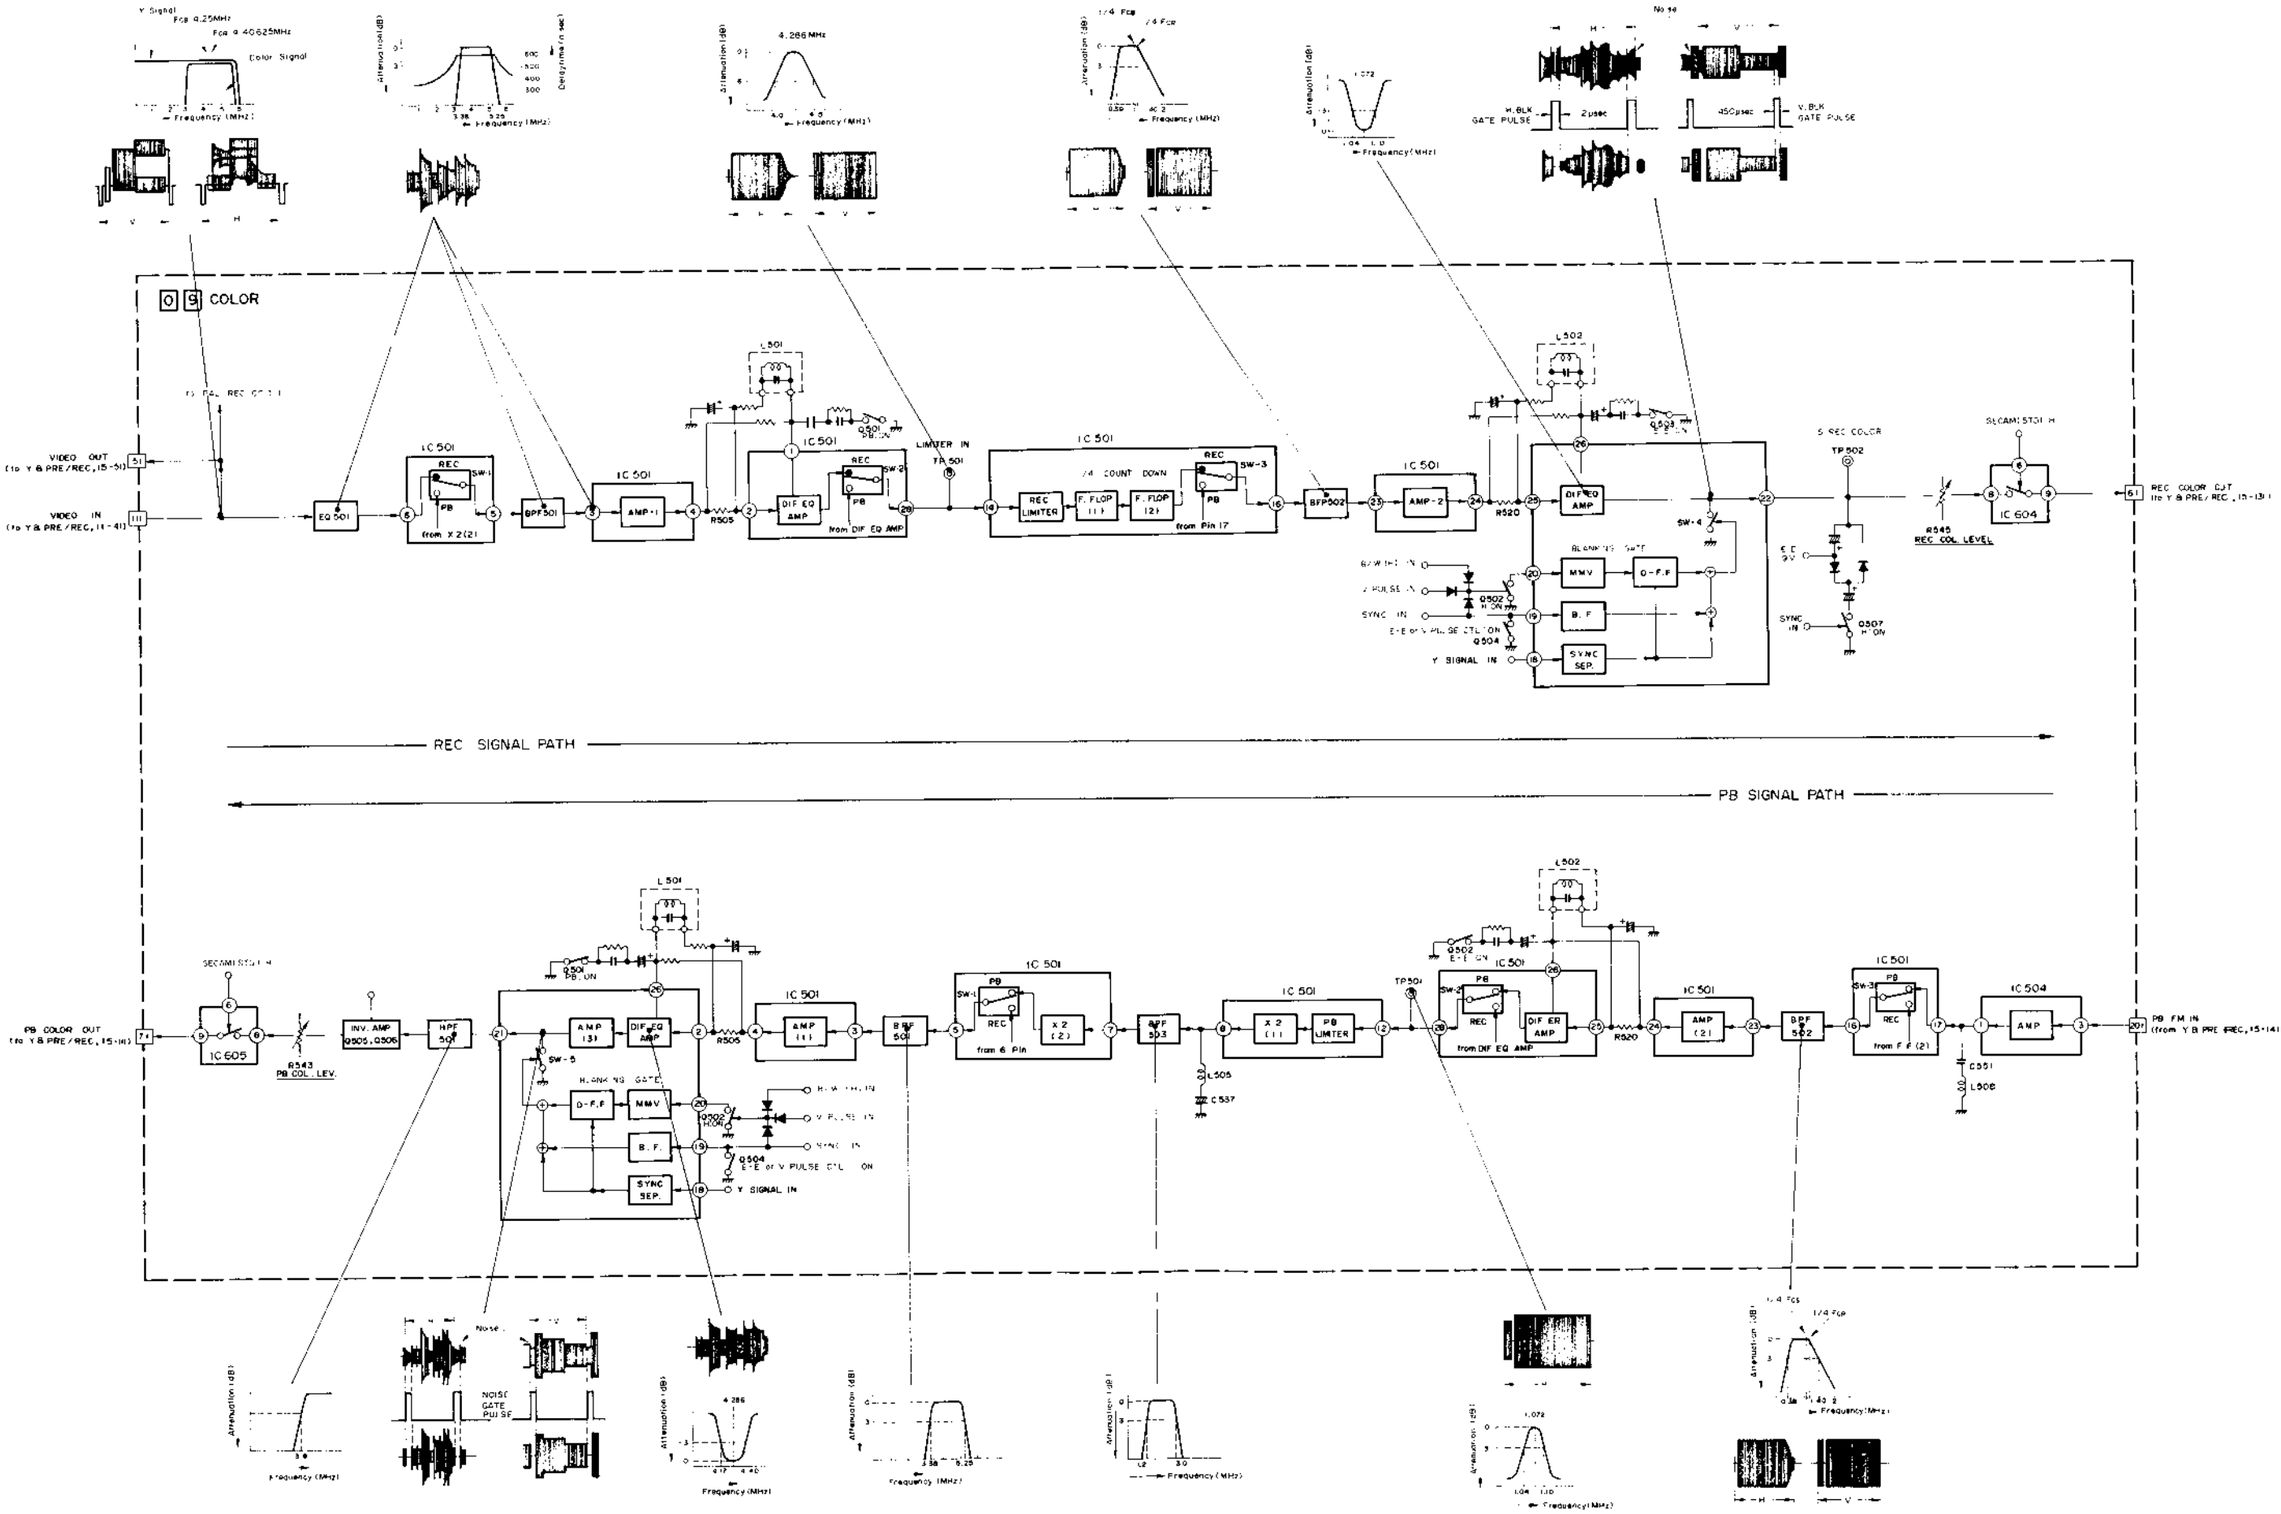

Fig. 3-39 SECAM color signal block diagram

3.4 AUDIO SYSTEM

3.4.1 General

Although the magnetic tape pattern of the VHS format is sufficiently flexible to allow use with two track audio systems, this particular model is designed for monophonic audio recording and playback.

For audio signal inputs are provided:
1) TUNER audio input from the built-in tuner,
2) AUX audio input from the rear panel 5-pin DIN socket,
3) CAMERA audio input from the 10-pin camera connector, and
4) Microphone input via the MIC jack.

When a microphone is not connected, the REC SELECT switch selects AUX, TUNER and CAMERA input signals for recording.

With this model, the microphone input can be mixed with another input signal selected by the REC SELECT switch.

Audio outputs are also provided in four lines, as follows:
1) Through conn. 52 to the RF converter,
2) Via conn. 42 to the rear panel 5-pin DIN socket,
3) To the headphone jack through conn. 11, and
4) Via conn. 61 and conn. 63 to the CAMERA connector.

Conn. 63 is an input during recording and an output during playback.

3.4.2 Block diagram description

Refer to the block diagram of Fig. 3-40.

1. Recording system

The TV sound signal selected by the built-in tuner goes to conn. 31 and appears at −14 dBs level at SW-1. An auxiliary audio input from the rear panel 5-pin DIN socket is supplied via conn. 44 to SW-2 at −20 dBs level. A camera audio input at the CAMERA connector is sent through conn. 63 to SW-3 at −20 dBs level.

A microphone input signal goes via conn. 72 to IC2 pin 14. The mic amp increases the level by about 40 dBs. In absence of a microphone connection, Q1 switches on to cutoff the mic amp output to prevent influence on the signal to noise ratio.

The signals from SW-1, SW-2, SW-3 and the mic amplifier are mixed at R31, R32 and R33, and supplied to IC2 pin 12 (REC LINE AMP). Through SW-4 within the IC, the signal appears at TP31 (LINE AMP OUT). Frequency response of the recording line amplifier is indicated in the block diagram.

Amplifier A of IC3 amplifies the signal from SW-4 approximately 12 dBs and supplies it to the lowpass filter (LPF). As shown in the block diagram, this filter passes frequencies below 12 kHz and attenuates higher frequencies. Its purpose is mainly to prevent the 15.625 kHz video component from affecting the Dolby* NR circuit.

From the LPF, the signal is amplified approximately 18 dBs by amplifier B of IC3, then branched to the E-E and recording systems. (The E-E system is outlined in the Playback System description.)

*Noise reduction system manufactured under license from Dolby Laboratories Licensing Corporation.
Dolby and the double-D symbol are trademarks of Dolby Laboratories Licensing Corporation.

Amplifier B output is supplied to circuit EK of IC3 for encoding in the Dolby-B format. If the DOLBY NR switch is set to OFF, circuit EK functions simply as an amplifier and does not perform encoding.

The signal from EK goes to IC4 pin 5 (REC AMP). The approximately 12 kHz peak of the recording amplifier is determined by the constant of L2, R100 and C55.

Electronic switch Q12 is off in the recording mode. From the recording amplifier, the equalized audio signal is sent through the audio bias trap composed of L5 and C71, mixed with bias from C66, then applied via conn. 81 to the audio head.

During recording, electronic switch Q16 is on and the bias oscillator of Q17, Q18 and T1 operates. This output becomes the audio bias through C66 that is mixed with the audio signal.

Electronic switches Q6 to Q9 are cutoff in the recording mode.

2. Playback system

The playback signal from the audio head goes at approximately −68 dBs level via conn. 83 to IC2 pin 2 (PRE AMP). Electronic switches Q6 to Q9 are on during playback and conn. 81 is grounded. Q10 is off in the playback mode, but on during recording (at which time conn. 83 is grounded).

The block diagram shows the frequency response of the preamplifier and this is determined by the playback equalizer composed of C28, R65 and R66. Through the playback line amplifier and SW-4, the signal is amplified about 14 dBs and sent to IC3 pin 4 (amplifier A).

In the same manner as for recording, the signal goes through the LPF, amplifier A and circuit EK to IC3 pin 9. Via SW-5, the output appears at IC3 pin 8 (TP4). The frequency response at TP14 is shown in the block diagram. During the muting function (slow and still modes), electronic switch Q11 switches on to cutoff the audio signal.

The TP14 (MONITOR OUT) signal is supplied to IC4 pin 3 (OUTPUT AMP), where it is amplified approximately 7 dBs and obtained at IC4 pin 1.

From this point, the signal is sent to the following four outputs.

1) From conn. 52 at 0 dBs to the RF converter,
2) From conn. 42 at −6 dBs to the 5-pin DIN socket,
3) From conn. 11 at −32 dBs (8 Ω load) to the headphone jack, and
4) From conns. 61 and 63 at −6 dBs to the camera connector.

E-E line

Without going through circuit EK, the signal from IC3 pin 6 (amplifier B) proceeds via SW-5 to IC3 pin 8 (TP14). This is amplified and sent from IC4 pin 3 (OUTPUT AMP) to the four output lines.

In addition, one output of IC4 is supplied to the AGC amplifier composed of D1, D2, Q3 and Q4. This circuit automatically controls the gain only in the recording and E-E modes. As can be noted from the input/output response indicated in the block diagram, attenuation is linear with an input below −20 dBs. Above −20 dBs, the AGC circuit functions to maintain an approximately 2 dBs output.

Electronic switch Q2 is on during playback, discharging C22 and grounding D1 and D2 (DET) output. This prevents leakage from the input signal lines during playback.

3. Cue signal and audio dubbing systems

1) Cue signal

The cue signal is a 30 Hz squarewave supplied to the full erase head for about one second when the recording mode is initially entered, at which time it becomes recorded on the tape. However, the cue signal is not recorded at the transition between the pause and recording modes.

During playback the cue head (mounted on the tension pole) picks up the cue signal and if the SEARCH switch is set to CUE, this signal functions as the auto stop signal.

Low potential from the mechacon circuit is applied via conn. 91 to D7 cathode and Q13 base. Q13 switches on to supply 22 V DC to IC5 pin 3. Consequently, the cue signal becomes obtained from IC5 pin 6. It is amplified by Q14 and Q15, and supplied to pin 9 of relay RY-1. D7 switches on, switching the relay on and shorting pins 9 and 13. The cue signal then goes via conn. 104 to the full erase head.

Approximately one second later, conn. 91 returns to high potential, which cuts off Q13 and stops the cue oscillator. At the same time, D7 cuts off and the relay becomes cutoff.

2) Audio dubbing system

Low potential appears at conn. 96 during the audio dubbing mode. Diode D8 and the relay switch on, thus inhibiting the full erase head. However, since the full erase head also functions as load for the bias oscillator, in order to prevent recording current variation, L4 becomes connected as a dummy load.

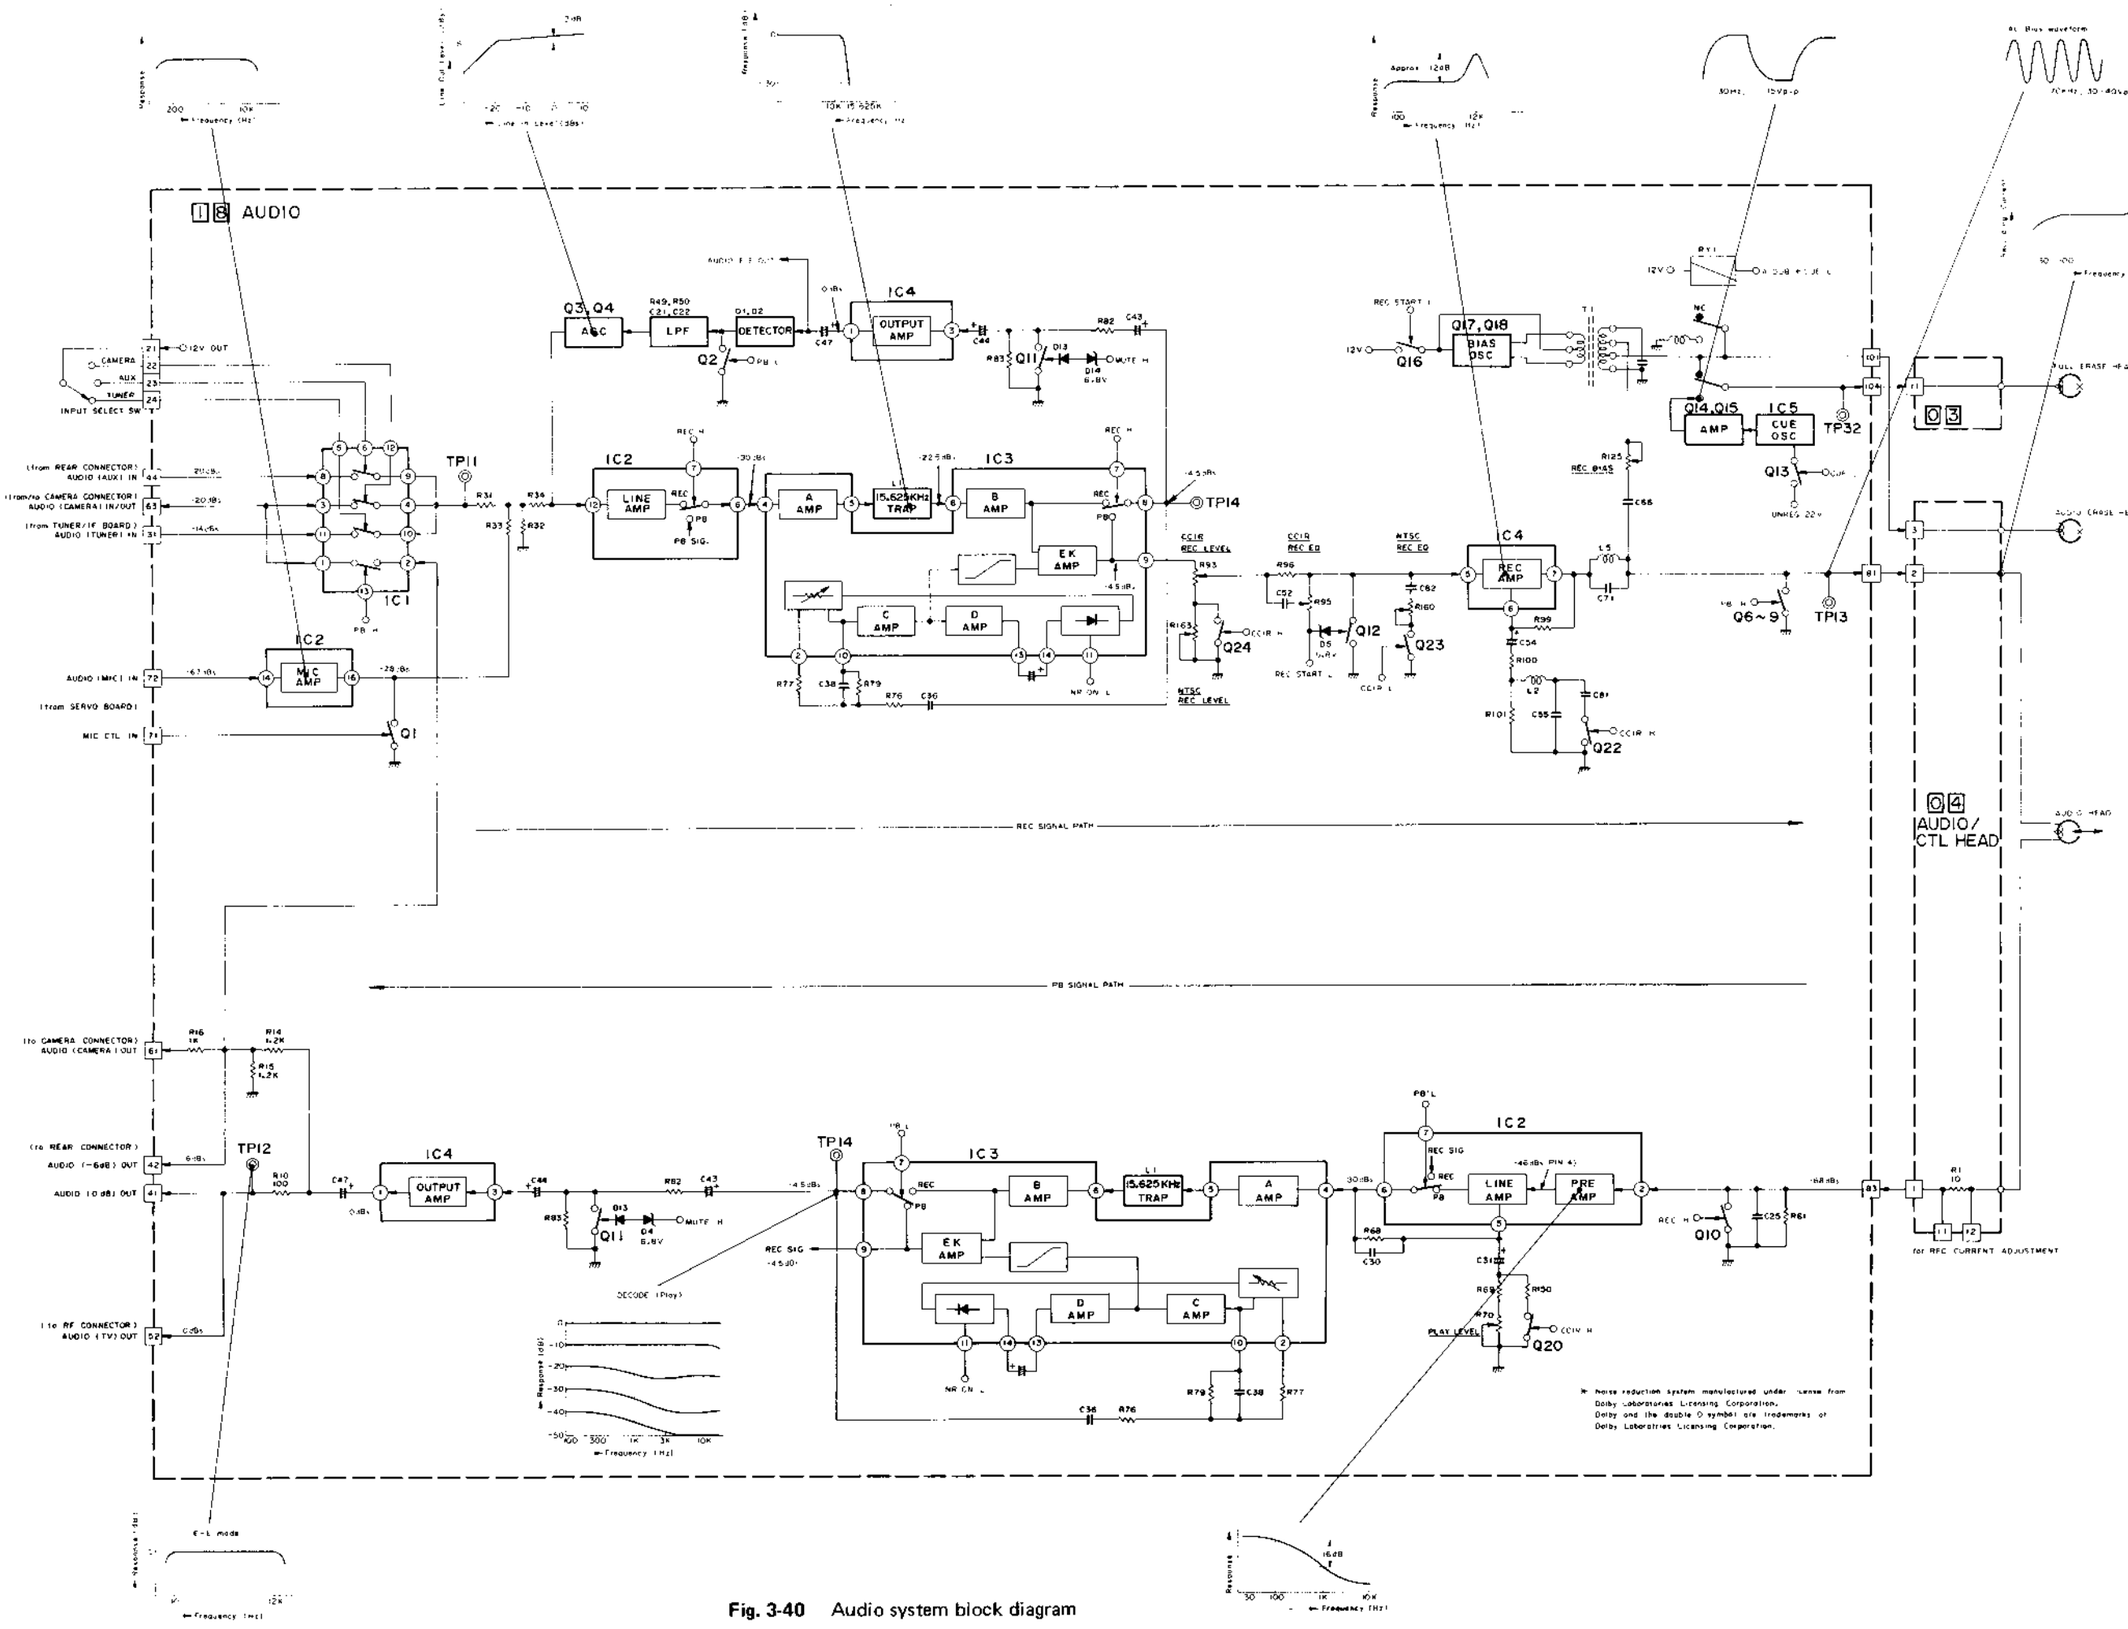

Fig. 3-40 Audio system block diagram

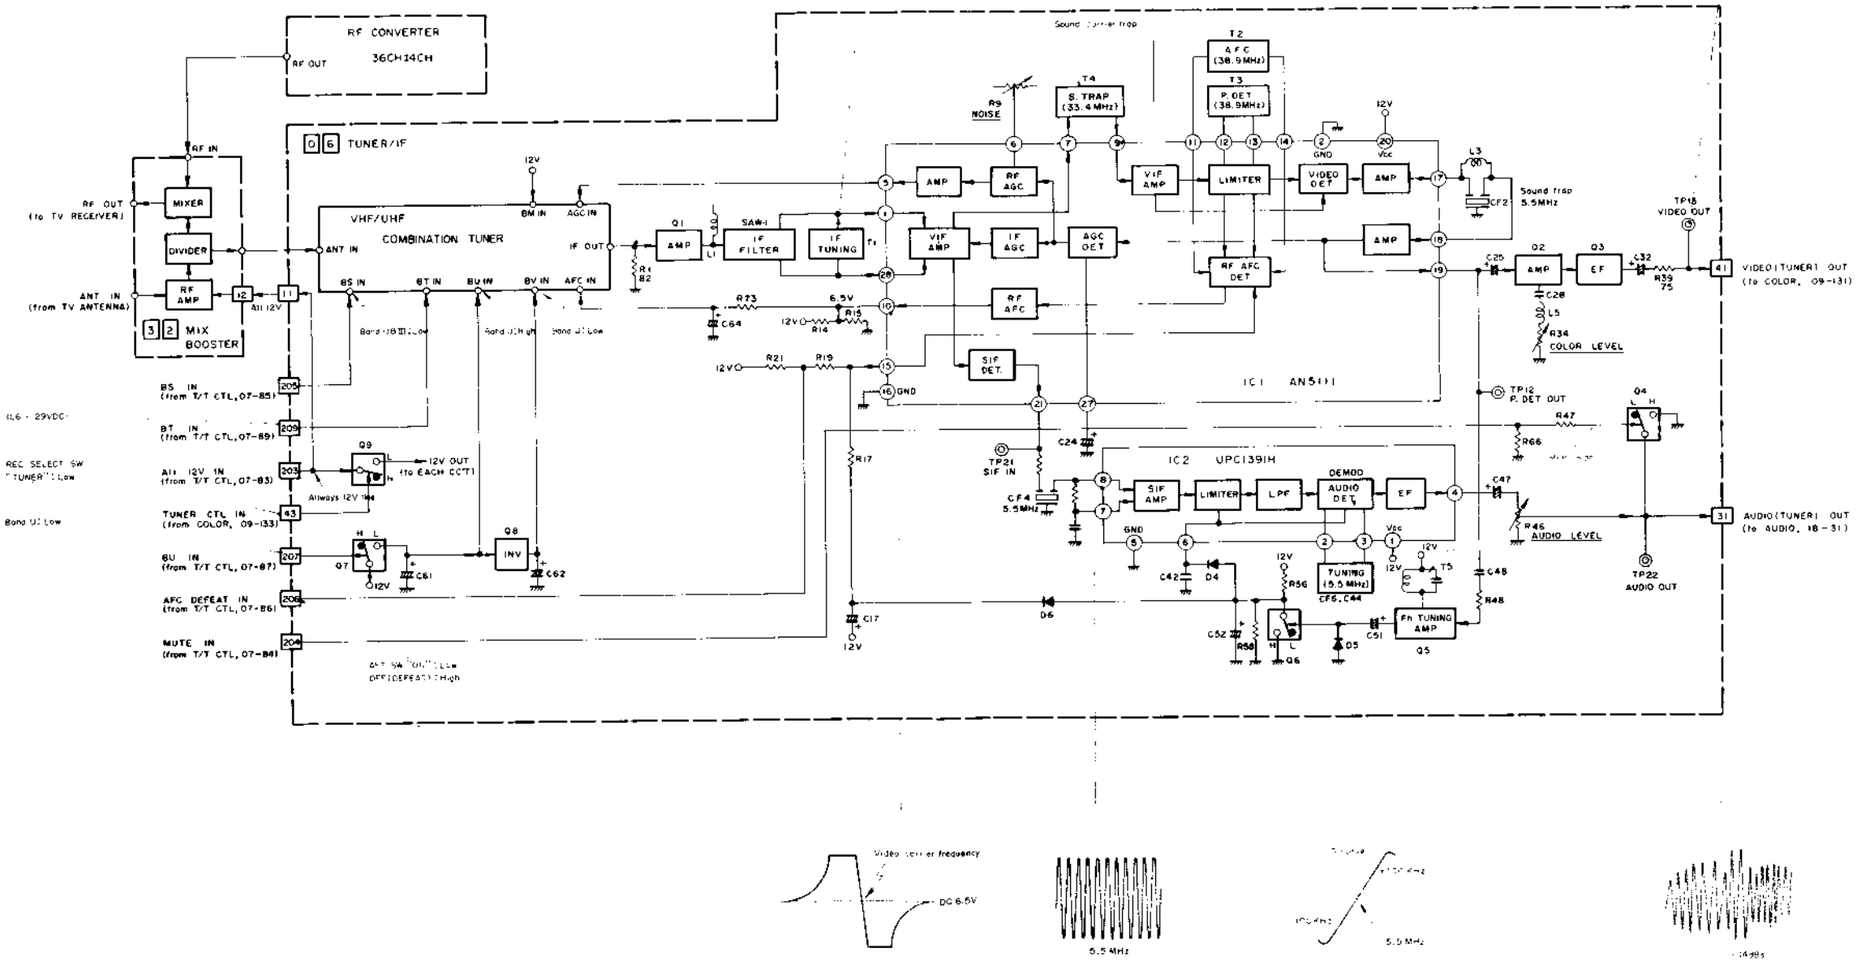

Fig. 3-41 Tuner/IF block diagram

3-46

3.5 TUNER/IF CIRCUIT

3.5.1 General

This model incorporates a combination VHF/UHF tuner. The band select switch (Tuner/Timer Control board) selects from among three positions of I (VHF channels 2 to 4), III (VHF channels 5 to 12) and U (UHF channels 21 to 69).

Preset tuning is performed by using a single tuning control and a voltage synthesizer system. These functions are controlled by voltages from the T/T CTL circuit.

Refer to the tuner/IF block diagram of Fig. 3-40.

3.5.2 Circuit description

1. Video detector circuit

Broadcast television signals are supplied to the antenna input (ANT IN) of the mix booster, from which the RF amplifier amplifies only the portion subject to loss at the next stage divider. One output of the divider is mixed with the CH-36 RF signal from the RF converter and supplied via the RF OUT terminals to the connected TV receiver.

Another output of the divider goes to the ANT IN connection of the tuner.

When the REC SELECT switch is set to TUNER in the recording or E-E mode, low potential at conn. 43 (TUNER CTL IN) switches Q9 on to supply 12 V to the circuits. In the playback mode, high at conn. 43 inhibits tuner/IF operation.

So long as the rear panel main power switch is on and the unit is connected to a live AC power source, 12 V DC at conn. 203 (ALL 12 V IN) is supplied to both Q9 and the mix booster. When the CH PRESET switch is on, the T/T CTL circuit supplies approximately 0.7 V DC for bands III and U, and 30 V DC for band I to conn. 205 (BS IN).

The T/T CTL circuit also sends low potential to conn. 207 (BU IN) for band U and high potential for bands I and III. Since Q8 is an inverter, when band U is off, low potential becomes sent to BV IN.

As noted above, conns. 205 and 207 are band select input terminals. The band select output voltages become as indicated in Table 3-5.

BAND	BS IN	BU IN	BV IN
U	less than 0.8 V	more than 11.5 V	less than 0.8 V
III	less than 0.8 V	less than 0.8 V	more than 11.5 V
I	more than 30 V	less than 0.8 V	more than 11.5 V

Table 3-5 Band select output voltages

Regardless of the band, when the tuning control is turned fully counter-clockwise, 0.6 V DC is supplied to conn. 209 (BT IN). At the fully clockwise position, this becomes 29 V DC. In other words, the tuning control varies the tuning voltage in the range from 0.6 to 29 V DC.

As a result, the selected channel TV signal is converted to an intermediate frequency which appears at TUNER IF OUT at 75 Ω impedance.

The video carrier frequency of the IF signal from the tuner is 38.9 MHz.
At the same time, the difference between video and sound carrier frequencies is 5.5 MHz.

R1 adjusts the impedance of the IF signal from the tuner, which is then amplified and applied to the IF filter.

SAW-1 of the IF filter is a surface acoustic wave resonator, which features a single resonance point without the need for a tuning circuit and low spurious signal production. Since SAW-1 output tends to attenuate the adjacent bands, L1 and T1 compensate for the low and high bands to yield the response indicated in the block diagram.

The output goes to pins 1 and 28 of IC1 VIF amplifier. The 3 stage differential amplifier output of the video IF amp goes from pin 7 to again enter the IC at pin 9. Sound trap T4 between pins 7 and 9 is a sound carrier trap. Via pin 9, the video IF signal is sent to the video detector stage.

A differential amplifier is used by the sync detector type video detector. The VIF amplifier increases the signal to an adequate level for driving the detector, then supplies two outputs at opposite phase to the video detector. Through the limiter, the signal is fullwave rectified in a double balanced connection to become the detector output.

Transformer T3 connected to the limiter resonates at the video carrier frequency and applies a precise same phase input waveform to the video detector. The video detector output is amplified and obtained as a positive polarity video signal from pin 17.

Through audio trap CF2 (5.5 MHz), the signal is amplified and inverted at pin 18 and obtained from pin 19. Q2 inverts and amplifies the signal and an emitter-follower converts its impedance. C32 cuts the DC component and the resulting positive (TUNER) video signal goes via conn. 41 to the color board.

R34 (COLOR LEVEL) adjusts the color level at the L5 & C28 subcarrier frequency resonance circuit of Q2 amplifier.

2. RF AFC circuit

The RF AFC (automatic frequency control) detector functions in the same manner as the video detector. The two limiter signals at 90° phase relationship are applied to this circuit to produce the output. T2 of the RF AFC detector and T3 of the picture detector are connected to adjacent pins of IC1, producing a capacitance coupling effect equivalent to 1 to 2 pF.

At the time of video carrier frequency resonation, 90° phase difference is produced in the inputs from the limiter and the RF detector output becomes zero. The phase difference fluctuates according to the deviation from the resonance frequency. As indicated in the block diagram, by detecting the phase, the RF AFC output is obtained with positive and negative variation centered on the video carrier frequency. This output goes via pin 10 to the tuner AFC input and controls the local oscillator frequency.

When the AFT (automatic fine tuning) switch of the T/T CTL board is on, low potential goes to the RF AFC detector, which then operates as described above.
If the AFT switch is OFF, 12 V via R21 through pin 15 cuts off the RF AFC output.
At this time, the high impedance of R14 and R15 supplies fixed 6.5 V to the tuner AFC.

3. AGC circuit

The reverse polarity video level forms the AGC (automatic gain control) detector input at IC1 pin 19. One detector output goes through the IF AGC circuit and controls the equivalent emitter resistance at the first stage of the VIF two stage differential amplifier.

The other AGC detector output is sent to the RF AGC and amplifier circuits, then via pin 5 to the tuner AGC input, where it controls the gain of the tuner output. R9 (NOISE) at pin 6 adjusts for minimum noise in the output with respect to the level at the antenna input.

4. Audio detector circuit

An intercarrier system is used by which the video and sound carriers produce an FM beat signal that becomes the second audio IF signal. The output of the video IF amplifier goes to the sound IF detector. Detection is performed by using the diode function between the base and emitter of the SIF amplifier transistor.

The 5.5 MHz component is obtained at pin 21. Ceramic filter CF4 selects only that frequency component, which then goes to pins 7 and 8 of IC2. The signal is amplified by the SIF amplifier and sent through the limiter and lowpass filter circuits to the FM audio detector.

CF6 and C44 form a tuning circuit between pins 2 and 3 for producing the "S" curve requird for driving the differential amplifier type FM detector. Consequently, amplitude variations in accordance with frequency deviation appear at opposite polarity at pins 2 and 3, forming an "s" curve as indicated in the block diagram. This is fullwave rectified and obtained through an emitter-follower.

C47 cuts the DC component of the IC2 pin 4 output and R46 (AUDIO LEVEL) adjusts the level, after which the signal goes via conn. 31 to the audio board as the audio (TUNER) signal.

When mute high potential from the T/T CTL board appears at conn. 204, Q4 switches on, grounding the audio output. This operation is performed during channel select.

5. Audio muting

This circuit detects the horizontal sync signal and functions to prevent audio noise when the video output is not precisely tuned.

R48 and C48 form a highpass filter which attenuates the video component of the reverse polarity signal from IC1 pin 19. The Fh (15.625 kHz) tuning amplifier of Q5 and T5 yields the horizontal sync signal. C51 cuts the DC component and D5 clamps the positive sync tip to zero potential. Q6 switches on and off with the horizontal sync signal.

Electronic switch Q6 is off only at the sync tip and on at other times due to high potential. Consequently, the charging time of C52 from 12 V through R56 is much shorter than the discharge time through R58. D4 becomes cutoff and IC2 normally operates.

However, when tuning deviates, the horizontal sync signal is not obtained. This completely cuts off Q6 and C52 charges to saturation. The resulting high output goes via D4 to IC2 pin 6, cutting off the limiter and audio detector circuits of IC2 and preventing the audio output.

3.6 TUNER/TIMER CONTROL AND DISPLAY CIRCUIT

3.6.1 Introduction

This machine uses a voltage synthesizer tuning system with a single preset VR. In this system, the tuning voltage is converted into a digital value and stored in a ROM. The data corresponding to the selected channel is converted into an analog signal which is in turn sent to the tuner/IF board.

The timer permits setting of 8 programs up to 2 weeks in advance. The recording length can be set up to 395 minutes in 5-minute increments. Moreover, the timer permits setting of recording date, channel and start time.

This sytem consists of IC206 MB8851AM-143L (timer control), IC207 UPD552C-088 (tuner control) and IC401 UPD552C-079 (display driver).

3.6.2 Circuit description - 1

1. Tuning circuit

Both the HR-7700 and HR-7600 employ a voltage synthesizer system for the tuning section. However, in contrast to the completely automatic system of the HR-7700, the HR-7600 system uses a preset control. Some users find this latter method easier to employ, while the simplified circuit provides an advantage from a servicing point of view.

Refer to the block and schematic diagrams. The HR-7600 uses the μPD552C for tuner control, which possesses a lower memory capacity than the μPD553C employed for the HR-7700. Also, in the HR-7600 system, tuning system performance depands to a large degree on the preset control voltage detection error during preset.

At the DC comparator, the voltage set by the PRESET control and the DC voltage from a digital to analog converter (DAC) are compared. The accuracy of this detection is an important factor in determing tuner performance. A microcomputer program was developed for the HR-7600 to maintain the voltage detection error during tuning at less than 4 mV. Refer to the microcomputer flowchart.

The PRESET switch is set to ON when performing channel preset. At this time, the microcomputer instructs the DAC (IC202) to produce a pulse width corresponding to 15 VDC. This is equivalent to 1/2 the output of the DAC internal 12 bit counter. This counter increments in steps from 1 to 4096 to vary the tuning DC voltage in 7 mV steps from 0 to 30 V. By first setting the counter to 2048, the DAC output becomes 15 VDC. Consequently, the DAC counter becomes set to:

1000 0000 0000

A lowpass filter (LPF) delays the output 50 msec and the DC comparator output is polled.

At this time, if the DAC output is higher than the preset DC value, the CPU instructs the DAC to reduce the voltage. Conversely, if the voltage is lower, a higher output is instructed.

From the IC207 pin 3 output at part C3, the CPU detects whether the DAC voltage is higher or lower than the preset voltage. At this time, the relationship among the CPU input, DAC out put and PRESET control becomes as follows.

*If the 15 V DC DAC output is higher than the preset value:

Low potential appears at IC207 pin 3	→ CPU issues 1.85 V "DOWN" command to DAC
	↓
1000 0000 0000 When 15 V DC	Upper 4 bits of DAC counter decrement by 1.85 V
↓	
1.85 V DC down	↓
↓	
0111 0000 0000 15 V – 1.85 V	After 16 msec delay, DC comparator is again sampled.

*If the 15 V DC DAC output is lower than the preset value:

High potential appears at IC207 pin 3	→ CPU issues 1.85 V "UP" command to DAC
	↓
1000 0000 0000 When 15 V DC	Upper 4 bits of DAC counter increment by 1.85 V
↓	
1.85 V DC up	↓
↓	
1001 0000 0000 15 + 1.85 V	After 16 msec delay, DC comparator is again sampled.

The CPU controls the upper 4 bits of the DAC internal 12 bit counter. The tuning voltage becomes divided into 16 steps of 1.85 V each for varying the DAC output. This allows the DAC output to quickly follow any position of the PRESET control.

In practice, although the DAC counter is incremented one step at a time if its output is less than the PRESET control value, if a greater value is detected, the CPU issues a 2 step "POWN" instruction. This is to compensate for the delaying action of the lowpass filter circuit between CPU ports C and E. Thus, the down instruction becomes: 1.85 x 2 steps = 3.75 V.

The CPU next sets the internal counter to 8 and polls the band data input. These data are detected from the lower two bits of the 16 bit channel data, as indicated in Fig. 3-42.

CPU ports C0, C2 and C3 detect the BAND switch state and accordingly issue the two bit data. After band selection, the CHANNEL SET LED lights and the skip settings are detected. In the case of a skipped channel, low potential appears at CPU ports C0, C2 and C3. In absence of skip, DAC less than VR status is checked.

Fine adjustment is then performed in 15 mV per step. This selects the lower 2 bits of the 12 bit counter. The DAC output continues to increase at 15 mV per step and at the point the value exceeds the VR setting, the internal counter decrements one count. This operaiton repeats 8 times until the internal counter reaches 0. After 8 repetitions of this process, the DC output of the DAC is brought to within the range of ±4 mV of the PRESET control value.

In this state, the CPU waits for pressing of the STORE button, at which time, the DAC voltage is checked for a value in the range of ±120 mV of the VR setting potential. The program counter is set to 8 and DAC less than VR status is checked. If less, the DAC +2 mV instruction is issued.

However, the 12 bit DAC counter possesses a maximum resolution of 4096 steps at 7.3 mV per step. Threfore, when the STORE button is pressed and the fine tuning process entered, the CPU employs the two bits at positions 13 and 14 of the 16 bit per channel data and applies these to the internal 6 bit counter. This 6 bit counter controls 1/4th division and the 7.3 mV becomes divides by 4 to yield approximately 2 mV per step as the DAC-2 output. Following the 1 step variation, the LED lights, DAC greater than VR status is checked, and counter decrement is performed.

After repeating this operation 8 times, via the lowpass filter, two steps (−4 mV) down count is performed. These data are then written into memory IC205.

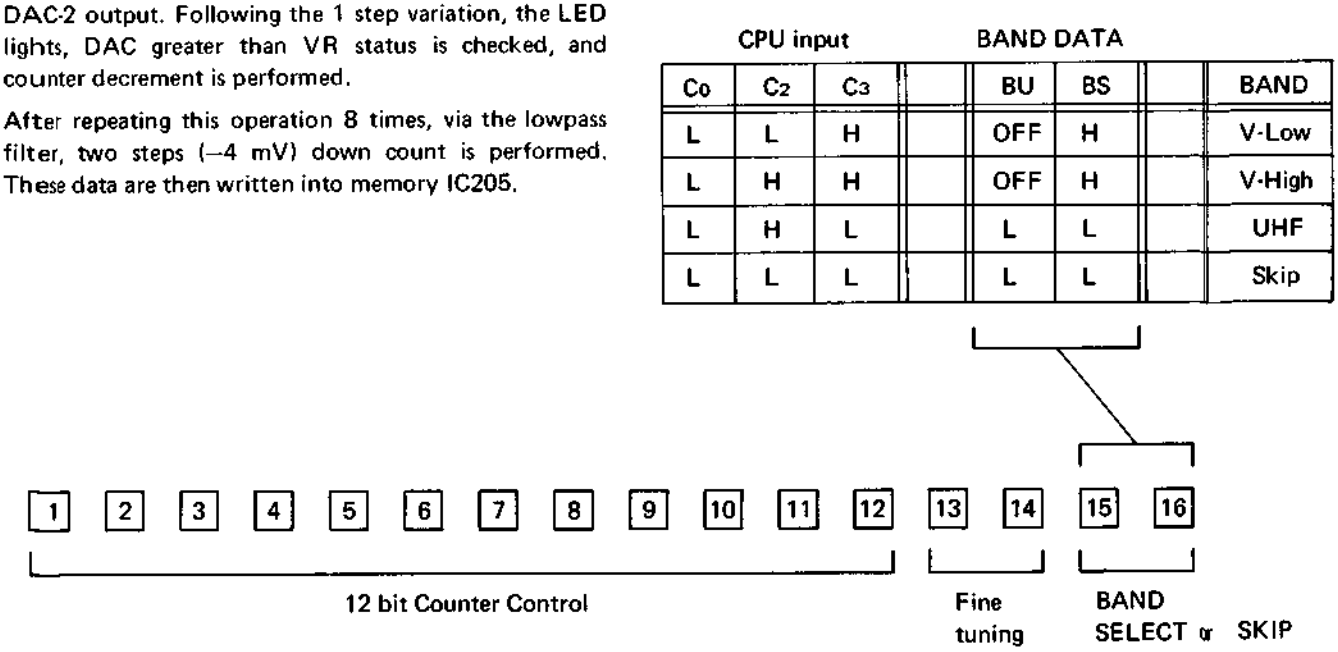

Fig. 3-42 16 bit CH data

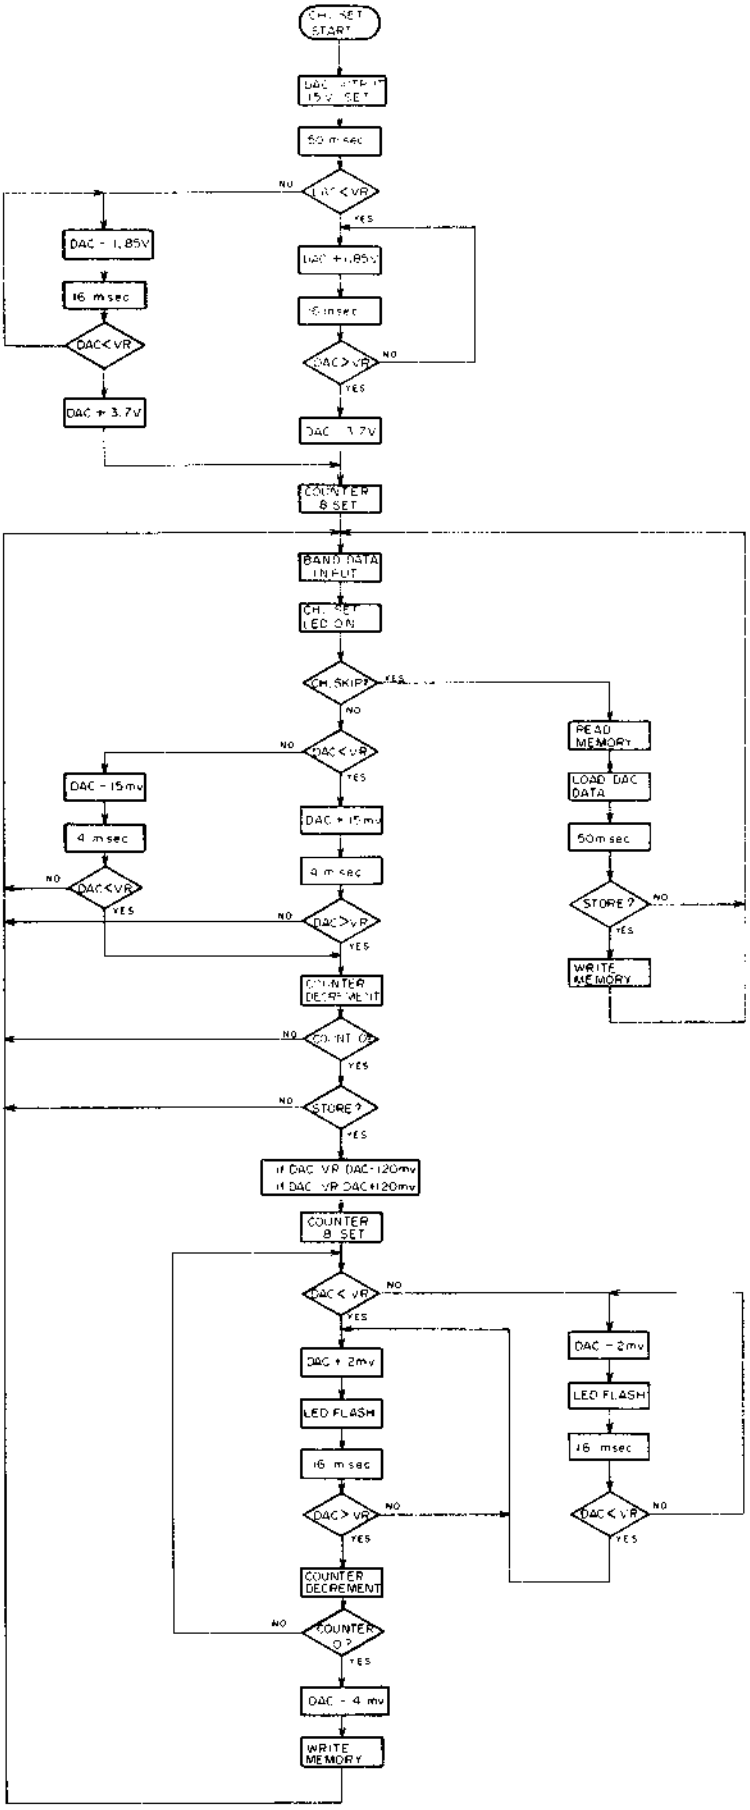

Fig. 3-43 Tuning system flow chart

2. Tuning operation outline

The microcomputer tuning system of this model is controlled by IC207 (μPD552C-088) of the T/T board. Refer to the block diagram. Basically, the tuner CPU controls the following functions.

1) Operation during tuning with PRESET control
2) Tuning operation using channel data written into memory IC
3) Write tuning data into memory
4) Channel skip

1) Tuning operation with PRESET control

With the channel PRESET switch set to ON, tuning becomes performed by the DC voltage value adjusted by the channel PRESET control. This VR adjusts the tuning voltage (BT) supplied to the tuner. Simultaneously, the DC voltage from the PRESET VR goes to the + side of the DC comparator, where it is compared with the input of the – side. The comparator output is supplied to CPU port C1.

This output is high level if the PRESET VR value is greater than the DAC output, and low level if it is less. Therefore, the CPU checks the PRESET VR DC voltage by polling the input level at port C1.

For example, if the PRESET VR value is greater than than the DAC value, high appears at CPU port C1 and the 4 bit data of port E control the IC202 (MN204E) DAC. The DAC contains an internal 12 bit counter and these data control the up/down counting direction.

Count is performed in steps from 1 to 4096. These DAC output steps are pulse width modulated and supplied to the lowpass filter. According to the pulse width, the LPF supplies a DC voltage to the – input of the DC comparator. The 12 bit counter control continues until the DC voltages of the PRESET VR and DAC output become essentially equal. Consequently, variation continues until the DAC voltage reaches the range of approximately ±0.4 mV of the PRESET VR voltage.

To summarize, when performing tuning adjustement, the PRESET switch is set to ON, then while observing the TV display, the PRESET VR is adjusted to the optimum setting. From this point, the CPU automatically instructs the DAC to produce an equal voltage to the PRESET VR setting potential, which becomes supplied as the LPF output.

In this state, when the STORE button is pressed, the DAC control data are automatically entered into the memory IC as the 16 bits per channel data.

2) Channel data memory

After tuning by use of the PRESET VR, pressing the STORE button writes the channel data into the memory IC. The memory storage capacity is 16 bits per channel times 16 channels, or 256 bits. About 2 to 3 seconds after the STORE button has been pressed, the CPU adjusts the tuning voltage to within approximately ±2 mV of the PRESET VR potential. During this time, the preset LED flashes on and off to indicate tuning operation.

When fine tuning is completed, the tuning data become written into the memory IC. Channel data write in commands from the CPU are in the form of 4 bit syllables. Thus, by sending 4 bit parallel data from the CPU 4 times, 16 bit data become written into the memory IC.

3) Write in timing

The timing diagram indicates the tuning data write in operation. At point (1) of the diagram, the memory lower group (G0) is set to input mode. Data input is performed at the pulse fall component of terminal CE. At the start of the CE fall component, the command (0, 0, 0, 0) is issued for setting the lower group to input mode, then the channel address data are entered. These data specify the channel from among the 12 memory channels. Addressing is performed using 4 bit BCD code.

Channel address data are entered at the start of the CE rise component (2). After setting the channel address (1 to 12), the data corresponding the particular channel are entered into the 16 bit memory. At the CE fall component, data write in command is sent to the G0 (group 0) area of the memory. Afterwards, at the rise component of CE, these are written into Data-1 (G0). In sequence, Data-2 (G1) input mode is set, and Data-3 (G2) and Data-4 (G3) are written. Maximum time required for write in is about 200 msec. Refer to the drawing for 16 bit data write in and data content.

4) Tuning data readout

Preset stations become tuned automatically when the CHANNEL button is pressed. Tuning is performed by using the 16 bit data sored in the memory and the specified channel is selected. These data are non-volatile and do not become erased when the power is cut off.

When the CHANNEL button is pressed, the CPU transfers the memory data at the following timing.

The CPU sets the command input mode for the lower address (G0) of the 16 bit memory. This is performed at the initial fall of CE by entering 0000 data drom the CPU into the memory.

Channel address data are entered at the CE rise component. The CPU detects which CHANNEL button has been pressed and converts this information into 4 bit BCD code, which goes to the memory as the channel address data.

At the next CE fall, the memory data output mode becomes set. Consequently, data in 4 bit syllables are obtained from memory IC output terminals Data-1, Data-2, Data-3 and Data-4, comprising a total of 16 bits, which are supplied to CPU D ports. Via the CPU, these data are transferred to the DAC to yield a pulse width proportional to the precise tuning voltage. The DC tuning voltage is then supplied through the LPF to the tuner.

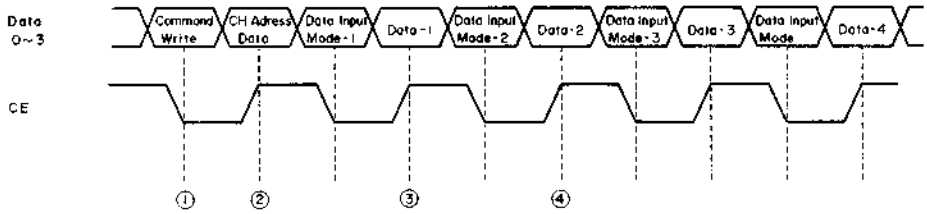

Fig. 3-44 Write in timing chart

3. IC Descriptions

1) MN1218A 256 bit MNOS non-volatile memory

This is an updated version of the MN1208A used for the HR-7700. The MN1218A is employed as the memory IC for the T/T circuit.

The MN1218A is a 256 bit non-volatile semiconductor memory which can be electrically reprogrammed. Memory capacity is 16 bits per TV channel, while internal data processing is possible in 4 bit groups (groups G0 to G3). Command inputs and data in/out processing are in 4 bit parallel format, allowing easy control by a microcomputer. The following table indicates data control of the MN1218A.

Control Operation	DA3	DA2	DA1	DA0
Set input mode for lower position address (G0)	L	L	L	L
Wire in	H	L	H	L
Set data input mode	H	L	H	H
Set data output mode	H	H	L	H
Input mode increment	H	H	L	L
Output mode increment	H	H	H	L

Table 3-6 MN1218A control code

In addition to the main 256 bit memory (channel data memory area), a 16 bit last channel memory area is included. This functions to store the channel data for the station selected prior to power on/off.

2) MN1204E guad D/A converter NMOS LSI

The MN1204 is a large scale integrated (LSI) circuit that incorporates a total of four circuits with capacities of 12 bits, 6 bits, 4 bits and 4 bits respectively. In the HR-7600, the 12 bit circuit is employed for obtaining the tuning voltage. The internal counter is controlled by the CPU 4 bit parallel data input (DA0 to DA3). Tuning voltage is produced by 12 bit counter operation to tield a pulse width corresponding to the selected channel.

Consequently, the DAC resolution becomes:

$2^{12} = 4096$ steps

These 4096 steps vary the pulse width during tuning to vary the tuning voltage from 0 to 30 V DC.

$\frac{30\ V}{4096} = 7.3$ mV/step

During the fine tuning process, this 7.3 mV per step is divided (2 bits) by 4, yielding approximately 2 mV per step.

FUNCTIONS

Data Input	4 bit parallel
Output	Pulse width modulated 12 bit counter output
Analog Voltage Resolution	4096 (12 bit control)
Output Pulse Period	3.15 msec
Oscillator Frequency	1.3 MHz

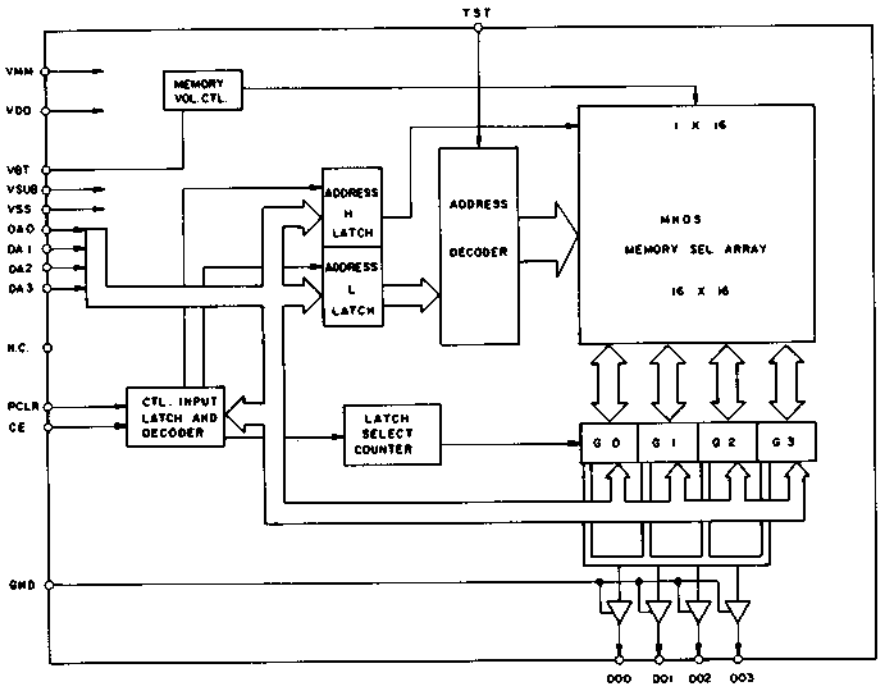

Fig. 3-46 MN1218A block diagram

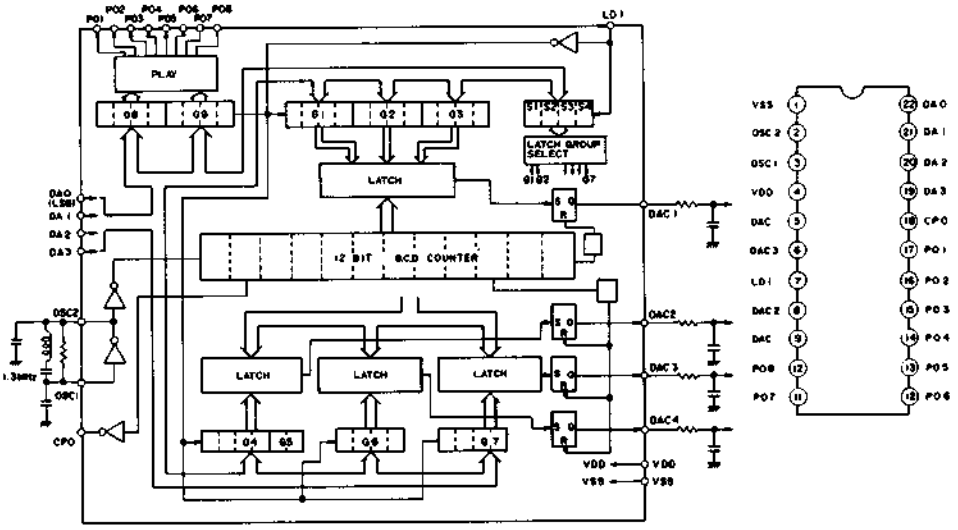

Fig. 3-47 MN1204E block diagram

3.6.3 Circuit description - 2

1. Reading of key input (Refer to Fig. 3-48.)
   The key input is read by IC206. The key scan data is emitted from pins 9–11 and 13–15 of IC206. The key input data is entered into port K of IC206. The dimmer key is not shown in the figure, since its input data is entered into the display drive IC401.
2. Display data and channel data outputs
   The display data is emitted to port A of IC401 via an inverter from pins 17–20 of IC206.
   Likewise, the channel data is emitted to a port of IC207 via an inverter from pins 17–20 of IC206.
   These data are discriminated by ENABLE signals. Pin 28 of IC206 is assigned as an output pin to DISPLAY DATA ENABLE and pins 22 and 23 of IC206 are assigned as output pins to CH DATA ENABLE.
3. TP202 test point
   When a short-circuit is made between TP202 and TP203 (GND) with an alligator clip or the like, the timer operates at 10 times the normal speed.
4. Channel LED drive
   The channel LEDs are driven by IC207. The channel data is read and processed by port A of IC207. This data is emitted to the cathode side of the LED via an inverter from port G of IC207 and then emitted to the anode side of the LED from port H of IC207.
5. Display drive
   The display is driven by IC401. The display data is fed to port A of IC401 from IC206. This data is then processed by an internal program, thus the filament display is driven by ports E, F, G and I.
6. AC detector
   When a power failure occurs, the timer CPU (MB8851AM-143L) is backed up by the discharging of C266 in the tuner/timer sub-board. However, since the operation of this CPU is assured at more than 3.5 V, the CPU is reset when the discharging voltage of C266 becomes 3.5 V. In addition, the lines to all other elements are cut off to extend the backup time as much as possible.
7. 1/16 count down
   The count pulse (reel FG pulse) is supplied via connector 31 from the mechanism control board. This pulse is waveform-shaped by IC203 and entered to pin 51 of IC211. In IC211, this waveform-shaped pulse is subjected to 1/16 count down and supplied to the CPU (MB8851AM-143L).

3.6.4 Input/output data to each CPU

The input/output data to each CPU is tabulated for reference.

3.6.5 Overall operation check

Timer control section

Item check	Procedure	Operation check
(1) Power failure indication	• Set MAINS POWER switch ON (after OFF for over 2 hours).	• 0.5 sec. later, "SUN 0:00" blinks. • CH No. indicator goes out.
(2) MAINS POWER switch ON	• Set sub-power switch ON.	• Sub-power indicator lights. CH No. indicator lights. • "SUN 0:00oooo" blinks.
(3) Clock setting	• Press CLOCK SET button.	• "SUN 0:00oo" appears. Second counting starts. Second indicator blinks.
(4) Second setting	• Press SET button.	• Blinking stops. Second is reset (29 or less is rounded to "0" second and 30 or more is to rounded to next minutes. • While pressing button, time-keeping is not performed.
(5) Minute setting	• Press SELECT button. • Press SET button.	• Minute indicator blinks. • Blinking stops. • Whenever button is pressed, minute advances. When continue pressing for more than 1 second, minute changing is speeded up at rate of 6 digits/sec. • Minute is not carried over to hr. (00 → 59 → 00)
(6) Hour setting	• Press SELECT button. • Press SET button.	• Hour indicator blinks. • Blinking stops. • Whenever button is pressed, hour advances. When continue pressing for more than 1 second, hour changing is speeded up at rate of 6 digits/sec. • Hour is not carried over to day.
(7) Day setting	• Press SELECT button. • Press SET button.	• Day indicator blinks. • Blinking stops. • Whenever button is pressed, day changes. When continue pressing for more than 1 second, day changing is speeded up. (SUN → SAT → SUN)
(8) Second setting	• Press SELECT button.	• Return to item (3).
(9) Automatic return to clock setting	• Leave timer alone with clock having been set.	• 1 to 2 minutes later, display returns to Clock mode. • Display changes from seconds to time-keeping.
(10) Program setting	• Press PROGRAM SET button.	• Display changes to program. Program No. : 1 appears. CH No. : 1 (blinking) Day : 1st SUN Time : 0:00 Recording length: ooo
(11) Channel setting for recording	• Press SET button.	• Blinking stops. • Whenever button is pressed, Channel Number changes. • When continue pressing for more than 1 second, CH No. changing is speeded up at rate of about 4 digits/sec. • Skipping is not possible. (1 → 12 → 1)

3-60

Item check	Procedure	Operation check
(12) Day setting for recording to start	• Press SELECT button. • Press SET button.	• 1st SUN blinks. • Blinking stops. • Whenever button is pressed, day changes. • When continue pressing for more than 1 second, day changing is speeded up. (1st SUN → 1st SAT → 2nd SUN → 2nd SAT → 1st SUN . . . 2nd SAT → 1st SUN)
(13) Record (switch on) time (hour digits)	• Press SELECT button. • Press SET button.	• Same as item (6). • Same as item (6).
(14) Record (switch on) time (minute digits)	• Press SELECT button. • Press SET button.	• Same as item (5). • Same as item (5).
(15) Recording length	• Press SELECT button. • Press SET button.	• 3 digits for recording length blink. • Blinking stops. • Whenever button is pressed, length increases in 5-minute increments. • When continue pressing for more than 1 second, length indication changing is speeded up. (000 → 395 → 000)
(16) Channel to be recorded	• Press SELECT button.	• Set to channel to be recorded and return to (11).
(17) Repeat setting	• Press REPEAT button.	• Repeat indication appears. • The corresponding program is repeated per entered data.
(18) Program Number setting	• Press PROGRAM No. button.	• Whenever button is pressed, Program No. changes. (1 → 8 → 1)
(19) Cancellation of entered data	• Press CANCEL button.	• Contents of displayed program is cancelled. Return to item (10). (However, Program No. does not change.)
(20) Automatic cancelling of entered data	• Press PROGRAM No. button and CANCEL button is simultaneously.	• Contents of programs 1–8 are all cancelled. Return to item (10).
(21) Automatic return to clock setting	• Leave timer alone with program having been set.	• 1 to 2 minutes later, timer returns to Clock mode.
(22) Program data becomes void.		• When recording length is not set, the corresponding program setting becomes void.
(23) Program priority		• Among the programs preset for same time, the one with smaller Program No. is given priority. • When preset program times overlap the earlier-started program will be interrupted by the latter one.
(24) Timer operation	• Set Sub-power switch to TIMER. • 10 seconds before specified time.	• Timer indicator lights. • Power ON indicator goes out. • CH No. indicator goes out. • Counter display disappears. • Power ON indicator lights. • Counter display turns ON. • Specified CH No. indicator lights. • In recording mode, machine enters into loading pause mode. (Pre-start output is emitted.)

Item check	Procedure	Operation check
(24) Timer operation (continued)	• Specified time is reached.	• Pause is released. Recording starts. (Recording-start output is emitted.)
(25) Program check during recording	• Press PROGRAM SET button. • In case of program being recorded (Press SELECT button.) • In case of program other than the one being recorded.	• Clock changes to program display. • For a program being recorded, only the length can be corrected. 1. Recording length > elapsed time → recording is continued. 2. Recording length ≦ elapsed time → recording is cancelled within 2 minutes. • Same as in normal PROGRAM SET condition.
(26) Completion of recording	• Recording-start time plus recording length	• Pre-start output and recording-start output turn OFF simultaneously. • When not in Repeat mode, program data are cancelled within 1 minute.
(27) Continued program recording		• Program recording continues when preset times overlap. Pre-start operation is not performed.
(28) Timer sleep operation	• Set Sub-power switch to TIMER during recording. • Press SELECT button.	• "SLEEP" lights on counter display. • Recording length indicator shows 60 minutes. • Only recording length can be changed. • 60 → 395 → 0 → 395 • Same as in normal PROGRAM SET condition.
(29) Program setting with Sub-power switch OFF	• Press PROGRAM SET button.	• Same as in normal PROGRAM SET condition.
(30) Channel selection during recording		• Channel is locked during recording. • Channel selection can be made in Pause mode.
(31) Carry-over data		• In the Clock mode, each digit should be carried over to the next. (Example) SAT 23-hr 59-min → SUN 0-hr 00-min

Tuner control section

Item check	Procedure	Operation check
(1) Channel setting	• Set CH (PRESET) switch to ON. • Set Band switch correctly. • Turn the tuning control knob.	• About 1 second later, (CH SET) indicator lights. • AFC is defeated. • Band changes according to setting of band switch. • Tuning voltage (BT) changes according to the turning of the tuning control knob.
(2) Store	• Push STORE knob.	• After (CH SET) indicator blinks for about 2 seconds, preset channel is stored in memory.
(3) Skip setting	• Set the PRESET switch to SKIP. • Push STORE knob.	• Displayed channel will be skipped. However, CH No. 1 cannot be skipped.
(4) Skip cancel	• Perform channel setting procedures again.	• Skip is cancelled.
(5) Last channel memory	• Select a channel. • Sub-power switch OFF → ON	• Selected channel Number indicator lights. • After power ON, same channel Number indicator lights.
(6) Sound mute	• Change channels.	• Sound mute should function.
(7) AFC defeat	• Change channels.	• AFC turns OFF (defeated).
(8) AFC ON/OFF	• Set AFC switch ON. • Set AFC switch OFF.	• AFC turns ON. • AFC turns OFF (defeated).
(9) Channel memory	• Turn MAINS POWER switch OFF and ON.	• Stored data should not change.

Tape counter section

Item check	Procedure	Operation check
(1) Counting operation	• Count the number of pulses input.	• Displayed figure is 1/16 of number of count pulses.
(2) UP/DOWN counting	• Run the tape in the forward direction. • Rewind the tape.	• Count-up is performed. • Count-down is performed.
(3) Reset	• Press COUNTER RESET button.	• Counter is reset to zero. • Valid only when counter is displayed.
(4) Counter output	• Set counter to zero. • ±100 count UP : 9900–9999 DOWN : 0099–0	• Zero output is emitted. (0 = L) • Count output is emitted. (0 ± 100 or less = L)
(5) Counter accuracy	• In count UP/DOWN, input of same number of pulses	• ±1 count or less

Remote control operation

Check item	Procedure	Operation check
(1) Channel changing	• Press the TV PROG. button.	• Channels change upward. • When continue pressing, channels change upward at rate of about 0.5 Hz/sec.

Display section

Check item	Procedure	Operation check
(1) Dimmer operation	• Press DIMMER button. (Make visual check.) • Press DIMMER button again.	• Brightness lowers. • Brightness should be consistant for all display information. • Brightness becomes normal level as before.
(2) Irregular brightness	• Make a visual check.	• Brightness should be consistant for all display information.
(3) Button operation		• Each button should function by applying moderate pressure.
(4) Pressing various buttons at the same time	• Press combinations of buttons not prescribed for simultaneous operation.	• Abnormal operation should not occur.

SECTION 4
MECHANICAL ADJUSTMENT

4.1 GENERAL

4.1.1 Precautions

IMPORTANT:

1. Disconnect from power before removing or soldering components.
2. When removing a screw from the chassis, be careful not to drop it into the mechanism. If a screw should be dropped, be sure to retrieve it.
3. Be extremely careful not to damage either the upper or lower head drum assemblies.
4. The tape transport mechanism has been precisely adjusted at the factory and ordinarily does not require readjustment.
5. When removing a part, be very careful not to damage or displace other parts. (Be especially careful with the guide poles and rotary video head drum.)
6. The cassette switch is mounted to the cassette housing. Therefore, the set cannot be operated without the cassette housing (i.e., while cap housing of the cassette housing is disengaged). Therefore, to operate the set without the cassette housing, set the cassette switch short jig (part no. PUJ43068) so as to press the cap housing inward. Also disable the photo transistor sensors by applying opaque covers. After completing checks and repairs, be sure to remove the covers.
7. When raising the set on its side, it is better for stability not to remove the front panel.
8. Tighten the screws carefully to avoid damage to the cabinet.

4.1.2 Required jigs and tools

For proper mechanical adjustment, the following jigs and tools are strongly recommended. Without them, a long trial-and error period would be necessary.

In addition, general-purpose tools and a metric hex key (not supplied by JVC) are required.
The hex key needed for this model is 1.5 mm size.

JVC Alignment tape MH-2 	Master plane jig PUJ42146 	Height gauge PUJ42147-2 	JVC oil PU41761 Torque gauge ass'y PUJ48075-2 (Torque meter 600ATG, Torque gauge head PUJ48016-2) 	Back tension cassette gauge PUJ48076 	Cassette switch short jig PUJ43068 	Audio/Control head position tool PUJ47351-2 

Table 4-1 Jigs and tools

NOTE: See section 5.1 required test equipment and jigs regarding electrical adjustment.

4.1.3 Disassembly

A: External covers

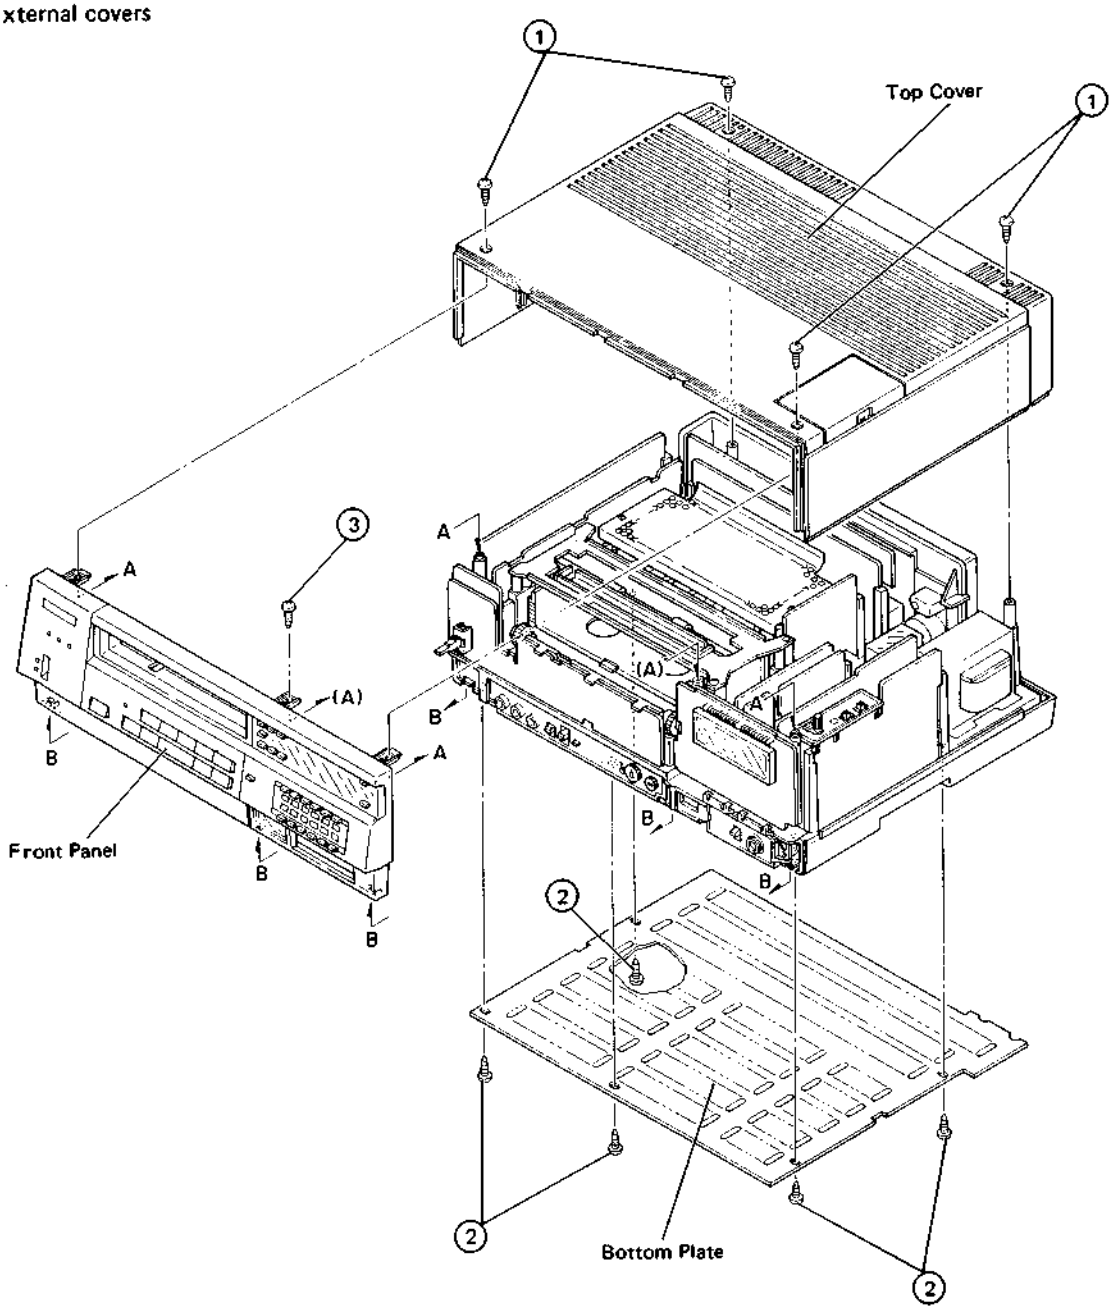

Fig. 4-1(a) External covers

1. Take out four screws (1) and remove the top cover.
2. Take out five screws (2) and remove the bottom plate.
3. To remove the front panel, take out one screw (3). As shown in Fig. 4-1 (a), the front panel is held by plastic post structures at two points A and three points B. Slightly raise the front panel to disengage points A, pull the panel outward by a small amount, then apply downward pressure to disengage points B. Afterwards, pull the panel gently outwards to remove.
4. To reassemble, reverse the above steps. Observe that points A and B are properly re-engaged.

B: Circuit board assemblies

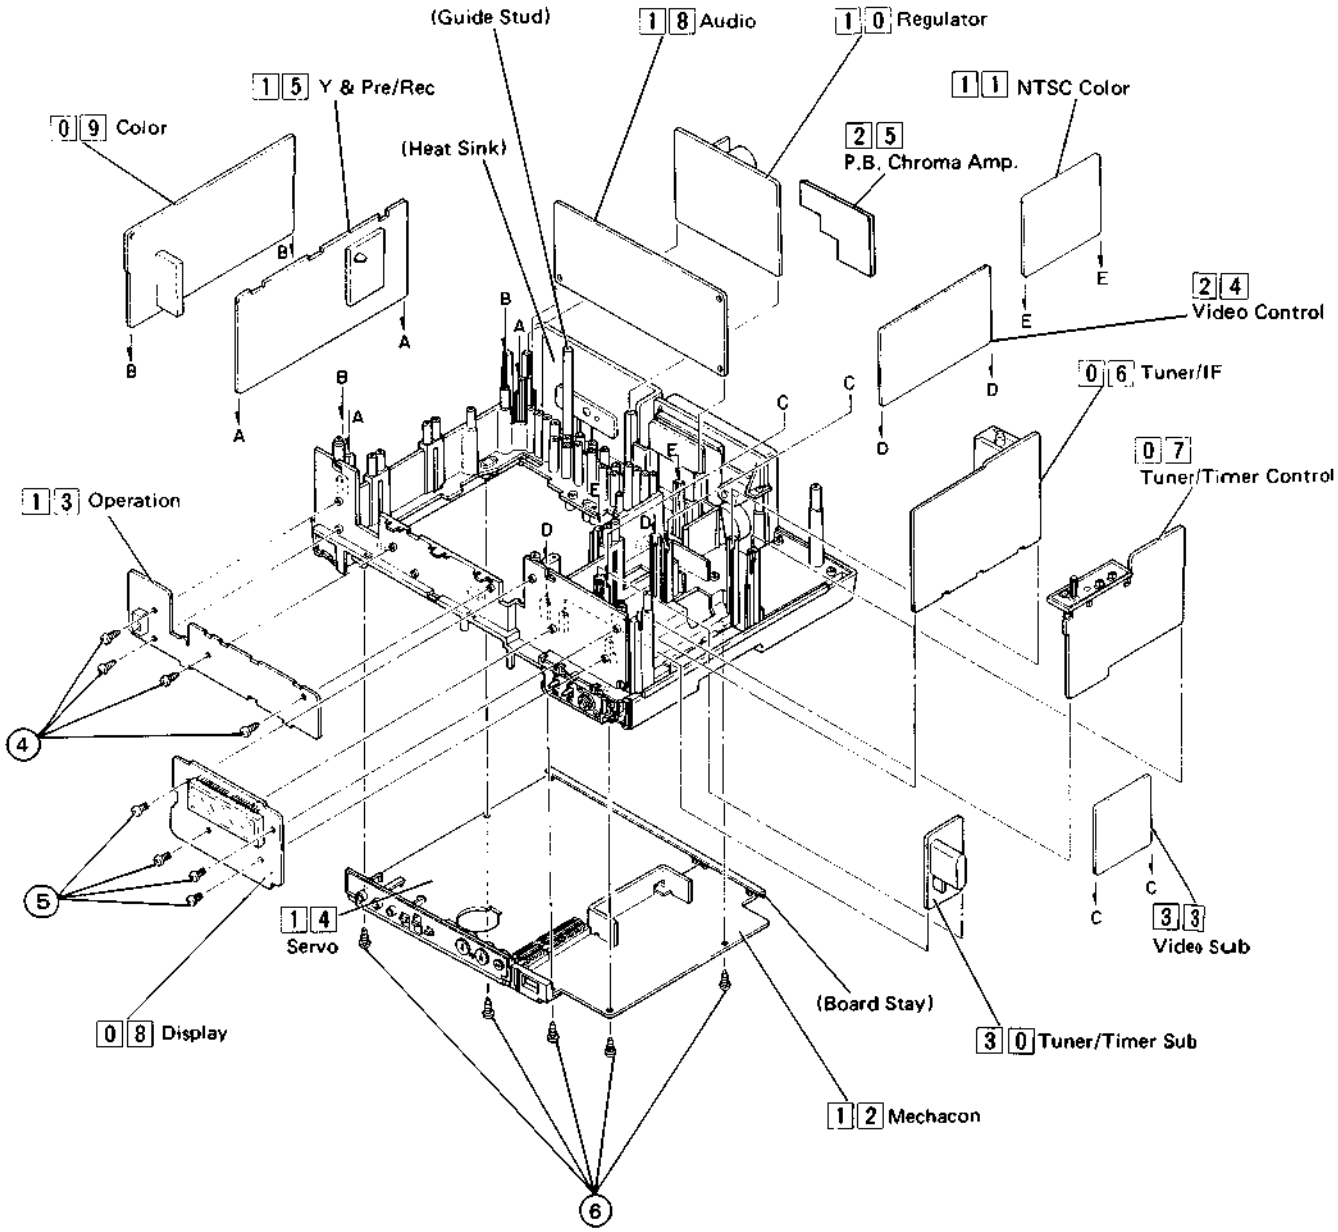

Fig. 4-1(b) Circuit boards

1. Operation board assembly
   Take out four screws ④ and remove the operation board assembly.
2. Display board assembly
   Take out four screws ⑤ and remove the display board assembly.
3. Servo and Mechacom board assemblies
   Take out five screws ⑥ and remove the board stay from the chassis assembly.
4. P.B. Chroma Amp. board assembly
   Pull the P.B. chroma Amp board upward from the main deck assembly board guide.
5. Other board assemblies
   Remove the Clolr, Y & Pre/Rec, Regulator, Audio, Video Control, NTSC color, Tuner/IF, Tuner Timer Control, Video Sub and Tuner/Timer sub board assemblies by pulling them upward from the chassis assembly board guides.
6. Heat sink
   The heat sink, with power transistor and servo power transistor boards, can be removed by pulling it upward from the guide stud of the chassis assembly.

4.1.4 Layout of main mechanical parts

A: Top view and parts identification

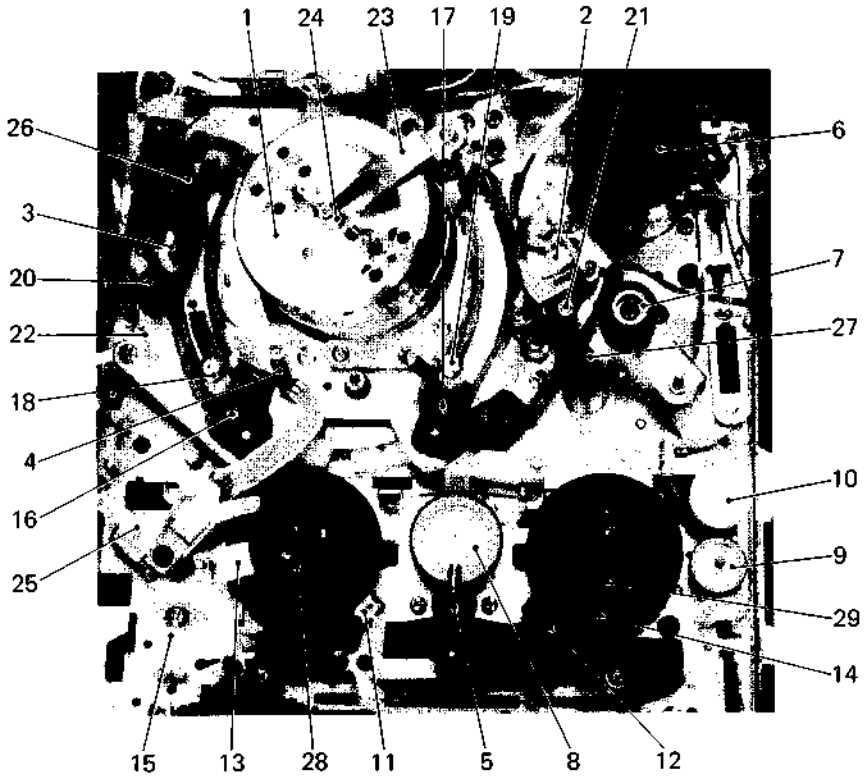

Fig. 4-2(a) Top view

Category	Symbol No.	Part Name	Part No.	Category	Symbol No.	Part Name	Part No.
A	1	Upper drum ass'y	PU31332L	E	16	Supply pole base ass'y	PU48740B
	2	Audio/Control head ass'y	PU51903		17	Take-up pole base ass'y	PU48745B

Table 4-2(b) Bottom view main parts list

4.2 PERIODIC MAINTENANCE

The following procedures are recommended for maintaining optimum performance and reliability of this video cassette recorder.

4.2.1 Cleaning

For cleaning, use a lint-free cloth or gauze dampened with alcohol.

A: Tape transport system

1. The following components should be cleaned after every 500 hours of use.
   1) Supply guide pin
   2) Cue head (Tension pole)
   3) Supply guide pole
   4) Full erase head
   5) Impedance roller
   6) Supply guide roller
   7) Supply slant pole (Supply pole base assembly)
   8) Video head and Drum system
   9) Commutator
   10) Brush
   11) Take-up slant pole (Take-up pole base assembly)
   12) Take-up guide roller
   13) Audio/Control head and Audio erase head
   14) Take-up guide pole
   15) Pinch roller
   16) Capstan
2. Since above parts come in direct contact with video tape, they tend to collect dust particles. If allowed to accumulate, dust may lead to damage to the video tape and above parts.
3. After cleaning with alcohol, allow the parts to dry thoroughly before using a cassette tape.

NOTE:
When cleaning the two video heads on the upper drum, do not clean them with a vertical stroke.
Use only a gentle back and forth motion in the direction of the tape path.
Use care since they are easily damaged.
When cleaning video heads, A/C head and erase heads, use a lint-free cloth dampened with alcohol.

B: Reel drive system

1. The following components should be cleaned after every 1,000 hours of use.

   – Upper section –
   17) Reel motor
   18) Reel idler
   19) Supply reel disk
   20) Supply main brake
   21) Take-up reel disk
   22) Take-up main brake
   23) Take-up clutch
   24) Take-up idler

   – Bottom section –
   25) Capstan motor
   26) Capstan belt
   27) Capstan flwheel
   28) Take-up clutch belt
   29) Take-up clutch
   30) Loading gear
   31) Loading belt
   32) Loading motor

   – Cassette housing section –
   33) Rollers of roller assembly
   34) Cassette belt
   35) Cassette motor
2. The above revolving parts are of rubber or come in direct contact with rubber parts.
   Rubber dust can accumulate and interfere with proper operation.
3. Avoid using excessive alcohol when cleaning rubber parts.

4.2.2 Lubrication

The following components should be lubricated with JVC oil after every 2,000 hours of use.

1) Shaft of the supply reel disk
2) Shaft of the take-up reel disk

After cleaning above shafts with alcohol, lubricate these shafts with one or two drops of JVC oil.
Do not over lubricate.

4.2.3 Service schedule for main components

The following chart lists the parts of the units which should receive periodic servicing at the recommended intervals.

Name	Periodic Service Schedule (operating hours)				
	1 000	2 000	3 000	4 000	5 000
Upper drum assembly	○	●	○	●	○
Brush assembly and commutator		●		●	
Cassette motor assembly			●		
Cassette belt		●		●	
Roller assembly (for cassette housing)		●		●	
Take-up clutch assembly		●		●	
Take-up clutch belt		●		●	
Take-up idler assembly		●		●	
Reel motor assembly		●		●	
Reel idler assembly		●		●	
Capstan motor assembly		●		●	
Capstan belt		●		●	
Loading motor			●		
Loading belt		●		●	
Audio/Control head assembly			●		
Tension band assembly		●		●	
Supply reel disk assembly			●		
Take-up reel disk assembly			●		
Loading tension brake pad		●		●	
Take-up back tension brake pad		●		●	
Pinch roller assembly			●		
Cue head					●
Full erase head					●

Table 4-3 Standard service periods

○ Check and replace if necessary.

● Replace.

NOTE:

Even if the unit is not used frequently, cleaning, lubrication and replacement of the belts should be undertaken every 2 years.

4.3 MAIN ASSEMBLY REPLACEMENTS

4.3.1 Cassette housing assembly, cassette motor assembly and cassette switch

A: Cassette housing assembly

1. Remove the top cover and front panel.
2. Take out four screws Ⓐ and disconnect the cap housing (see Fig. 4-3). Carefully lift the cassette housing upward to remove it. During reaasembly, use care that the record safety arm does not damage the leaf switch.

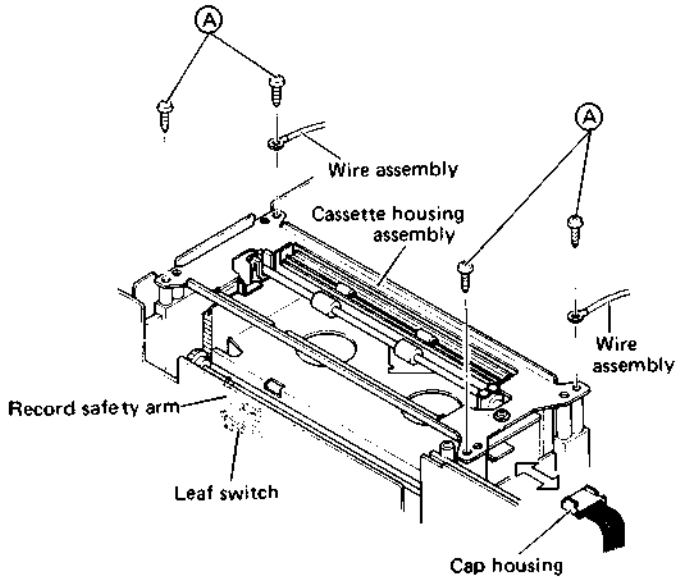

Fig. 4-3 Cassette housing removal

3. To reinstall the cassette housing, first connect the cap housing. Gently set the cassette housing into the main deck while using care that the record safety arm does not damage the leaf switch. Check that the housing is properly engaged at points A, B, C and D as indicated in Fig. 4-4.

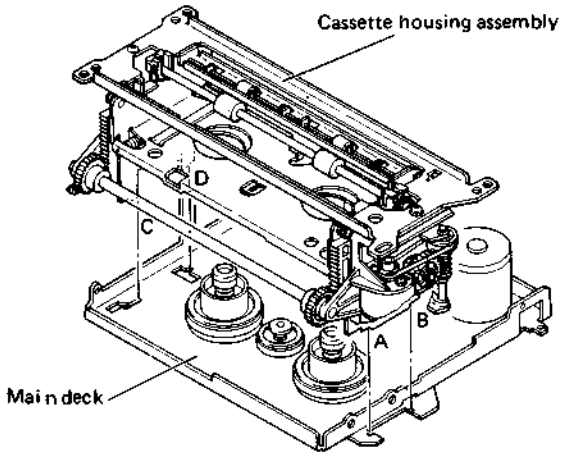

Fig. 4-4 Cassette housing setting

4. Insert the four screws Ⓐ , shown in Fig. 4-3 (also reattach the two wire assemblies), but do not tighten the screws.
5. Shift the cassette housing so that points C and D (Fig. 4-4) are at their most rearward (toward the drum assembly) positions, then tighten the four screws Ⓐ.
6. Use a cassette tape and check for smooth operation of the cassette housing assembly. Also confirm operation of the record safety arm.

NOTE: The cassette switch is mounted on the cassette housing. For this reason, the set becomes inoperative when the cassette housing is removed (cap housing disconnected).

B: Cassette motor assembly

1. Unsolder the cassette motor wires.

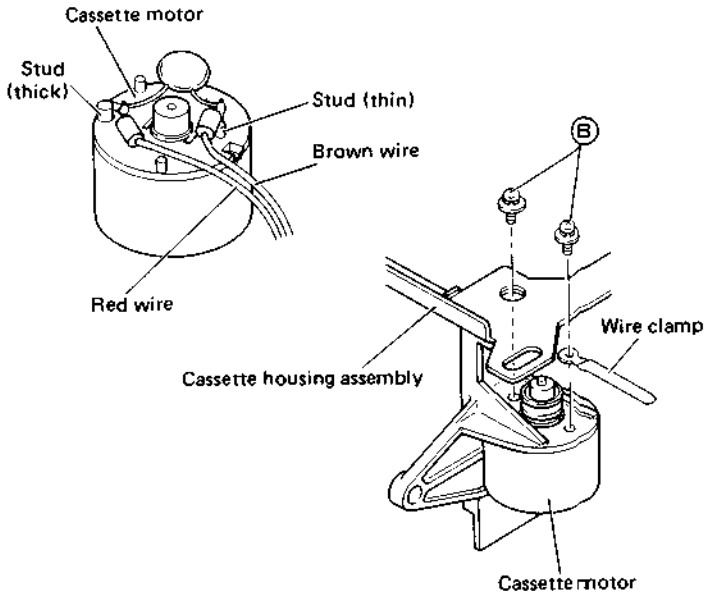

Fig. 4-5 Cassette motor replacement

2. Disengage the belt from the motor pulley, take out two screws Ⓑ and remove the cassette motor. See Fig. 4-5.
3. Reinstall the cassette motor with the two screws Ⓑ, together with the wire clamp, then reengage the belt.
4. Solder the wire coming from connector 1 of the cap housing to the cassette motor terminal adjacent to the thicker diameter stud. This is the minus (−) terminal. Observe that wires do not contact rotating parts.
5. Use a cassette tape and check for smooth operation of the cassette housing assembly. Confirm operation of the record safety arm.

C: Cassette switch

1. Unsolder the cassette switch wires.

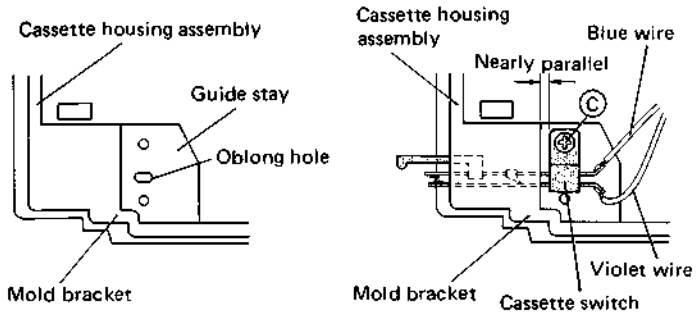

Fig. 4-6 Cassette switch replacement

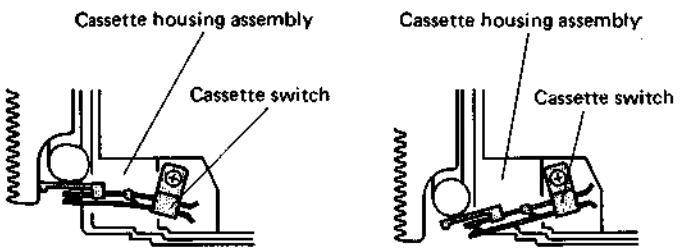
2. Take out one screw Ⓒ and remove the cassette switch toward the right. See Fig. 4-6.
3. When reinstalling the cassette switch, use care not to damage the contacts. Insert the cassette switch toward the left and engage the stud at the rear of the switch with the oblong hole of the guide stay. Position the switch so that is nearly parallel with the mold bracket, as shown in Fig. 4-6, then secure with screw Ⓒ.
4. Resolder the cassette switch wires.

NOTE:
When the cassette switch closes, short brake is applied to the cassette motor, stopping rotation. Consequently, the mounting position of the switch determines the cassette setting position. After the cassette housing has been installed at the correct position, perform the following checks and readjust the cassette switch position as required.

1) Supply power and insert a cassette. Observe the cassette lowering and setting operation. Check for the following symptoms.
2) Cassette position too high
   In this case, the switch contacts are too high, as indicated in Fig. 4-7 (a). The switch closes (on state) before the cassette has been fully lowered. Test by gently pressing the cassette by hand to determine whether it can be lowered further.
3) Eject mode entered
   After the cassette motor rotates, if the cassette switch does not close within about 7 seconds, the eject mode is automatically entered. This effect can be caused if the switch contacts are positioned too low, as shown in Fig. 4-7 (b). At this time, even though the cassette is fully lowered, the cassette switch contacts do not close.
4) Rebound effect
   After reaching the bottom of travel, the cassette rebounds slightly upward. In this case, there is a slight delay between maximum lowering and cassette switch closing. Residual tension of the cassette belt then pulls the cassette slightly upward.
5) If any of the above effects is observed, adjust the cassette switch position to obtain precise timing between the end of cassette travel and cassette switch closing.
6) Use a cassette tape and check for smooth operation of the cassette housing assembly. Confirm functioning of the record safety arm.



(a) Too high (b) Too low

Fig. 4-7 Cassette switch adjustment

4.3.2 Upper drum, brush assembly and commutator

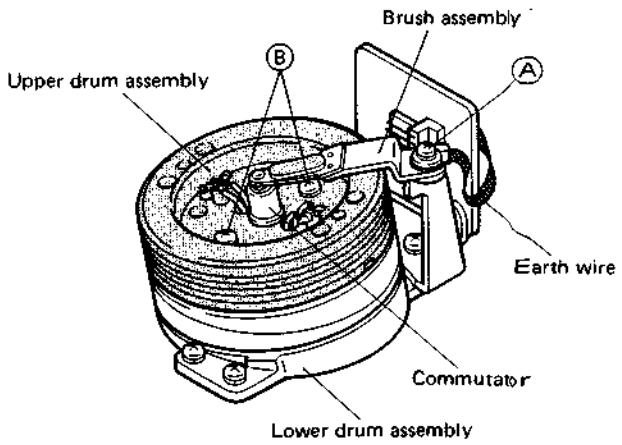


Fig. 4-8 Upper drum replacement

1. Take out screw Ⓐ , disconnect the earth wire and remove the brush assembly. See Fig. 4-8.
2. Remove the commutator from the drum motor shaft.

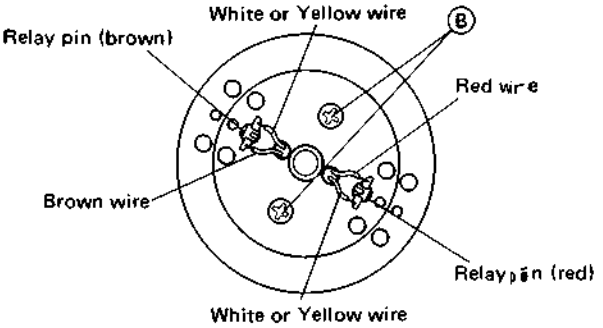

Fig. 4-9 Upper drum wiring

3. Unsolder the four wires connecting the lower drum assembly from the relay pins of upper drum assembly (perform quickly to avoid damaging the wires) as shown in Fig. 4-9.
4. Take out two screws Ⓑ and remove the upper drum assembly in the upward direction.
5. Use alcohol to clean the lower face of the new upper drum assembly and the upper face of the lower drum assembly. When handling and installing the new upper drum, avoid directly touching the video heads and use care not to scratch the drum.
6. Reassemble by reversing the above steps. When resoldering, observe the correct channels (brown: CH-1, red: CH-2) and avoid overheating the wires. Use screw Ⓐ to secure the brush assembly together with the earth wire to the video head board. Check that the brush assembly is positioned at the center of the commutator.
7. Perform the following checks and adjustments
   1) Video head switching position (see section 5.4.7).
   2) Tracking preset (see section 5.4.8).
   3) Overall checks and adjustment of the signal systems (see section 5.5).
   4) FM noise pulse width (see section 5.4.13).
   5) Control head phase (see section 4.5.8).

4.3.3 Take-up clutch and take-up idler assemblies

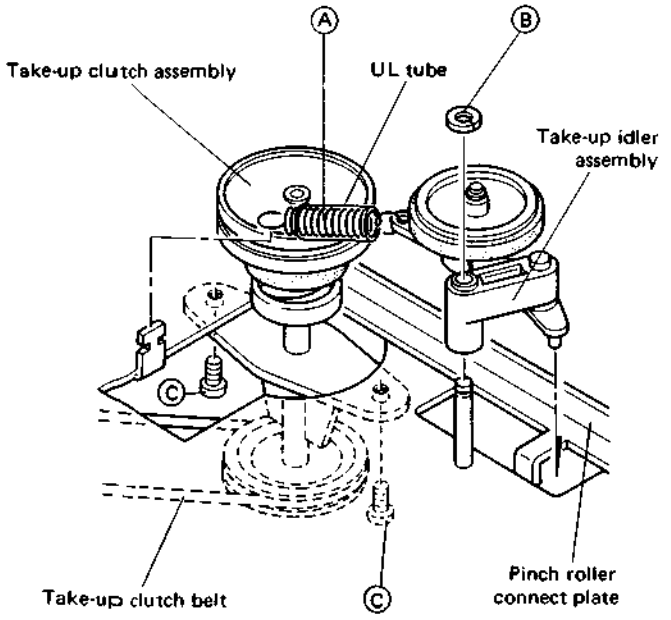

Fig. 4-10 Take-up clutch and take-up idler replacement

1. After unhooking the spring Ⓐ of the take-up idler from the deck, take off the slit washer Ⓑ to remove the take-up idler assembly in the upward direction and replace the take-up idler assembly.
2. From the bottom side, disengage the take-up clutch belt from the pulley of the take-up clutch assembly.
3. Take out two screws Ⓒ and replace the take-up clutch assembly.
4. Reassemble by reversing the above steps. At this time, clean the take-up clutch belt, take-up clutch and take-up idler.
5. Perform take-up torque check as follows.
6. Set for the Play mode without tape (refer to section 4.1.1-6).
7. Set the torque gauge on the take-up reel disk.

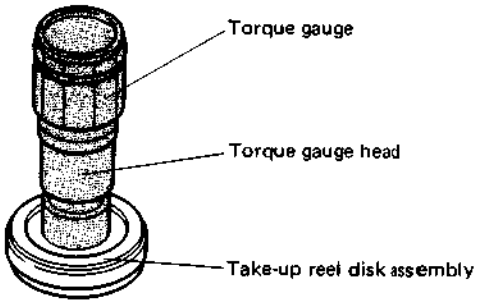

Fig. 4-11 Take up torque check

8. Relax the grip on the torque gauge so that the indicator needle and scale rotate at equal speeds, then read the indication. The correct value is between 60 and 100 gcm.
9. If not the correct value, confirm the conditions of the take-up idler spring and take-up clutch belt.

4.3.4 Reel motor and reel idler assemblies

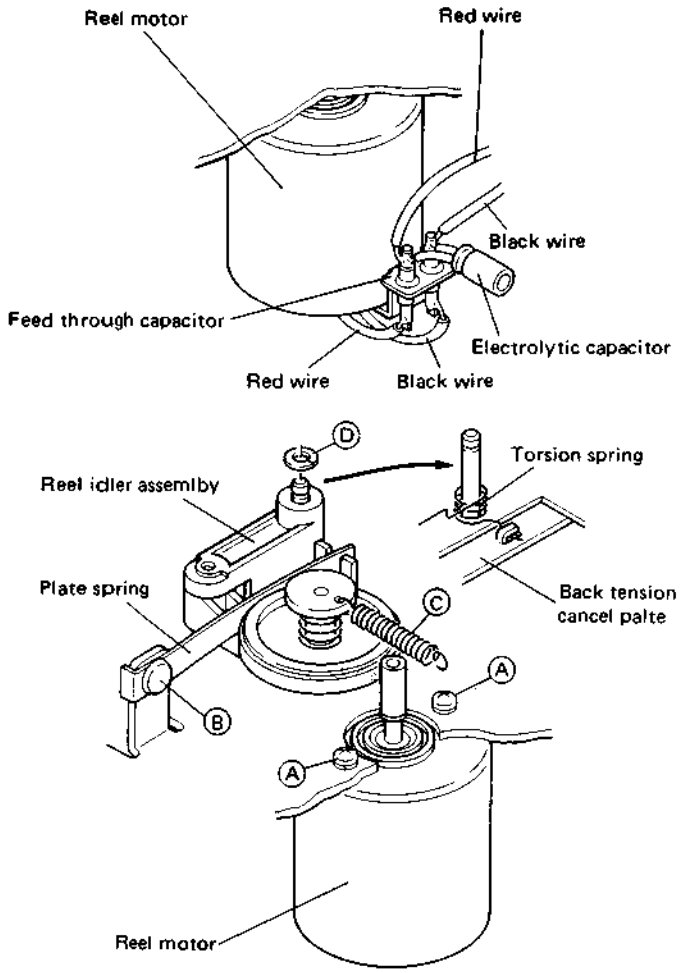

Fig. 4-12 Reel motor and reel idler replacement

1. Unsolder the wires from the feed through capacitor of the reel motor assembly from the bottom side as shown in Fig. 4-12.
2. Take out two screws (A) from the top side and replace the reel motor assembly from the bottom side.
3. After removing the reel motor assembly, take out the plastic rivet (B) and remove the plate spring.
4. After unhooking the spring (C) of the reel idler assembly, take off the slit washer (D) and replace the reel idler assembly.
   Use care regarding the washer and torsion spring when removing the reel idler assembly in the upward direction.
5. Reassemble by reversing the above steps.

4.3.5 Capstan motor assembly

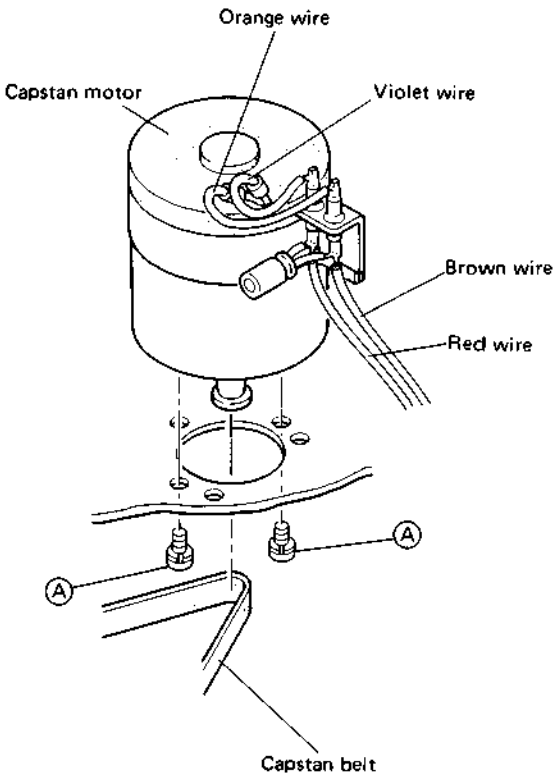

Fig. 4-13 Capstan motor replacement

1. Unsolder the wires from the feed through capacitor as shown in Fig. 4-13.
2. From the bottom side, disengage the capstan belt from the capstan motor pulley.
3. Take out two screws (A) and replace the capstan motor assembly.
4. Reassembly by reversing the above steps.
5. Perform the capstan discri. center check and adjustment (see section 5.4.5).

4.3.6 Loading motor assembly

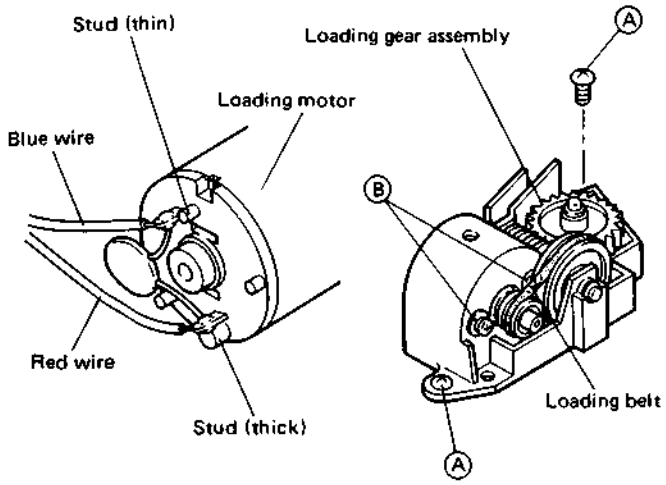

Fig. 4-14 Loading motor replacement

1. Take out two screws (A) and remove the loading gear assembly.
2. Unsolder the motor wires as shown in Fig. 4-14.
3. Disengage the loading belt from the motor pulley; take out two screws (B) and replace the loading motor.
4. Reassembly by reversing the above steps. Turn the loading rings by hand to end of travel (loading end position) and install the loading gear assembly.
5. Turn the loading motor pulley by hand to move the loading ring slightly in the unloading direction. Check for equal spacing between the supply pole guide and supply pole base, and between the take-up pole guide and take-up pole base. If not equal, the loading gear ass'y mounting position is incorrect. Repeat the above step 4.
6. The minus (–) terminal of the loading motor is adjacent to the thicker diameter stud. Solder the wire coming from connector 92 of the junction board to this terminal. Observe that wires do not contact rotating parts.

4.3.7 Audio/Control head assembly

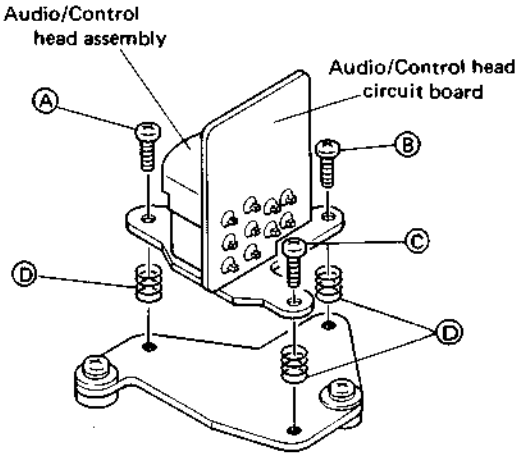

Fig. 4-15 A/C head replacement

1. Take out three screws (A), (B) and (C) to remove the A/C head assembly. Use care regarding the coil springs (D) as shown in Fig. 4-15.
2. Unsolder the ten terminals coming from A/C head assembly and remove the A/C head circuit board as shown in Fig. 4-15.
3. Replace the A/C head assembly and reassemble by reversing the above steps.
4. Perform the following checks and adjustments.

A: Tape transport adjustment

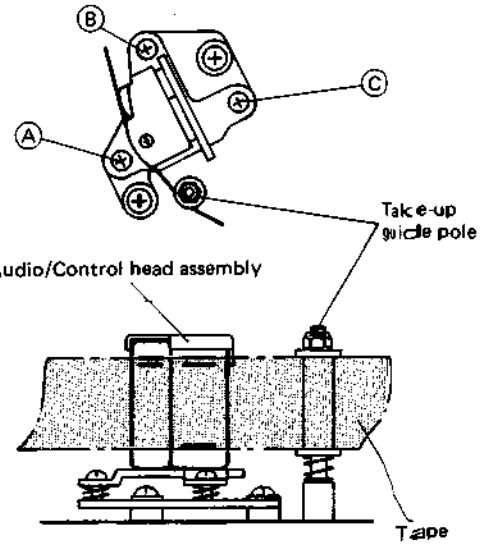

Fig. 4-16 A/C head adjustment

1. Employ a cassette tape and set for Play mode.
2. Turn screw (C) (Fig. 4-16) and adjust for smooth transport at the take-up guide pole. Do not adjust the height of the take-up guide pole itself.

B: Audio/Control head height and azimuth

- Incorrect audio/control head height can impair audio signal-to-noise ratio when playing back a pre-recorded tape.

1. Play alignment tape (6 kHz and stairstep signals) and measure the audio output level.
2. Turn screws Ⓐ, Ⓑ and Ⓒ in succession by small and equal increments at a time and adjust for amximum audio output level. With reference to screw Ⓐ , adjust azimuth with screw Ⓑ and screw Ⓒ so that small tape wrinkles are not produced at the guide pole, but at the same time, audio output becomes maximum and level fluctuations minimum.
   It is suggested to first turn screw Ⓐ by a small amount, then turn screws Ⓑ and Ⓒ by an equal amount and set for maximum output.

C: Final checks and adjustments

1. Perform the interchangeability adjustment (see section 4.5).
2. Perform the audio system adjustment (see section 5.6).

4.3.8 Reel disk, tension band and cue head

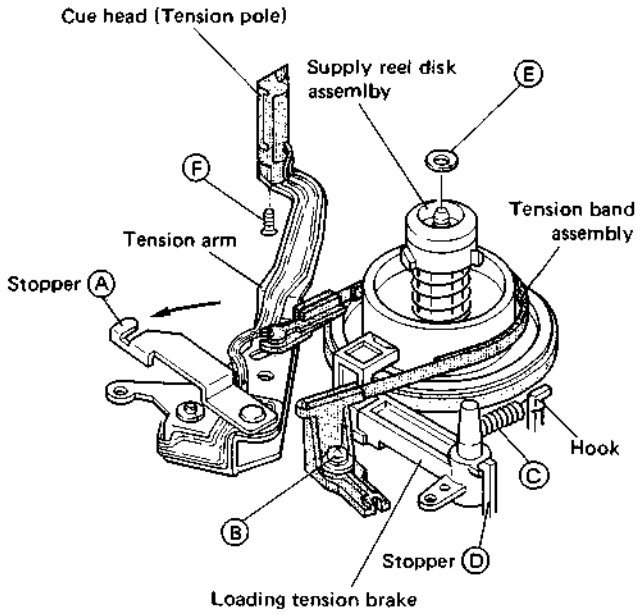

Fig. 4-17 Reel disk and tension band replacement

1. Slide stopper Ⓐ toward the left, then take out screw Ⓑ and remove the tension band assembly.
2. Unhook the spring Ⓒ, bend the stopper Ⓓ and remove the loading tension brake in the upward direction.
3. Take off the slit washer Ⓔ to replace the reel disk assembly. Use care regarding the washers when removing the reel disk assembly in the upward direction.
4. Reassemble by reversing the above steps. Apply a small amount of oil to the reel shaft.
5. To remove the cue head, unsolder the lead wires and take out screw Ⓕ. When replacing, use care regarding the mounting angle.
6. Perform the following checks and adjustments.

A: **Reel disk height**

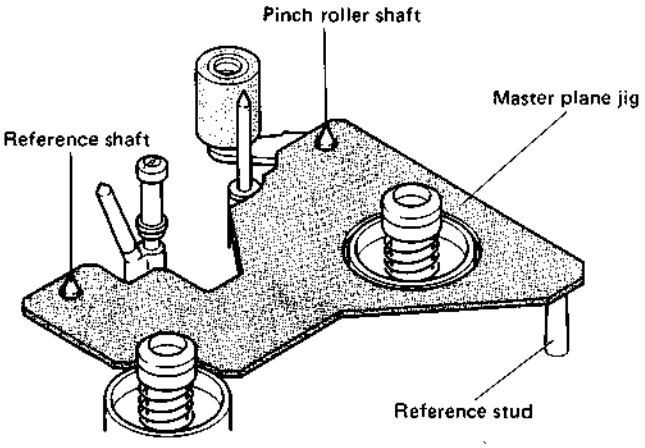

Fig. 4-18 Master plane jig setting

1. Set the master plane jig as shown in Fig. 4-18.

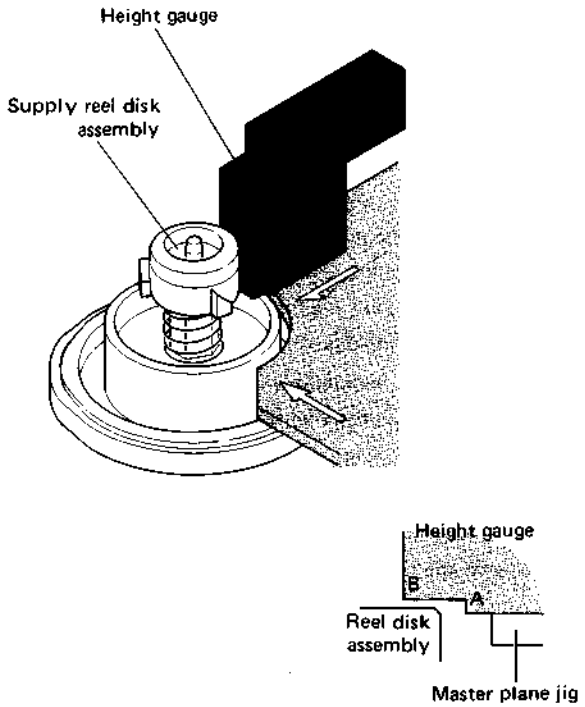

Fig. 4-19 Reel disk height adjustment

2. Use the height gauge to check the reel disk assembly height. Measure at two places 90° apart.
3. The correct height is between planes A and B as shown in Fig. 4-19.

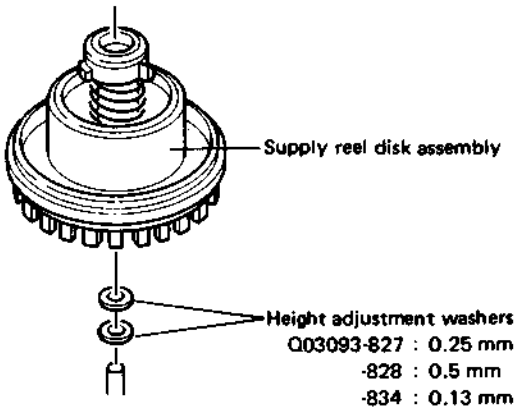

Fig. 4-20 Washers for height adjustment

4. If it is necessary to adjust the height, add or subtract the required number of height adjustment washers as shown in Fig. 4-20.
5. After reassembling, confirm a small amount of mechanical play between reel disk and slit washer.
6. Height adjustment is not required for the take-up reel disk.

B: **Cue head mounting angle**

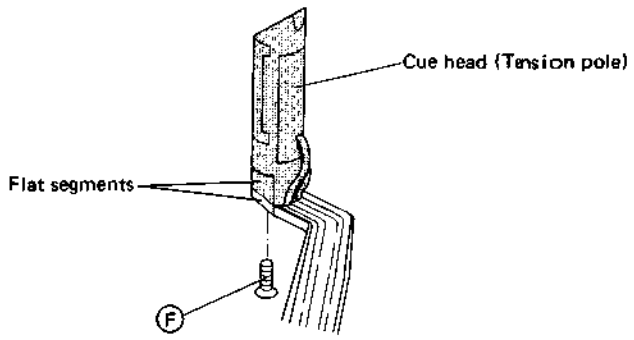

Fig. 4-21 Cue head mounting angle

1. Mount the cue head using screw Ⓕ, but do not tighten fully.
2. As shown in Fig. 4-21, align the flat segments of the cue head and tension arm, then tighten screw Ⓕ.

C: Tension pole (cue head) position

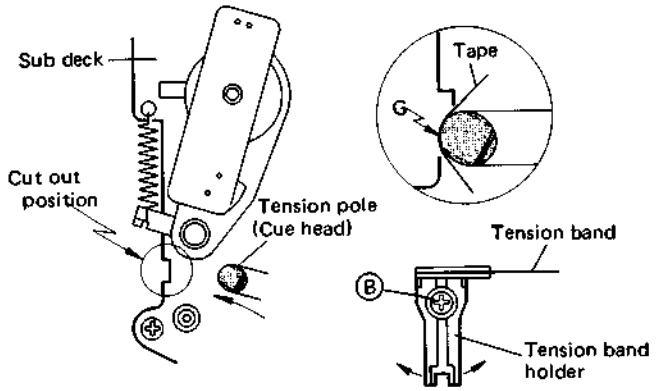

Fig. 4-22 Tension pole (cue head) position adjustment

1. While the tape is running, check that point G of the cue head (tension pole) is positioned within the 0.5 mm range shown in Fig. 4-22.
2. If necessary, loosen screw (B) and adjust the tension band holder to obtain the correct tension pole position.

   Note: If back tension is incorrect, check the tension pole position. Use the back tension cassette gauge and confirm a value of between 30 g to 40 g. If necessary, replace the back tension arm spring and re-adjust the tension pole position.

4.3.9 Pinch roller solenoid

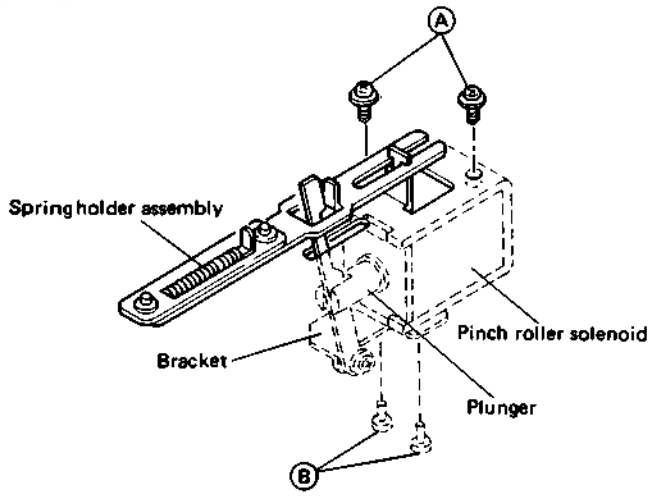

Fig. 4-23 Pinch roller solenoid replacement

1. Take out two screws (A) and remove the pinch roller solenoid.
2. Take out two screws (B), remove the solenoid bracket and replace the pinch roller solenoid (ordinarily, it is not necessary to replace the plunger).
3. Reassemble by reversing the above steps, but do not tighten screws (A) firmly at this time.
4. Without tape, supply power and set for the Play mode.

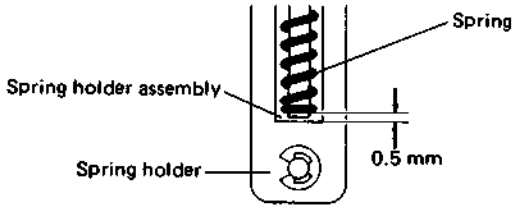

Fig. 4-24 Pinch roller solenoid adjustment

5. Adjust the solenoid mounting position for 0.5 mm space between the spring holder and spring as shown in Fig. 4-24. Then tighten the screws (A) firmly. This step adjusts pinch roller pressure.

4.3.10 Capstan flywheel and capstan FG board

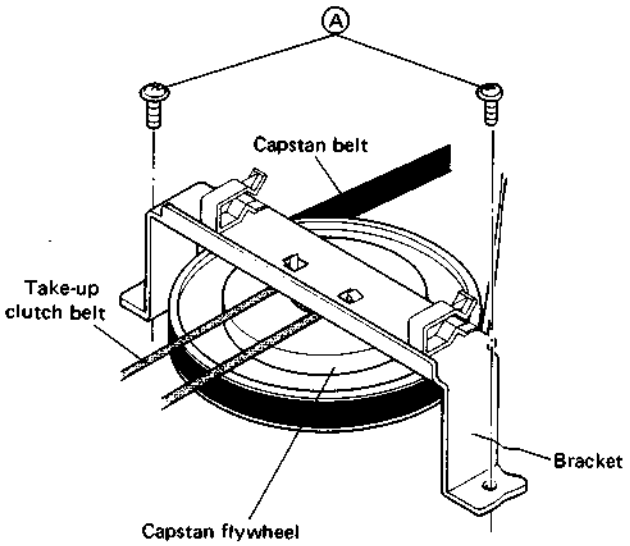

Fig. 4-25 Capstan flywheel replacement

1. Take out two screws (A) and remove the bracket. See Fig. 4-25.
2. Disengage the take-up clutch and capstan belts, then gently remove the capstan flywheel in the upward direction. At this time, use care not to misplace the capstan oil seal and spacer attached to the capstan.

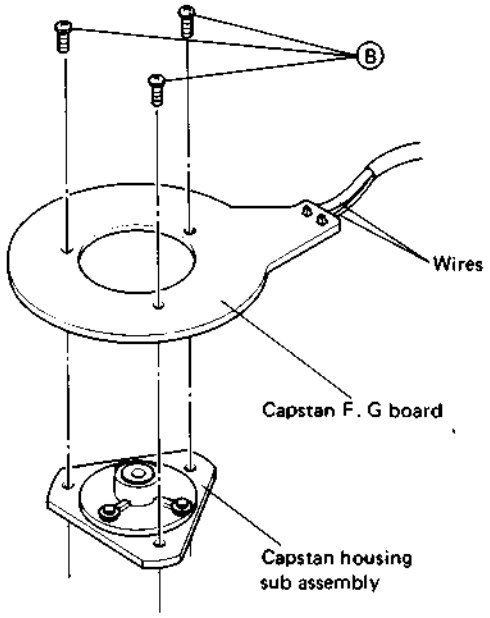

Fig. 4-26 Capstan F.G. board replacement

3. Take out three screws Ⓑ , indicated in Fig. 4-26, and remove the capstan FG board. Unsolder the lead wires.
4. Reassemble by reversing the above steps. After mounting the capstan flywheel, spacer and capstan oil seal, use alcohol to thoroughly clean the capstan.

4.4 TAPE TRANSPORT SYSTEM CHECKS AND ADJUSTMENT

The tape transport system has been precisely aligned at the factory and normally does not require readjustment. The following steps are therefore necessary only in cases of severe usage or when replacing parts affecting the tape transport system.

4.4.1 Tape transport check

1. Employ a 120-minute tape and check at tape beginning and ending portion according to the following steps.
2. Operate the machine between Play and Stop modes several times.
   During Loading and Unloading, observe the tape at the supply and take-up guide rollers and guide poles.
   Confirm absence of curling, wrinkling, etc. as shown in Fig. 4-27.

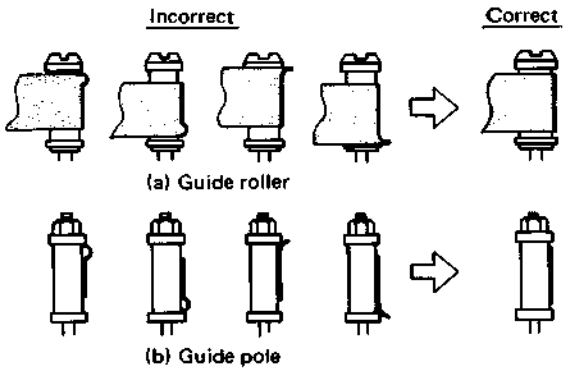

Fig. 4-27 Guide roller and guide pole

3. Observe the tape as it becomes wrapped around drum during loading and as it separates from the drum during unloading.
   Confirm absence of damage to the tape at points Ⓐ and Ⓑ as shown in Fig. 4-28 and absence of contact noise between head tips and tape edge.

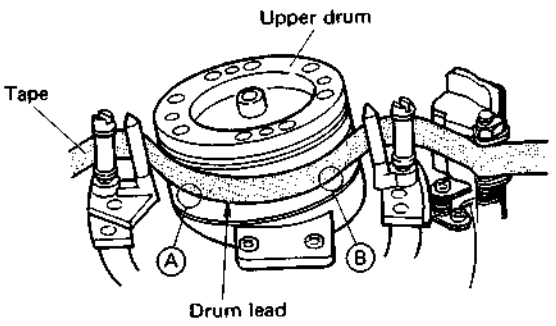

Fig. 4-28 Drum lead check-1

NOTES:

1. Slips upward : sound becomes produced by contact between tips of rotating heads and edge of tape.
2. Slips downward : tape curls or wrinkles from contacting lead face (sound may also be produced).

4. During Play mode, observe tape at the input and output portions (Ⓒ and Ⓓ in Fig. 4-29) of the head drum lead.
   Confirm that the tape slips neither upward nor downward with respect to the lead as shown in Fig. 4-30.

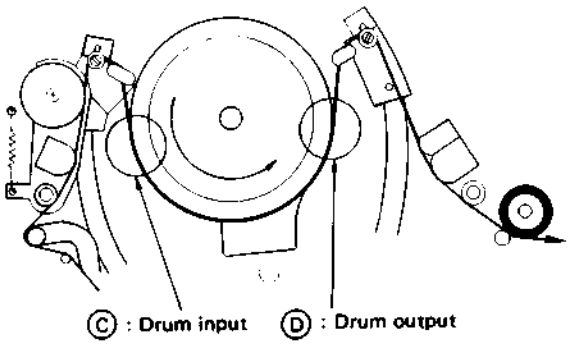

Fig. 4-29 Tape transport check

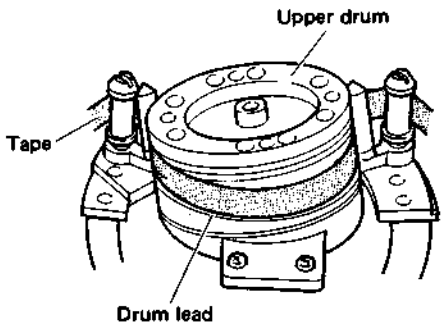

Fig. 4-30 Drum lead check - 2

5. During Play mode, observe the tape at the take-up and supply guide poles and guide rollers.
   Confirm absence of curling, wrinkling, etc. as shown in Fig. 4-27.
6. If defects are noted the above checks, perform the following adjustments.

4.4.2 Tope transport adjustments

Perform only if defects are noted during tape transport check (4.4.1).

A: Guide roller height adjustment

1. Slightly loosen setscrews of the supply and take-up guide rollers as shown in Fig. 4-31.
2. Use a cassette tape and set for Play mode.
3. With a slotted screwdriver, slightly turn the supply guide roller (do not turn more than 180° at a time) and adjust so that at the drum input, the tape travels smoothly in the drum lead without slipping upwards or downwards.
4. Similarly, adjust the take-up guide roller for the drum output.

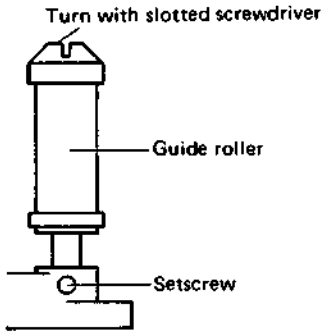

Fig. 4-31 Guide roller height adjustment

NOTES:

1. Loosen the setscrews only enough to allow the guide rollers to be turned.
   If excessively loose, tape motion may turn the rollers inadvertently.
2. Turn the rollers carefully to avoid damage to the tape.

B: Guide pole height adjustment

(a) Guide pole height check

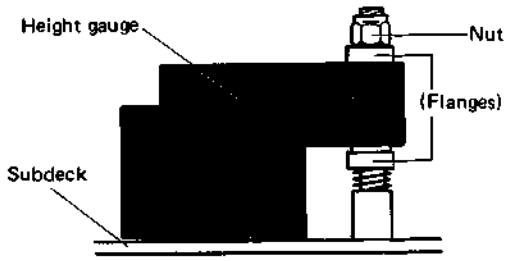

Fig. 4-32 Guide pole height adjustment

1. Set the height gauge on the subdeck as shown in Fig. 4-32.
2. For each guide pole, check the height of the lower face of the upper flange. If necessary, carefully adjust by turning the nut.
   After adjusting the height using the height gauge, turn the supply side nut 50° counter-clockwise and the take-up side nut 90° clockwise. This will provide the required slight difference in height between the supply and take-up guide poles.
3. If guide pole height has been adjusted, following checks and adjustments are required.

(b) Supply guide pole height adjustment

1. Use a cassette tape and set for Play mode.
2. Use a metric nutdriver to turn the supply guide pole to align the upper flange of the guide pole with the upper edge of the tape as shown by (b) of Fig. 4-27. However, this adjustment must be performed so that at the same time, the upper flange remains within ±0.5 mm of the height adjusting jig portion shown in Fig. 4-32.

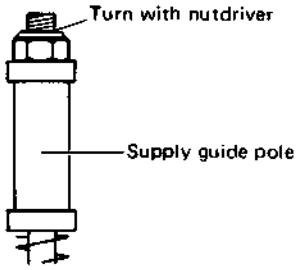

Fig. 4-33 Supply guide pole height adjustment

3. If there is a large discrepancy, check the height of the supply reel disk, tension pole and other mechanical components.

C: Audio/Control head adjustment

1. Employ a cassette tape and set for Play mode.
2. Turn audio/control head screw Ⓒ as shown in Fig. 4-34 and adjust for smooth transport at the take-up guide pole as shown by (b) of Fig. 4-27.

NOTE: Do not adjust the height of the take-up guide pole itself.

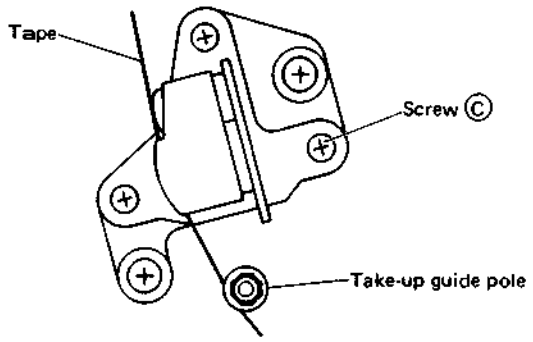

Fig. 4-34 Take-up guide pole

4.5 INTERCHANGEABILITY ADJUSTMENT

Before using alignment tape, employ a tape and confirm correct tape transport.

4.5.1 Preliminary checks

A: Check sequence 1

1. Connect oscilloscope to TP-106 of the Y & PRE/REC board. At this time, trigger the oscilloscope externally with the signal from TP-111 (DRUM F.F in) of the Y & PRE/REC board.
2. Play Stairstep portion of the alignment tape MH-2.
3. Turn the Tracking control and adjust for maximum FM output at TP-106.
   Set the Tracking control to AUTO (center click position) and confirm that nearly maximum output is obtained.

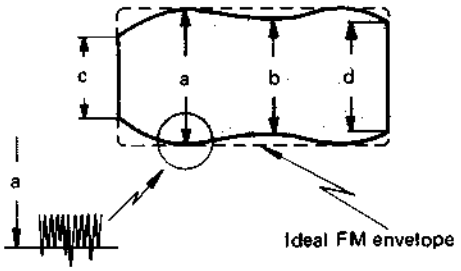

Fig. 4-35 FM waveform (max. output)

4. Refer to Fig. 4-35. Read the level of portion (a) of the waveform. If the waveform is serrated at point (a), read the value at the most uniform serrations as shown at left in Fig. 4-35.
5. Read the maximum FM level (a) and minimum FM level (b), and confirm that:

$$\frac{b}{a} \geqq 0.7 \text{ or } 20 \log \frac{b}{a} \geqq -3 \text{ dB}$$

6. Read the values at points (c) and (d) [drum input and output] and confirm that:

$$\frac{c}{a} \geqq 0.5 \text{ and } \frac{d}{a} \geqq 0.5 \ (\geqq -6 \text{ dB})$$

NOTES:
1. Read minimum levels for (b), (c) and (d).
2. If above checks yield normal results, proceed to section 4.5.1 - B.
3. If defects are noted, perform adjustments of section 4.5.2.

B: Check sequence 2

1. Observe the FM waveform as in the previous section (4.5.1 - A) and turn the Tracking control.
   The waveform variation should be nearly parallel as shown in Fig. 4-36.

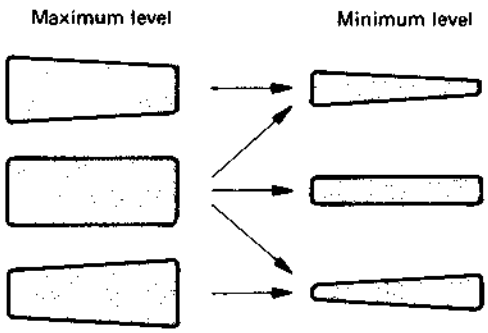

Fig. 4-36 Normal waveform examples

2. If the waveform varies as shown in Fig. 4-37, adjustment becomes required.

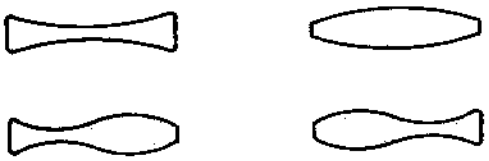

Fig. 4-37 Incorrect waveform examples

4.5.2 Preliminary adjustments

1. Loosen the setscrews of the supply guide roller and take-up guide roller.
   If the guide rollers turn freely, slightly tighten the set-screws.
2. Connect oscilloscope to TP-106 of the Y & PRE/REC board. Trigger the oscilloscope externally with the signal from TP-111 (DRUM F.F in) of the Y & PRE/REC board.
3. Play the alignment tape (stairstep signal) MH-2.

A: Drum input

1. Observe oscilloscope display and adjust the Tracking control for maximum FM output.
2. Refer to Fie. 4-38. Examples of incorrect waveforms are shown by A.
   Use a slotted screwdriver to adjust the supply guide roller so that the rising portion (drum input portion) of the waveform becomes flat as shown by B.

NOTES:

1. If the guide roller turns freely, tighten the setscrew slightly.
2. Be sure to adjust the guide roller only by small amounts at a time in order to avoid damaging the alignment tape.

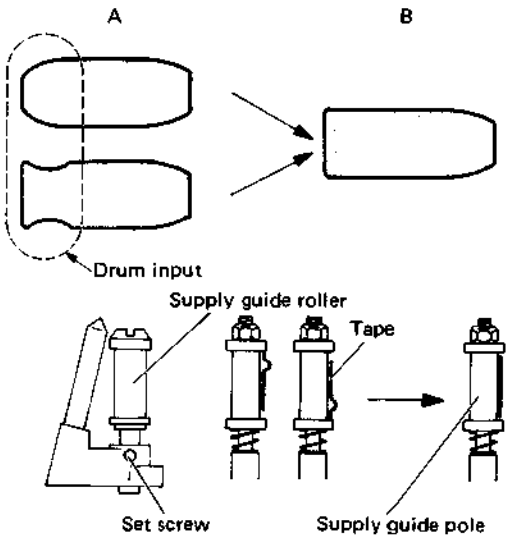

Fig. 4-38 Drum input adjustment

In addition to observing the waveform, confirm absence of tape slippage or curling at the drum lea and guide poles.

3. At the supply guide pole, if the tape separates fron the guide or wrinkling occurs, adjust the guide pol height.

B: Drum output

1. In the same manner as for the drum input, turn the take up guide roller to adjust the falling portion (drum out put portion) of the FM waveform.
   Incorrect examples are shown by Ⓒ in Fig. 4-39, whil Ⓓ indicates the correct adjustment.
2. If the tape separates from the guide or wrinkling occur at the take-up guide pole, adjust by turning screw Ⓒ o the audio/control head as shown in Fig. 4-39.

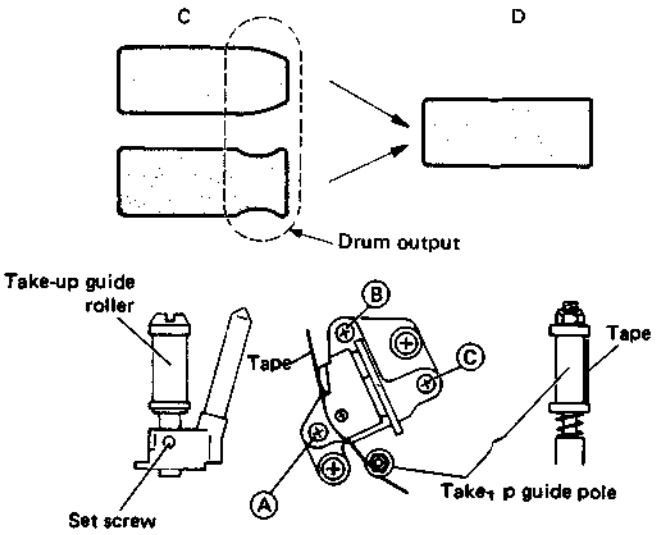

Fig. 4-39 Drum output adjustment

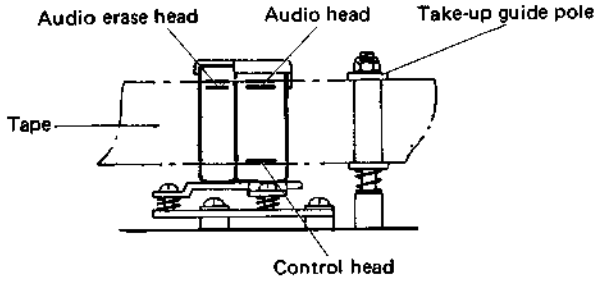

Fig. 4-40 Audio/Control head height

3. Carefully and evenly adjust screws Ⓐ, Ⓑ and Ⓒ to align the audio/control head height with the tape as shown in Fig. 4-40.

NOTES:

1. Fine adjustment is not required at this time.
   It is sufficient that the tape is engaged with the guide pole and servo operates stably (control signal picked up).
2. If the tape separates from the take-up guide pole or wrinkling occurs, screw Ⓒ (Fig. 4-39) has been turned excessively with respect to screws Ⓐ and Ⓑ, causing the audio/control head to incline forward or rearward. Use care to adjust screws Ⓐ, Ⓑ and Ⓒ evenly and observe that small wrinkles are not produced at the take-up guide pole.
3. Do not disturb the take-up guide pole.

4.5.3 Interchangeability fine adjustment

1. Connect oscilloscope to TP-106 of the Y & PRE/REC board. Play stairstep segment of the alignment tape MH-2. Observe the FM waveform and adjust the Tracking control for minimum FM output level.

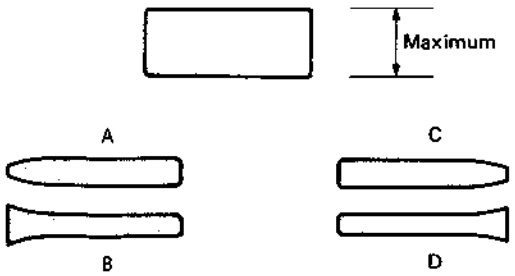

Fig. 4-41 Minimum FM output (incorrect examples)

2. If the waveform becomes as shown by A or B of Fig. 4-41, carefully adjust the supply guide roller height so that the waveform becomes as shown by E, F or G of Fig. 4-42.
   At this time, if the waveform fluctuates, adjust to the point of minimum fluctuation.

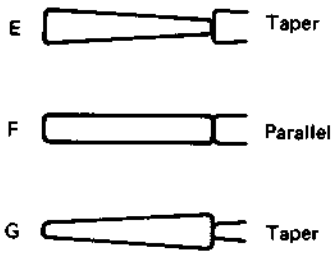

Fig. 4-42 Minimum FM output (correct examples)

3. If the FM waveform appears as shown by C or D in Fig. 4-41, carefully adjust the take-up guide roller height to obtain a waveform such as shown by E, F or G of Fig. 4-42.
   At this time, if the waveform fluctuates, adjust to the point minimum fluctuation.
4. Vary the Tracking control from maximum to minimum FM output.
   Perform fine adjustment of supply and take-up guide rollers so that waveform variation becomes as shown by E, F or G of Fig. 4-42.

4.5.4 Audio/Control head height, azimuth and inclination

See section 4.3.7-B Audio/Control head height and azimuth.

4.5.5 Setscrew tightening

1. Check for maximum FM output waveform, maximum audio out and absence of tape wrinkling or other transport irregularities, then secure the guide rollers.
   Perform in Stop mode.
2. Since the guide rollers are easily moved, use care when securing.
3. After tightening the setscrews, again perform interchangeability final check.

4.5.6 Interchangeability final check

Confirm section 4.5.1 Preliminary checks.

4.5.7 Servo circuit adjustment

1. Video head switching position (see section 5.4.7).
2. Tracking preset (see section 5.4.8).

4.5.8 Control head phase adjustment

1. Connect oscilloscope to TP-106 of the Y & PRE/REC board. Trigger the oscilloscope externally with the signal from TP-111 (DRUM F.F in) of the Y & PRE/REC board.
2. Play stairstep portion of the alignment tape MH-2 and observe the oscilloscope display.
3. Set the Tracking control to AUTO (center click position).

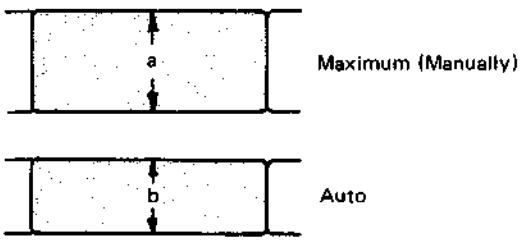

Fig. 4-43 FM output level

4. Confirm that the level difference between this setting and the maximum level obtained manually is:

$$-20 \log \frac{b}{a} \leqq 1 \text{ dB or } \frac{b}{a} \geqq 0.9$$

5. If necessary, adjust as follows.
6. Set the Tracking control to AUTO and play stairstep segment of the alignment tape MH-2.
7. Loosen two screws Ⓓ and Ⓔ and slide the A/C head assembly fully in the direction to the take-up guide pole.

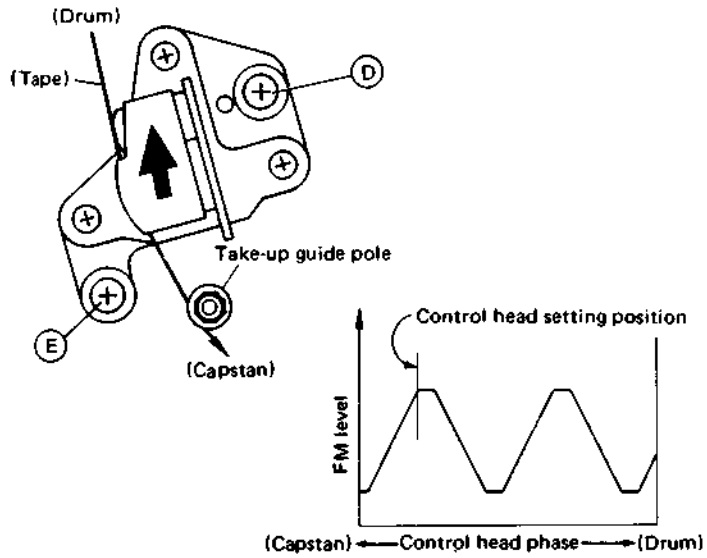

Fig. 4-44 Control head phase adjustment

8. Slightly tighten the two screws and play stairstep segment of the alignment tape MH-2.
9. Set the audio/control head position tool (PUJ47351-2) over the screw Ⓓ and insert the pin of the tool into the hole at the side of the screw.
10. Slowly turn the tool and slide the A/C head assembly in the direction of the arrow as shown in Fig. 4-44.
11. Set the A/C head assembly to the position where first maximum FM level is obtained. Tighten two screws Ⓓ and Ⓔ.

4.5.9 Final checks (recording and playback)

1. Use a blank tape and perform recording and playback. Confirm FM waveform and specifications equivalent to those during playback of alignment tape (stairstep signal). See section 4.5.1.
2. Perform checks and adjustments of the audio recording and playback levels. See section 5.6 Audio circuit.
3. Check other signal systems by referring to section 5 electronic adjustment.

SECTION 5
ELECTRICAL ADJUSTMENTS

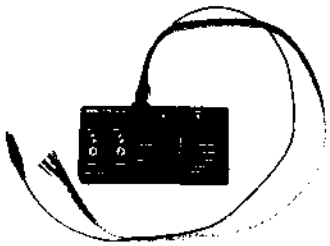
5.1 PREPARATION

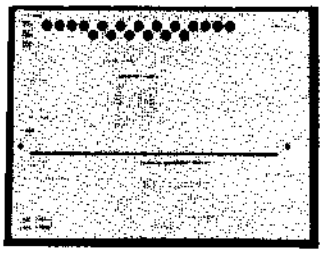
Electrical adjustments are required after replacing circuit components and certain mechanical parts. It is important to perform these adjustments only after all repairs and replacements have been completed. Also, do not attempt these adjustments unless the proper equipment is available.

Required test equipment and jigs

- Digital voltmeter : High sensitivity
- Oscilloscope : Wide-band, Dual-trace
- Signal generator : PAL-color bar and stairstep, SECAM-color bar NTSC-color bar
- Frequency counter : High sensitivity, High impedance
- Regulated DC power supply : 0 – 30 V
- Audio generator
- TV signal generator : With color bar and stairstep signal outputs

• JVC Alignment Tape MH-2 (PAL) and MH-5 (NTSC /SECAM)	• Servo TP jig PUJ43067	• Adjustment Template PUJ36331G	• Long shafted driver PUJ43620
			





NOTES: Be sure to check for smooth and proper tape transport before using the alignment tape.

IMPORTANT:

Even with the Sub-power switch off, DC voltage is supplied to the circuits. Therefore, set the rear panel MAINS POWER switch to off before performing service or replacing parts.

5.2 REGULATOR CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the REGULATOR board.

5.2.1 Regulated all 12V DC

1. Connect a digital voltmeter to TP2 (ALL 12V OUT) and set for the STOP (E-E) mode.
2. Adjust R15 (12V ADJ) for 12.0 ± 0.1 V DC.

5.2.2 Regulated 12V DC for CAMERA connector

1. Set the REC SELECT switch to CAMERA mode.
2. Connect a digital voltmeter to CONN. 32 (12V OUT) and set for the STOP (E-E) mode.
3. Confirm that the DC voltage is 13.0 ± 1.0 V.

5.2.3 Drum 12V DC

1. Connect a digital voltmeter to CONN. 84 (DRUM 12V OUT) and set for the STOP (E-E) mode.
2. Confirm that the DC voltage is 13.0 ± 1.0V.

5.2.4 Unregulated 22V DC

1. Connect a digital voltmeter to TP3 (UNREG 22V OUT) and set for the STOP (E-E) mode.
2. Confirm that the DC voltage is 23.0 ± 3.0V.

5.2.5 Switched 12V DC

1. Connect a digital voltmeter to CONN. 83 (SW 12V OUT) and set for the STOP (E-E) mode.
2. Confirm that the DC voltage is 12.0 ± 0.2 V.

5.3 TUNER/TIMER SUB CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the T/T (Tuner/Timer) SUB board.

Set for the STOP (E-E) mode.

5.3.1 3V AC

1. Connect a digital voltmeter between CONN. 122 and 123.
2. Confirm that the AC voltage is 3.0 ± 0.3 V.

5.3.2 −24V DC

1. Connect a digital voltmeter to CONN. 124.
2. Confirm that the DC voltage is −24 ± 1 V.

5.3.3 44V AC

1. Connect a digital voltmeter to CONN. 125.
2. Confirm that the AC voltage is 44 ± 6 V.

5.3.4 Back-up 5 V

1. Connect a digital voltmeter to CONN. 126.
2. Confirm that the DC voltage is 5.1 ± 0.4V.

5.3.5 30V REG.

1. Connect a digital voltmeter to CONN. 127.
2. Adjust R298 (30V REG ADJ) for 30.6 ± 0.1V DC.

5.4 SERVO CIRCUIT

NOTES:

1. Use the SERVO TP JIG for checkes and adjustments of the servo circuit.
2. Servo circuit test points we mainly formed by the 10 pin socket on the upper surface of the set (near the upper drum). Therefore connect the 10 pin plug of the SERVO TP JIG to this socket and the earth plug of the jig to the sub chassis earth terminal as indicated in Fig. 5-1.
3. Be sure to set the rear panel MAINS POWER switch to OFF before connecting the SERVO TP JIG.
4. Adjustments are performed by inserting an insulated alignment tool into the guide tubes located on the chassis.
5. Where not otherwise noted, test points and variable resistors are located on the SERVO board.

IMPORTANT:

Check that the Sub-power switch is on before measuring voltages at IC3 and IC12. These devices can be damaged if measurement is performed with power off.

5.4.1 Preparation

A. SERVO TP JIG

1. Engage the 10 pin plug of the jig with the 10 pin socket of the set. Connect the earth plug of the jig to the sub chassis earth terminal as indicated in Fig. 5-1.
2. Connect the oscilloscope probe to the TP and GND terminals of the jig. By using the selector switch, 9 waveforms can be observed.
3. When not otherwise noted, set the CAP. DISCRI and DRUM DISCRI switches to the NORMAL positions.
4. With either the CAP. DISCRI or DRUM DISCRI switch in the NORMAL position, LED lighting according to mode becomes as shown in Table 5-1.

MODE	LED States	
	CAP DISCRI	DRUM DISCRI
Stop (E-E)	Lights	Lights dimly
Play or REC (Loading complete)	Extinguishes	Extinguishes
Search REW or FF	Lights	Lights dimly
Discriminator mode	Lights	Lights

Table 5-1 LED Lighting

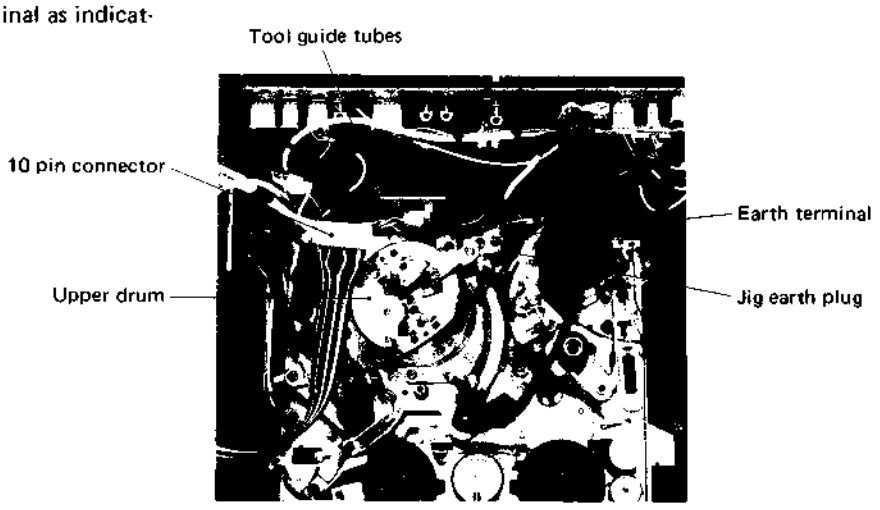


Fig. 5-1 Servo test poins and tool guide tubes

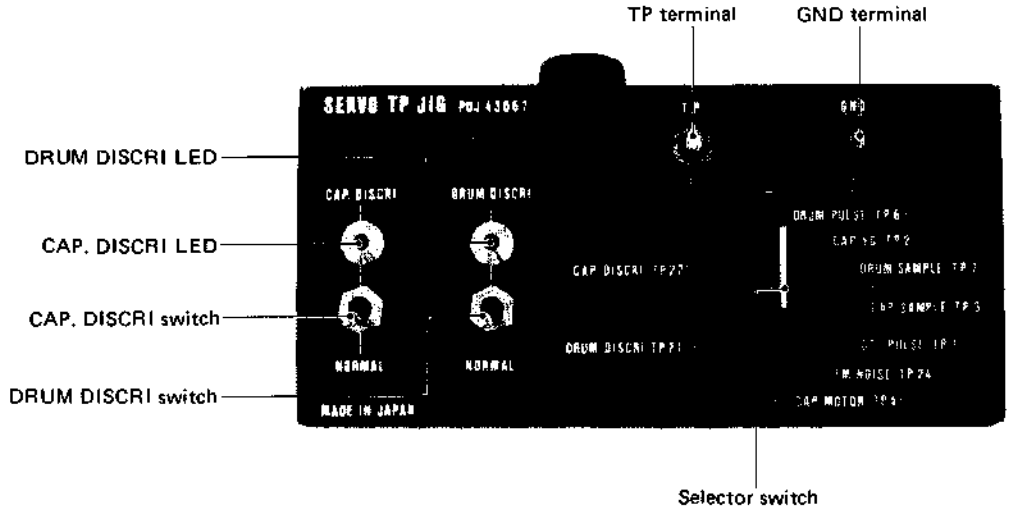

Fig. 5-2 SERVO TP JIG

B: Adjustment Template

1. The adjustment template is available for convenience in identifying the variable resistors when adjusting the Servo board.
2. The template is used for the top side of the set.
3. Use 2 screws (A) of the cassette housing to hold the template in place as shown in Fig. 5-3.
4. When adjusting the Servo circuit, employ a long shafted screwdriver. Insert it into the appropriate guide tube and carefully turn the control.

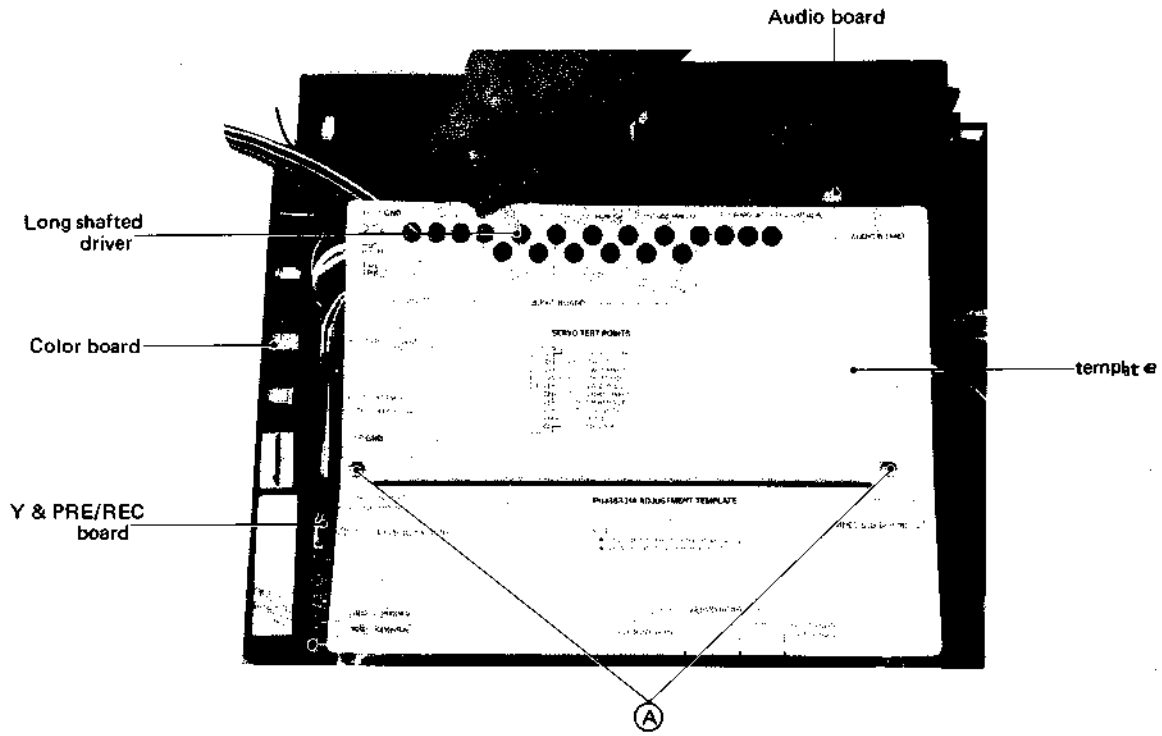

Fig. 5-3 Adjustment template

5.4.2 Drum pulse level

1. Play color bar segment of JVC MH-2 alignment tape.
2. Set the selector switch of the jig to DRUM PULSE (TP-6) position.
3. Adjust R56 that (a) and (b) become 0.75 ± 0.2 V.

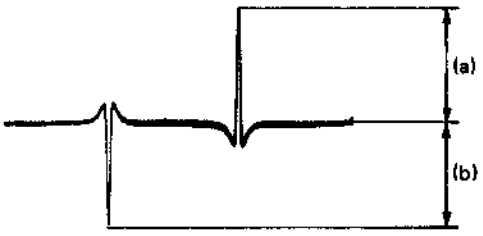

Fig. 5-4 Drum pick up pulse

5.4.3 Drum discriminator center

1. Supply a NTSC color bar signal and set for the recording mode.
2. Set the selector switch of the jig to DRUM SAMPLE (TP-7) and the DRUM DISCRI switch to ON (DRUM DISCRI LED lights).
3. Adjust R102 to stabilize the sampling pulse with respect to the trapezoid. At this time, a slow drift toward the left at the rate of less than 40 msec in 5 seconds is acceptable.
4. Set the jig DRUM DISCRI switch to NORMAL and confirm a stable sampling pulse positioned at the center of the ramp.
5. Supply a PAL color bar signal and set the recording mode.
6. Perform the step 2.
7. Adjust R100 to stabilize the sampling pulse with respect to the trapezoid. At this time a slow drift toward the left at the rate of less than 33 msec in 5 seconds is acceptable.
8. Perform the step 4.

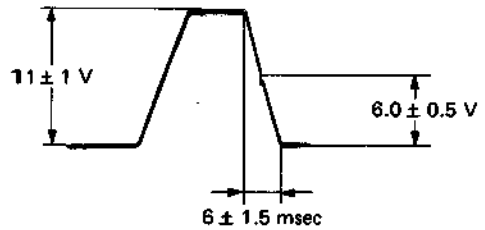

Fig. 5-5 Drum sampling

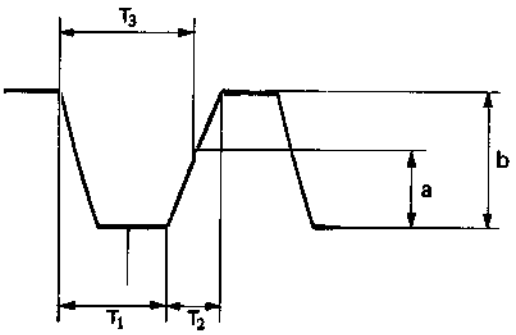
5.4.4 Capstan discriminator center

1. Supply a PAL color bar signal and set for the recording mode.
2. Set the jig selecter switch to CAP. SAMPLE (TP-3) and the CAP. DISCRI switch to ON (CAP. DISCRI LED lights).
3. Adjust R14 to stabilize the sampling pulse with respect to the trapezoid. At this time, a slow leftward drift at the rate of less than 40 msec in 5 seconds is acceptable.
4. Set the jig CAP. DISCRI switch to NORMAL and confirm a stable sampling pulse positionded at the center of the ramp (T_3 = 24 ± 1.5 msec).
5. Supply a NTSC color bar signal and set for the recording mode.
6. Perform the step 2.
7. Adjust R12 to stabilize the sampling pulse with respect to the trapezoid. At this time, a slow leftward drift at the rate of less than 33 msec in 5 seconds is acceptable.
8. Perform the step 4.



PAL
- a = 6 ± 0.5 V
- b = 11 ± 1 V
- T_1 = 20 ± 1.5 msec
- T_2 = 9.5 ± 1.5 msec

NTSC
- a = 6 ± 0.5 V
- b = 11 ± 1 V
- T_1 = 16.7 ± 1.5 msec
- T_2 = 9.5 ± 1.5 msec

Fig. 5-6 Capstan sampling

5.4.5 Video head switching position

A: Playback switching position

1. Play stairstep segment of JVC MH-2 alignment tape and set the tracking VR to center clik position.
2. Trigger the oscilloscope externally with the signal form TP-111 (DRUM F.FLOP) on the Y & PRE/REC board and set the oscilloscope sync slope to minus (−).
3. Connect the oscilloscope to TP-1 (VIDEO OUT) of the REAR CONNECTOR board and adjust R61 so that the fall portion of the vertical sync signal becomes positioned 6.5 H of the trigger (switching) point as shown in Fig. 5-7.

4. Set oscilloscope sync slope to pulse (+). In this condition, adjust R58 to obtain 6.5 H position.

B: Recording switching position

5. Supply a PAL color bar signal and set for the recoding mode.
6. In same manner as above step 2, 3 adjust R73 to obtain 6.5 H position at TP-1 (VIDEO OUT) of the REAR CONNECTOR board.

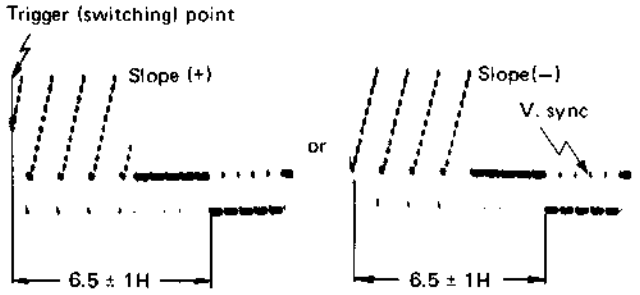


Fig. 5-7 Head switching position

5.4.6 Tracking preset

1. Supply a PAL color bar signal, record, then playback in the double-speed (X2) mode.
2. Set the tracking VR to AUTO (center clik position).
3. Adjust R40 to obtain the best picture on the TV monitor.
4. Supply a NTSC color bar signal, record then playback.
5. Set the jig selector switch to CTL. PULSE (TP-1).
6. Connect the second probe of the oscilloscope to TP-111 (DRUM F.F.) fo the Y & PRE/REC board. Observe the two waveforms at the same time and adjust R42 for T = 0.5 ± 1 msec in the Fig. 5-8.

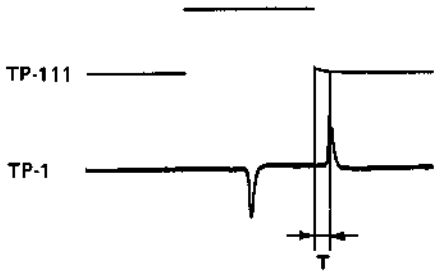

Fig. 5-8 Tracking preset

5.4.7 Slow pulse width

1. Supply a NTSC color bar signal, record, then playback in slow mode.
2. Set the jig selector switch to CAP. MOTOR (TP-4).
3. Adjust R32 for T = 58 msec as shown Fig. 5-9.
4. Supply a PAL color bar signal, record, then playback in slow mode.
5. Adjust R35 for T = 63 msec in Fig. 5-9.

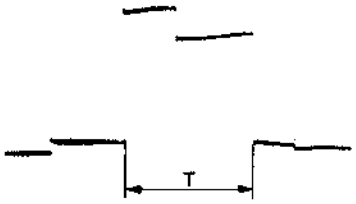

Fig. 5-9 Slow pulse

5.4.8 Slow tracking pre-set

1. Supply a SECAM color bar signal, record, then playback in slow mode.
2. Set the SLOW TRACKING VR to center click position.
3. Adjust R137 to obtain the best picture on the TV monitor.
4. Supply a NTSC color bar signal, record, then playback in slow mode.
5. Adjust R136 to obtain the best picture on the TV monitor.

5.4.9 FM noise pulse width

1. Supply a SECAM color bar signal, record, then playback in STILL mode.
2. Set the jig selector switch to FM NOISE (TP-24).
3. Adjust R141 for T = 10^{+5}_{-3} msec in the Fig. 5-10.

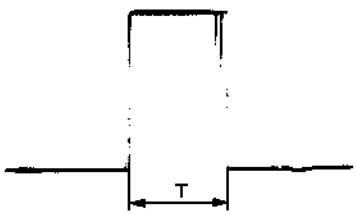

Fig. 5-10 FM noise pulse

5.4.10 Vertical pulse

1. Supply a SECAM color bar signal, record, then playback in STILL mode.
2. Trigger the oscilloscope externally with the signal from TP-111 (DRUM F.FLOP) of the Y & PRE/REC board and set the oscilloscope trigger slope to plus (+).
3. Connect oscilloscope to VIDEO OUT of the REAR CONNECTOR board.
4. Adjust R65 for T = 2.5 H in the Fig. 5-11.
5. Observe the picture dispaly and adjust R68 for minimum vertical jitter.

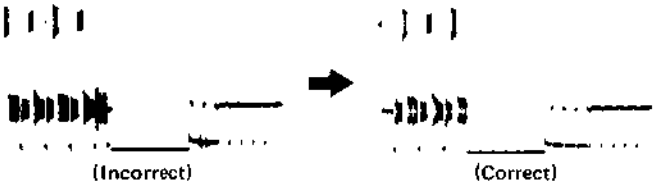

Fig. 5-11 Vertical pulse

5.4.11 Shuttle search H discriminator

1. Play SECAM color bar segment of JVC MH-5 alignment tape.
2. Connect oscilloscope to TP-521 of the COLOR board.
3. Set the trigger slope to pulse (+) and synchronize the oscilloscope with the rising component of the waveform in the Fig. 5-12.

Fig. 5-12 H. sync signal

4. Set the front porch (point A) of the waveform to the center of the oscilloscope display, expand the waveform X5 (five times) and again center point A.
5. In the shuttle search FF mode, adjust R107 to position the front porch of the H sync waveform at point A (within ± 0.5 μsec). See Fig. 5-13.
6. Confirm the same value for the shuttle search REW mode.

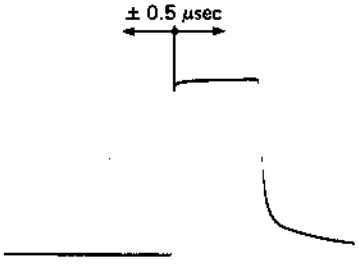

Fig. 5-13 H. discriminator

5.5 VIDEO CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the Y & PRE/REC, COLOR and and NTSC COLOR boards.

A: Playback system

[Y . . . Luminance signal]

5.5.1 Video head resonance, Q (quality factor) and FM equalizer

Note: This adjustment is generally unnecessary except when replacing the upper drum assembly.

– Factory service –

1. Set the SYSTEM SELECT switch to the PAL (MANUAL) position.
2. Apply the sweep signal from a video sweep generator to TP-222 (CH-1 REC OUT).
   Insert 1.0 MHz and 5 MHz markers.
3. Without inserting tape, set for Play mode. Then adjust the sweep gain so that the waveform does not distort at TP-106 (PB FM).
4. At TP-106, adjust C200 (CH-1 RESO) for maximum level at the 5 MHz marker portion.
5. Adjust R231 (CH-1 Q) so that the 5 MHz level becomes 2.5 times of the 1.0 MHz.

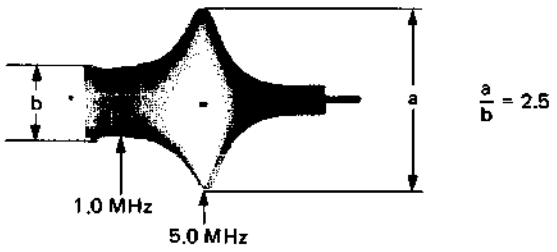

Fig. 5-14 Video head resonance and Q

6. In the same manner, adjust for CH-2. Apply sweep to TP-223 (CH-2 REC OUT) and adjust C202 (CH-2 RESO) and R232 (CH-2 Q).
7. Set the rear panel MODE SELECT SWITCH to B/W. Supply a video sweep signal with the sync signal, record then playback. Insert 100 kHz and 2 MHz markers.
8. At TP-00 (VIDEO OUT) measure earch 2 MHz level for CH-1 and CH-2 outputs. Adjust Q control (R231 and R232) of the lower level channel for equal level at both channels.
9. Adjust R153 (FM EQ) so that the 2 MHz level becomes 70% of the 100 kHz.

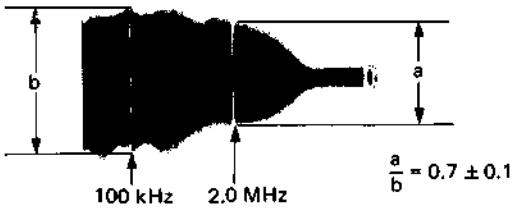

Fig. 5-15 Playback FM equalizer

— Non-factory service —

1. Play RF sweep segment of JVC MH-2 alignment tape. Trigger the oscilloscope externally with the drum flip-flop signal from TP-111 (DRUM F.FLOP).
2. Monitor TP-106 (PB FM) and turn R231 (CH-1 Q) and R232 (CH-2 Q) fully counter clockwise in order to boost the highband frequency component.
3. Set the oscilloscope sync slope to minus (—) and adjust C200 (CH-1 RESO) to set the CH-1 resonance point to 5.0 MHz marker portion.
4. Set the oscilloscope sync slope to plus (+) and adjust C202 (CH-2 RESO) to set the CH-2 resonance point to 5.0 MHz.

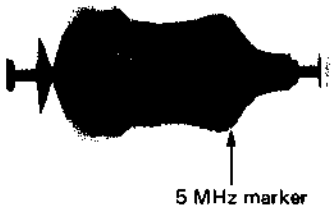

Fig. 5-16 Video head resonance (with alignment tape)

5. Set R231 and R232 (HEAD Q) to mechanical center.
6. Measure each 5 MHz FM level for CH-1 and CH-2 at TP-106 and adjust Q control (R231 or R232) of the lower level channel for equal level at both channels.

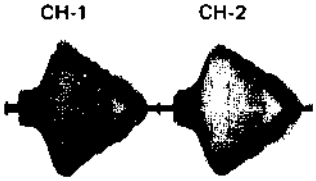

Fig. 5-17 Video head Q (with alignment tape)

7. Record an off-the-air signal, then playback. While observing the picture, adjust R153 (FM EQ) for optimum clarty. (This adjusts the sharpness and softness of the playback picture.)

5.5.2 Noise canceller

1. Connect a 0.022 μF capacitor between TP-1 and TP GND of the VIDEO SUB board.
2. Play color bar segment of JVC MH-2 alignment tape.
3. At TP-1 (NOISE CLIP), adjust R11 (NOISE CANCEL to minimize the output level.
4. Remove the capacitor between TP-1 and TP-GND.

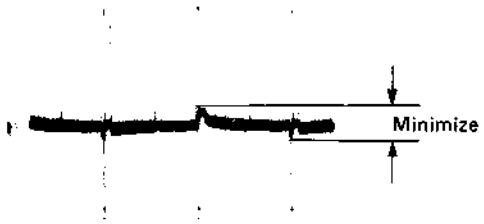

Fig. 5-18 Noise canceller

5.5.3 Playback Y level

1. Play color bar segment of JVC MH-2 alignment tape.
2. Adjust R101 (PB Y LEVEL CCIR) for 1.9 Vp-p at TP-1 (VIDEO OUT) of the REAR CONN. board without load as shown in Fig. 5-19.
3. Play NTSC color bar segment of JVC MH-5 alignment tape.
4. Adjust R105 (PB Y LEVEL NTSC) for 1.9 Vp-p at TP-1 (VIDEO OUT) of the REAR CONN. board without load as shown in Fig. 5-19.

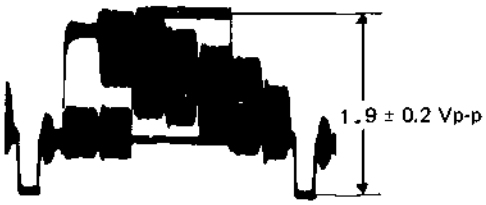

Fig. 5-19 PB Y level

[Color signal]

5.5.4 Playback subcarrier oscillator

1. Set the SYSTEM SELECT switch for NTSC (MODE position.
2. Play NTSC color bar segment of JVC MH-5 alignment tape and connect a frequency counter to TP-603.
3. Adjust R611 for 4.433619 MHz ± 50 Hz.

5.5.5 PAL AFC (Automatic Freqency Control)

1. Set the SYSTEM SELECT switch for AUTO position.
2. Supply a PAL color bar signal and set for the STOP (E-E) mode.
3. Connect a 680Ω resistor between TP-603 and TP-622.
4. Connect a freqency counter to TP-612 and adjust R624 for 625 kHz ± 2 kHz.
5. Remove a resistor between TP-603 and TP-622.

5.5.6 PAL VXO (Variable Crystal Oscillator)

1. Supply a PAL color bar signal and set for the STOP (E-E) mode.
2. Connect a frequency counter to TP-612.
3. Adjust C602 for 4.435571 MHz ± 50 Hz.

5.5.7 NTSC AFC (Automatic Frequency Control)

1. Set the SYSTEM SELECT switch for NTSC (STD.) position.
2. Supply a NTSC color bar signal and set for the STOP (E-E) mode.
3. Connect a 680Ω resistor between TP-403 and TP-422.
4. Connect a frequency counter to TP-412 and adjust R491 for 629 kHz ± 2 kHz.
5. Remove the resistor between TP-403 and TP-422.

5.5.8 NTSC VXO (Variable Cyrstal Oscillator)

1. Play NTSC color bar segment of JVC MH-5 alignment tape.
2. Connect a frequency counter to TP-403.
3. Adjust R408 for 3.579545 MHz ± 50 Hz.

B: Recording system

[Y . . . Luminance signal]

5.5.9 Carrier and deviation

NOTE: These adjustments are generally unnecessary except when replacing IC106 or IC107. Before adjustment, turn R216 (WHITE CLIP) and R219 (DARK CLIP) fully counterclockwise.

1. Supply a PAL color bar signal and set for the STOP (E-E) mode.
2. Connect oscilloscope to IC107 pin 18 and precisely measure the DC potential of the sync tip. Make a note of this as voltage "A".

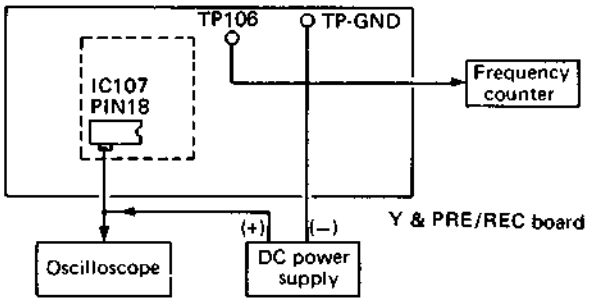

Fig. 5-20 Carrier and deviation

3. Connect a DC power supply between IC107 pin 18 and ground. Without an input signal, set for the STOP (E-E) mode and precisely apply sync tip bias "A" as observed with the oscilloscope.
4. Connect a frequency counter to TP-106 (REC FM IN) and adjust R291 (CARRIER) for 3.8 MHz $^{+0}_{-50}$ kHz.
5. Supply a NTSC color bar signal set for the STOP (E-E) mode.
6. Similarity apply sync tip bias "A" as observed with the oscilloscope.
7. Adjust R293 for 3.4 MHz ± 30 kHz.
8. Carefully adjust the DC power supply to obtain 4.4 MHz ± 30 kHz at TP-106 (REC FM IN). Precisely read the voltage of IC107 pin 18 with the oscilloscope. Make a note of this as voltage "B".
9. Disconnect the DC power supply. Supply a color bar signal and set for the STOP (E-E) mode.
10. Adjust R203 (DEVIATION) so that the white peak at IC205 pin 18 becomes equal to voltage "B".
11. About step 8, 9, 10, f = 4.8 MHz $^{+0}_{-50}$ kHz, set the input signal PAL color bar and adjust R201 like the above example.

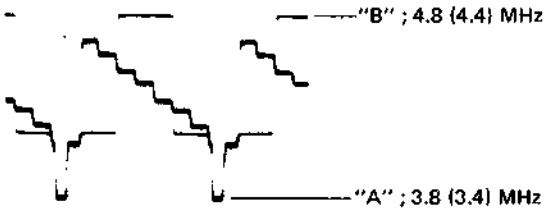

Fig. 5-21 FM modulation

5.5.10 White and dark clip

1. Supply a PAL color bar signal and set for the STOP (E-E) mode.
2. At TP-103 (W/D CLIP OUT), with the rated signal level taken as 100%, adjust R216 (WHITE CLIP) so that the white peak overshoot becomes 80% as shown in Fig. 5-22.
3. In the same condition, adjust R219 (DARK CLIP) so that the sync tip undershoot becomes 40%.

White clip
a : b = 1 : 0.8 ± 0.02
Dark clip
a : c = 1 : 0.4 $^{+0.05}_{-0}$

Fig. 5-22 White and dark clip

5.5.11 Recording FM level

1. Supply a NTSC color bar signal and set for the Recording mode.
2. Adjust R249 so that the pedestal level of the vertical blanking component becomes 4.4 V at TP222 or TP-223 of the VIDEO HEAD board.
3. Supply a PAL color bar signal and set for the recording mode.
4. Similarity adjust R251 that the pedestal level becomes 3.8 V.

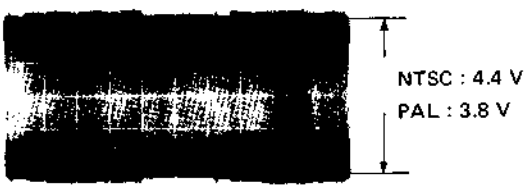

Fig. 5-23 Recording FM level

5.5.12 E-E video level

1. Supply a PAL color bar signal and set for the STOP (E-E) mode.
2. Adjust R189 (E-E LEVEL) for 1.9 Vp-p at TP-1 (VIDEO OUT) of the REAR CONNECTOR board without load.

Fig. 5-24 E-E video signal

[Color signal]

5.5.13 PAL Recording color level

1. Play color bar segment of JVC MH-2 alignment tape and connect oscilloscope to TP-604.
2. Measure the average of CH-1 output "a" and CH-2 output "b". See Fig. 5-25. Make a note of this as level "c".

$c = \frac{a + b}{2}$

Fig. 5-25 PAL Recording color level

3. Supply a PAL color bar signal, record, then playback.
4. During recording, adjust R671 so that during playback, the average of CH-1 output and CH-2 output becomes 100% with respect to level "c" at TP-604, i.e., adjust during recording and check during playback.

5.5.14 PAL converter valance

1. Supply a PAL color bar signal, record, then playback.
2. Connect oscilloscope to TP-621.
3. Adjust R621 for minimum leakage of the 5.1 MHz component.

Fig. 5-26 PAL converter valance

5.5.15 PAL PB burst level

1. Supply a PAL color bar signal, record, then playback.
2. Connect oscilloscope to TP-1 (VIDEO OUT) of the REAR CONNECTOR board.
3. Adjust R616 for 0.5 ± 0.04 V of burst signal without load.

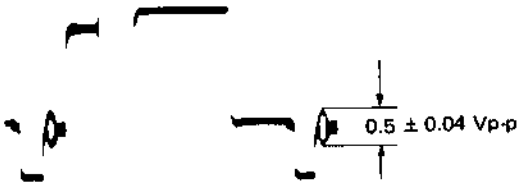

Fig. 5-27 PAL PB burst level

5.5.16 REC input bell

1. Supply a SECAM color bar signal and set for the STOP (E-E) mode.
2. Adjust L501 for minimum amplitude difference between (a) and (b) at TP-501 as shown Fig. 5-28.

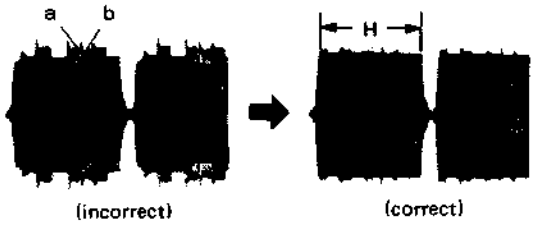

Fig. 5-28 REC input bell

5.5.17 REC output bell

1. Supply a SECAM color bar signal and set for the STOP (E-E) mode.
2. Adjust L502 so that the amplitude of line (n) violet and line (n + 1) violet are equal to each other at TP-502 as shown Fig. 5-30.

Fig. 5-29 REC output input bell

5.5.18 SECAM recording color level

1. Play SECAM color bar segment of JVC MH-5 alignment tape and connect oscilloscope to TP-501.
2. Measure the average of CH-1 output "a" and CH-2 output "b". See Fig. 5-30. Make a note of this as level "c".

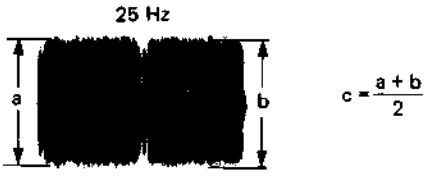

Fig. 5-30 SECAM recording color level

3. Supply a SECAM color bar signal, record, then playback.
4. During recording, adjust R545 so that during playback, the average of CH-1 output and CH-2 output becomes 140 ± 10% with respect to level "c" at TP-501, i.e., adjust during recording and check during playback.

5.5.19 SECAM playback color level

1. Supply a SECAM color bar, record, then playback.
2. Connect oscilloscope to TP-1 (VIDEO OUT) of the REAR CONNECTOR board.
3. Adjust R543 to obtain a violet level of 0.4 V without load.

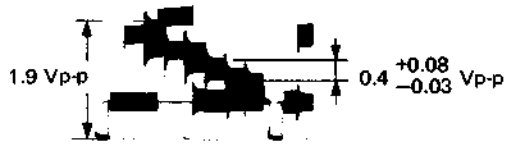

Fig. 5-31 SECAM playback color level

5.5.20 SECAM detector-1

1. Set the SYSTEM SELECT switch for SECAM (STD.) position.
2. Play SECAM color bar segment of JVC MH-5 alignment tape.
3. Adjust R554 for 6.0 ± 0.5 VDC at TP-522.

5.5.21 SECAM detector-2

1. Set the SYSTEM SELECT switch for SECAM (MODF.) position.
2. Supply a SECAM color bar signal, record, then palyback.
3. Adjust R683 for 6.0 ± 0.5 VDC at TP-623.

5.5.22 NTSC recoring color level

1. Play NTSC color bar segment of JVC MH-5 alignment tape and connect oscilloscope to TP-404.
2. Measure the average of CH-1 output "a" and CH-2 output "b". See Fig. 5-32. Make a not of this as level "a".

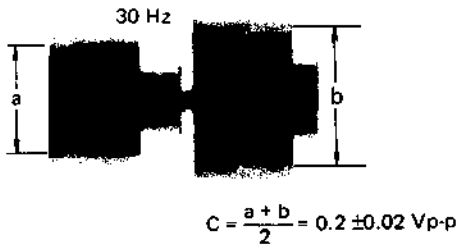

Fig. 5-32 NTSC recording color level

3. Supply a NTSC color bar signal, record, then playback.
4. During recording, adjust R452 so that during playback, the average of CH-1 output and CH-2 output becomes 100% with respect to level "c"at TP-404, i.e., adjust during recording and check during playback.

5.5.23 NTSC converter valance

1. Supply a NTSC color bar signal, record, then playback.
2. Connect oscilloscope to TP-421.
3. Adjust R404 for minimum leakage of the 4.2 MHz compornent.

Fig. 5-33 NTSC converter valance

5.5.24 NTSC playback burst level

1. Supply a NTSC color bar signal, record, then playback.
2. Connect oscilloscope to TP-1 (VIDEO OUT) of th REAR CONNECTOR board.
3. Adjust R700 for 0.54 ± 0.1 V of burst signal withou load.

Fig. 5-34 NTSC playback burst level

5.6 AUDIO CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the AUDIO board.

5.6.1 Playback level

1. Play 1 kHz audio signal segment of JVC MH-2 alignment tape.
2. Adjust R70 (PLAY LEVEL) for −6 ± 1 dBs at AUDIO OUT terminal (CONN. 42).

5.6.2 Bias level

1. Set for the Recording mode without signal.
2. Connect a digital voltmeter between CONN. 112 and CONN. 111 on the AUDIO/CTL HEAD board.
3. Adjust R125 for 2.0 ± 0.1 mV (RMS).

5.6.3 Recording level and equalizer

1. Set the SYSTEM SELECT switch to the PAL (MANUAL) position.
2. Supply a PAL video signal and a 1 kHz audio signal at −20 dBs and record, then playback.
3. During recording, adjust R93 (REC LEVEL CCIR) to obtain −6 ± 1 dBs at AUDIO OUT terminal during playback, i.e., adjust during recording and check during playback.
4. Supply 1 kHz and 10 kHz audio signals at −30 dBs and record, then playback.
5. During recording, adjust R95 (REC EQ CCIR) so that during playback, 10 kHz level becomes $^{+0}_{-3}$ dB of the 1 kHz level at the AUDIO OUT terminal, i.e., adjust during recording and check during playback.
6. Set the SYSTEM SELECT switch to the NTSC (MANUAL) position.
7. Supply a NTSC video signal and a 1 kHz audio signal at −20 dBs and record, then playback.
8. During recording, adjust R163 (REC LEVEL NTSC) to obtain −6 ± 1 dBs at AUDIO OUT terminal during playback, i.e., adjust during recording and check during playback.
9. Supply 1 kHz and 10 kHz audio signals at −30 dBs and record, then playback.
10. During recording, adjust R160 (REC EQ NTSC) so that during playback, 10 kHz level becomes $^{+0}_{-3}$ dB of the 1 kHz level at the AUDIO OUT terminal, i.e., adjust during recordig and check during playback.

5.7 TUNER/IF CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the TUNER/IF board.

5.7.1 Equipment required

1. Oscilloscope
2. IF sweep signal generator with suitable markers (PIF, SIF, etc.)
3. DC power supplies — for power bias (12.0 V)
   — For IF AGC bias (approx. 5 V variable)
4. Sweeper probe (sweep signal supply cable) as shown in Fig. 5-35.

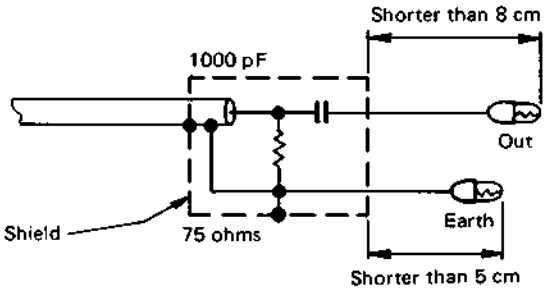

Fig. 5-35 Sweeper probe

5.7.2 IF

1. Disengage the connectors from TUNER/IF board and remove the TUNER/IF board.
2. Apply POWER bias 12.0 V DC between CONN. 23 (ALL 12 V IN) and CONN. 21 (GND).
3. Apply AGC bias 5 V DC between TP14 (IF AGC) and GND.
4. Connect a wire between CONN. 43 (TUNER CTL IN) and CONN. 42 (GND).
5. Connect the sweep generator output to test point (TP1) of TUNER and the oscilloscope to TP12 (P. DET OUT).
6. Adjust the sweep gain so that the waveform does not distort as observed with the oscilloscope.
   Adjust AGC bias for 1 $V_{p\text{-}p}$ at TP12 (P. DET OUT).
7. Adjust T3 (P. DET) so that video IF carrier 38.9 MHz marker becomes maximum level.
8. Adjust tuner module core so that 38.15 MHz marker comes to the top of the waveform.
9. Adjust T1 so that 38.15 MHz marker becomes maximum level.

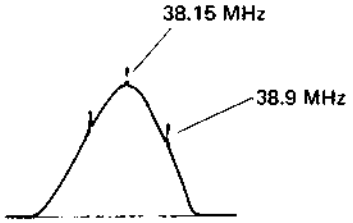

Fig. 5-36 IF adjustment

5.7.3 RF AFC

1. In the same manner as above step 5.7.2, connect the sweep generator and power supplies.
2. Connect the oscilloscope to IC1 pin 10 (AFC OUT).
3. Adjust the sweep gain so that the "S" curve indicated in Fig. 5-37 appears as observed with the oscilloscope. Adjust AGC bias so that the "S" curve does not distort.
4. Adjust T2 (AFC) so that video IF carrier (38.9 MHz) becomes 6.5 VDC as shown in Fig. 5-37.

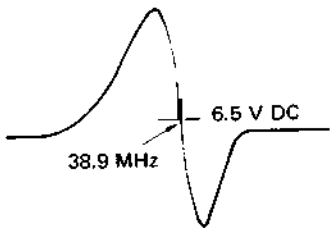

Fig. 5-37 S curve for RF AFC

5.7.4 Noise VR

Adjust the NOISE VR to correct for excess noise in the picture or streaky cross interference due to strong electric fields.

1. Receive a color broadcast and adjust R9 (NOISE) to minimize noise or streaks.
2. Check for absence of abnormality on all channels.

5.7.5 Color output level

1. Use a TV channel signal generator to supply color bar and 1 kHz audio RF signals.
2. At TP13 (VIDEO OUT), with the rated signal level taken as 100%, adjust R34 (COLOR LEVEL) so that the magenta component becomes 45%.

a : b = 1 : 0.45

Fig. 5-38 Video output level

5.7.6 Audio output level

Under the conditions as above section, adjust R4 (AUDIO LEVEL) for −14 dBs (0.44 Vp-p) at TP2 (AUDIO OUT).

5.8 TUNER/TIMER CTL CIRCUIT

Unless otherwise indicated, all test points and adjustments are located on the TUNER/TIMER CTL board. Set for the Stop (E-E) mode.

5.8.1 DAC (digital to analog converter) clock

1. Connect oscilloscope to IC202 pin 3 and connect the signal output terminal of the oscilloscope to a frequency counter.
2. Check for frequency of 1.3 MHz ±0.1 MHz and level of more than 3 Vp-p.

5.8.2 Timer CTL clock

1. Connect oscilloscope to TP201 (TIMER CTL CLOCK) and connect the signal output terminal of the oscilloscope to a frequency counter.
2. Adjust C233 (3.84 MHz ADJ) to obtain 3,840,000 Hz ± 10 Hz.

5.8.3 Tuner CTL clock

1. Connect oscilloscope to IC207 pin 1 and connect the signal out terminal of the oscilloscope to a frequency counter.
2. Confirm frequency of 400 kHz ±10 kHz and level of more than 6 Vp-p.

5.8.4 BT (band tuning voltage)

1. Connect oscilloscope to CONN. 89 (BT OUT) and set the CH PRESET switch to ON.
2. Set the Band Select switch to I (VHF channels 2 to 4) and turn the Tuning control fully counter-clockwise. Confirm DC voltage of 0.6 V.
3. Set the Band Select switch to U (UHF channels 21 to 69) and turn the Tuning control fully clockwise. Confirm DC voltage of 29 V.

5.8.5 BV, BS and BU

1. Set the CH PRESET switch to ON and the Band Select switch sequentially to positions I, III and U.
2. Use a digital voltmeter and measure the voltages at tuner BV, BS and BU terminals. Check for values indicated in Table 5-2.

Voltage / Band	BV	BS	BU
I (V_L)	More than 11.5 V	More than 30 V	Less than 0.8 V
III (V_H)	More than 11.5 V	Less than 0.8 V	Less than 0.8 V
U	Less than 0.8 V	Less than 0.8 V	More than 11.5 V

Table 5-2 BV, BS and BU voltages

5.8.6 Display clock

1. Connect oscilloscope to IC401 pin 1 of the DISPLAY board and connect the signal out terminal of the oscilloscope to a frequency counter.
2. Confirm oscillation frequency of 400 kHz ±10 kHz and level of more than 6.0 Vp-p.

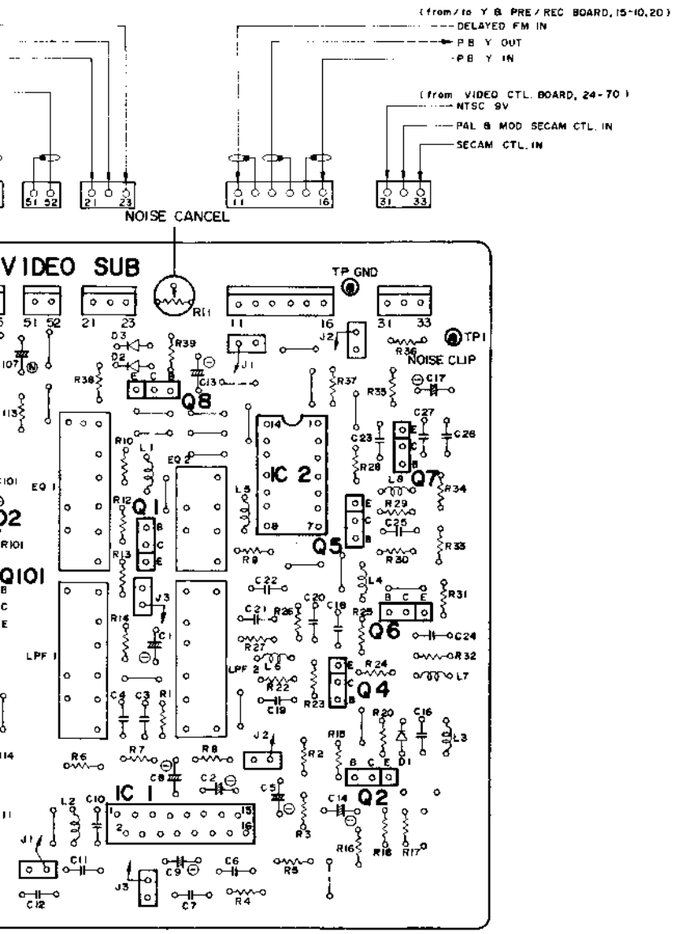
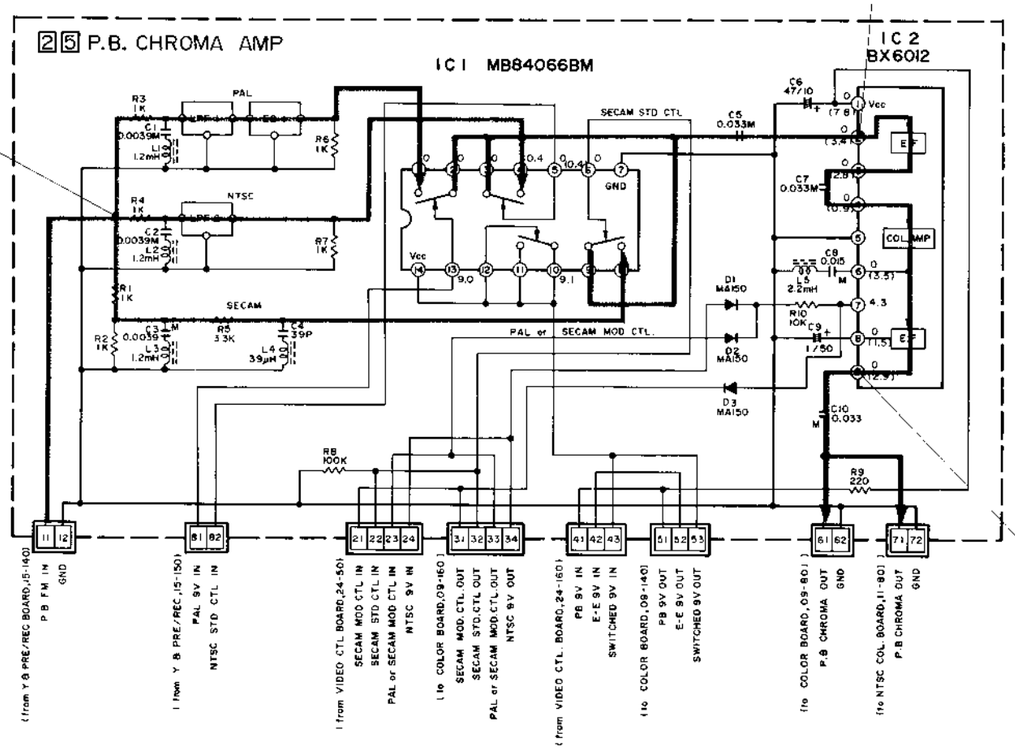
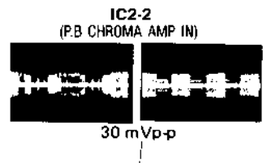
6-12 VIDEO SUB, PB CHROMA AMP (Y & PRE/REC)

6 . 11 PB CHROMA AMP CIRCUIT

6 . 11 . 1 Schematic diagram



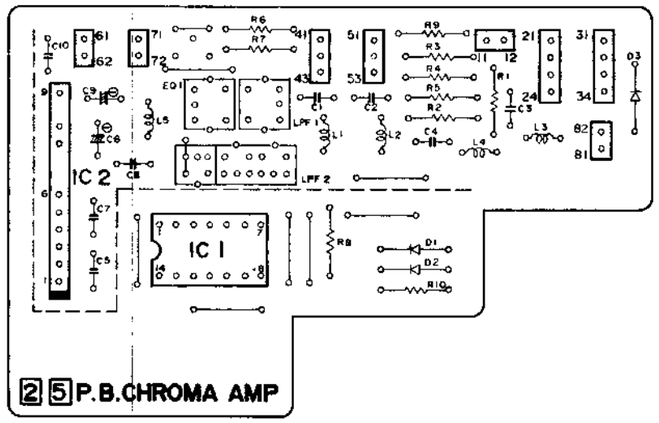




NOTE:
1. Voltage are DC-measured with a digital voltmeter during PAL playback mode.

NOTE:
Waveform is PAL playback mode.

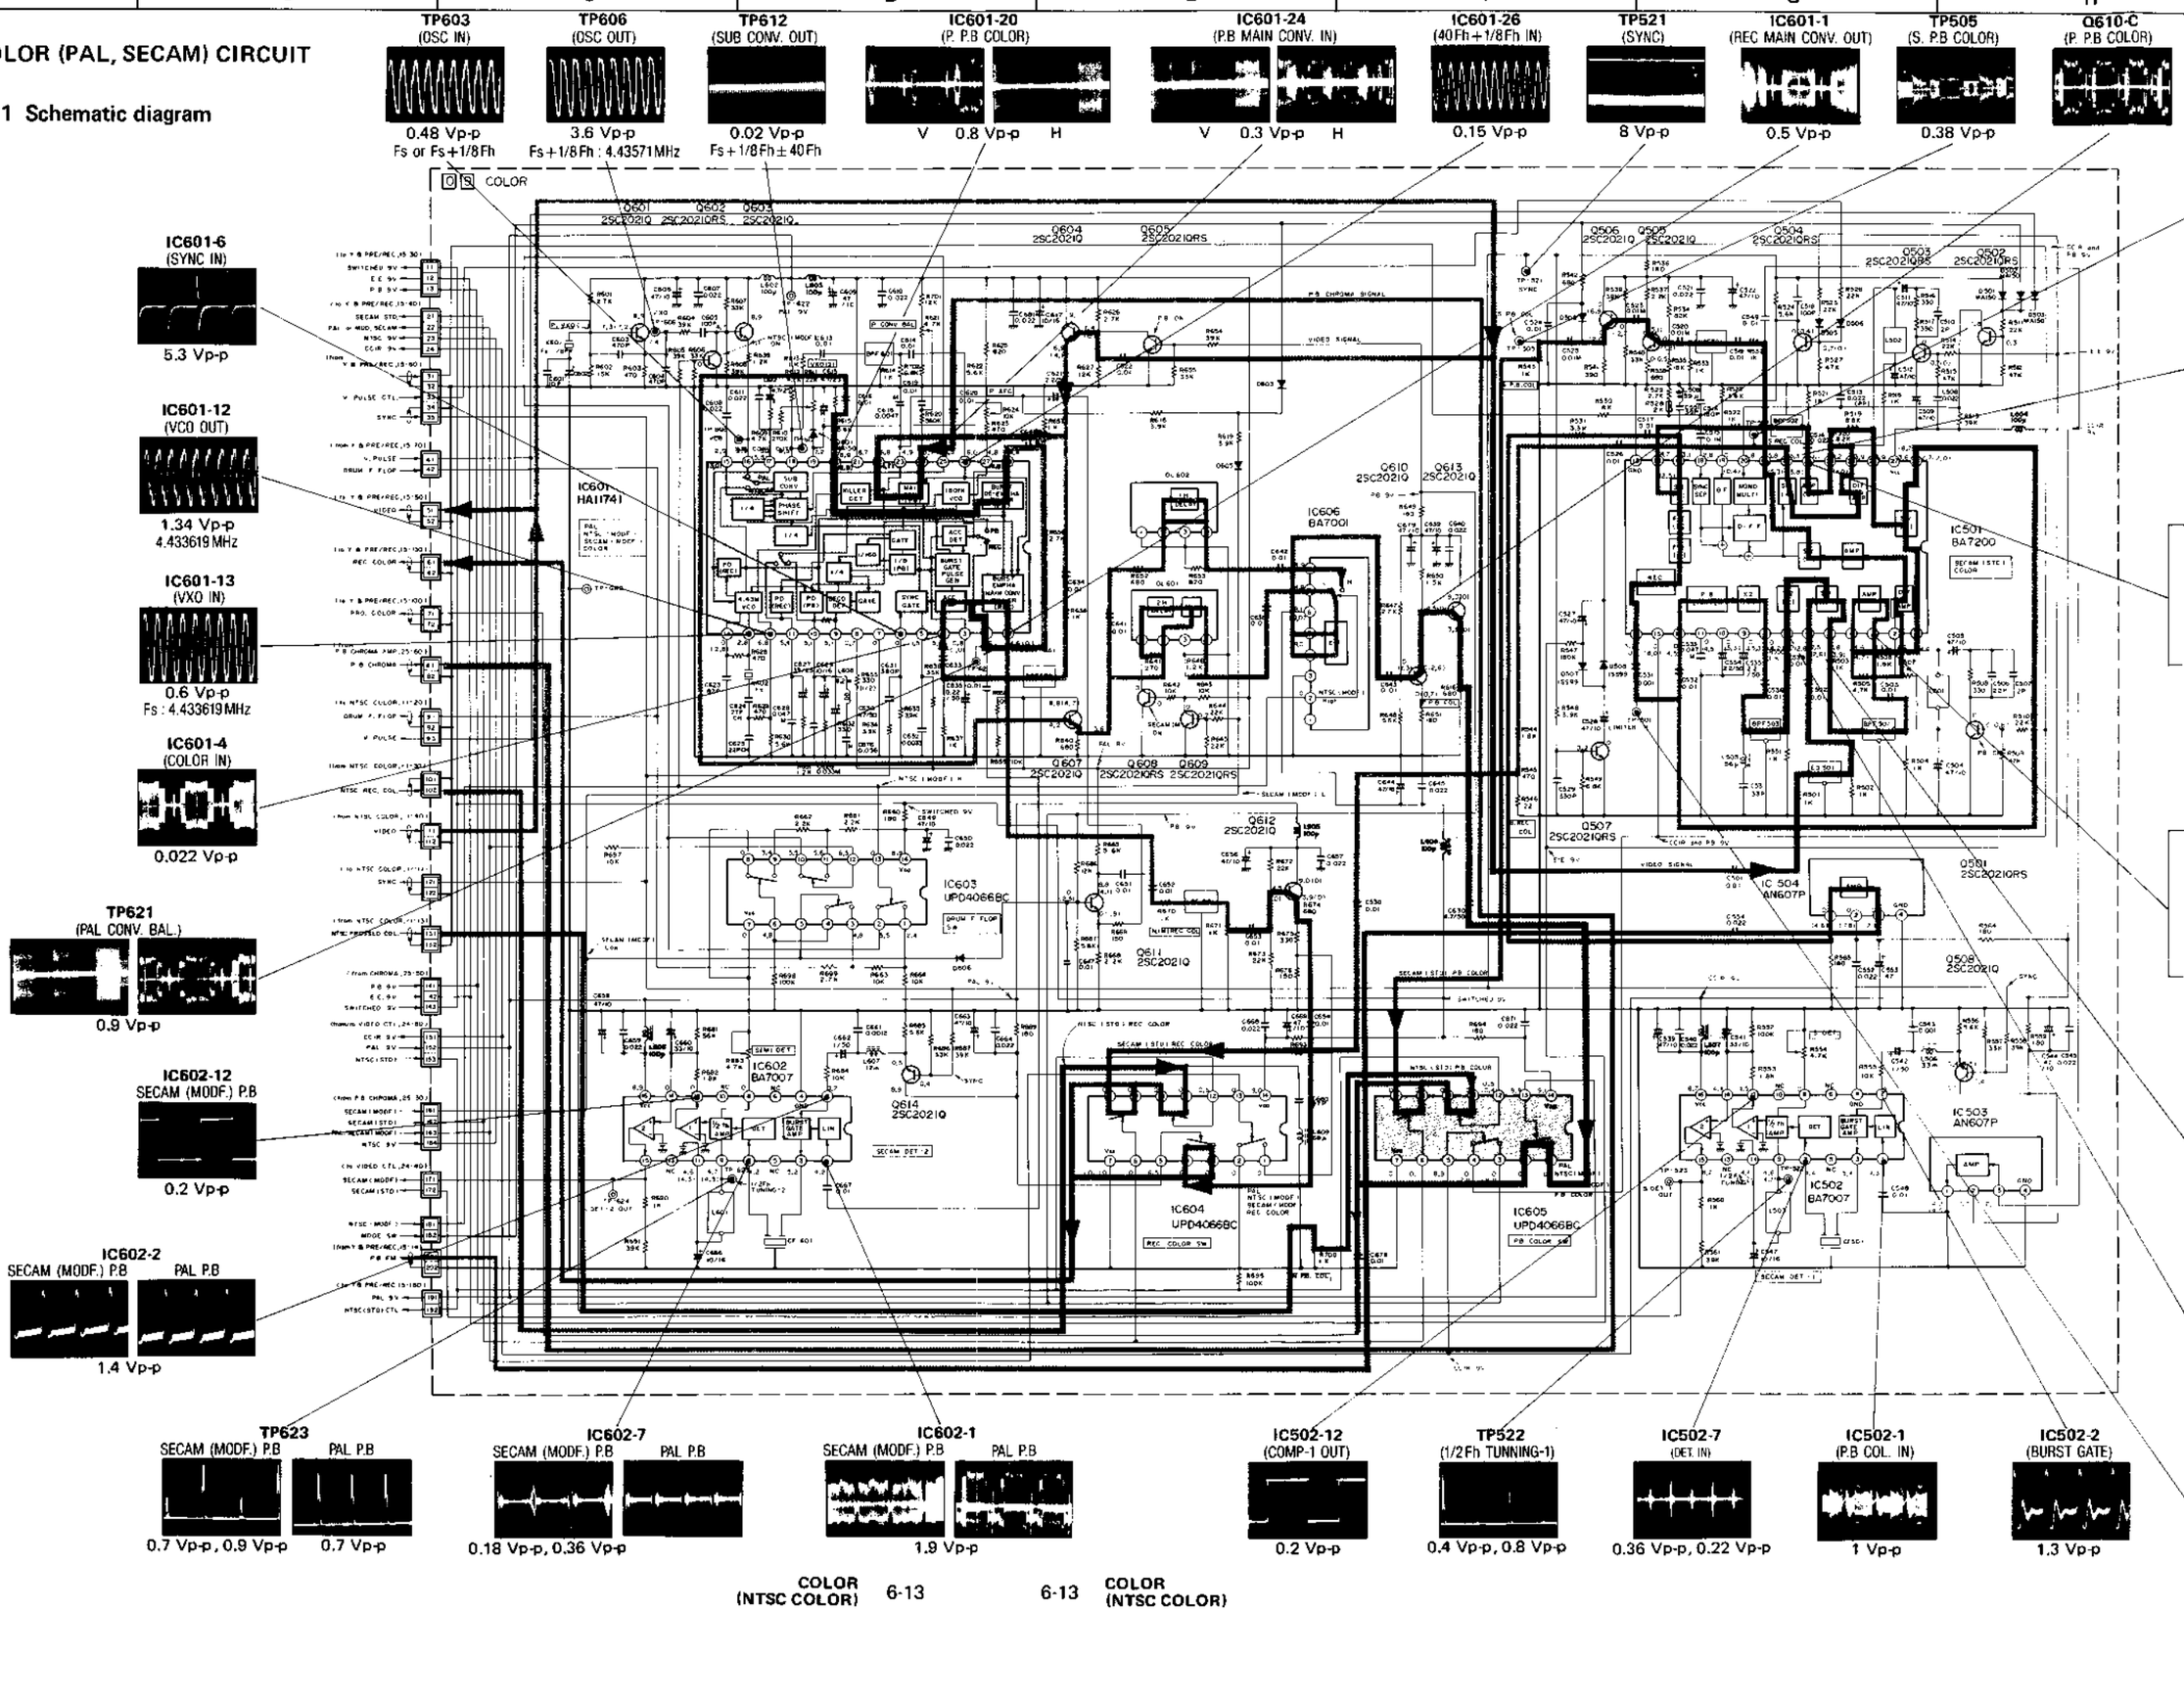
6 . 11 . 2 Circuit board



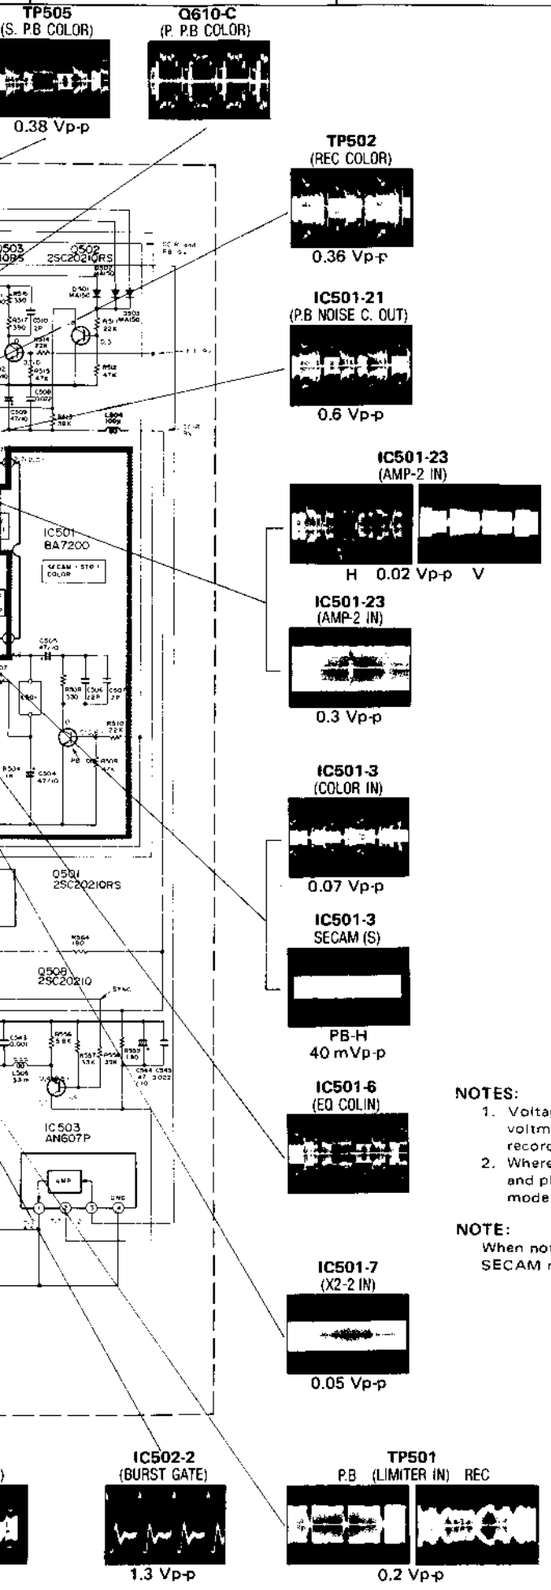
6-12 VIDEO SUB, PB CHROMA AMP (Y & PRE/REC)

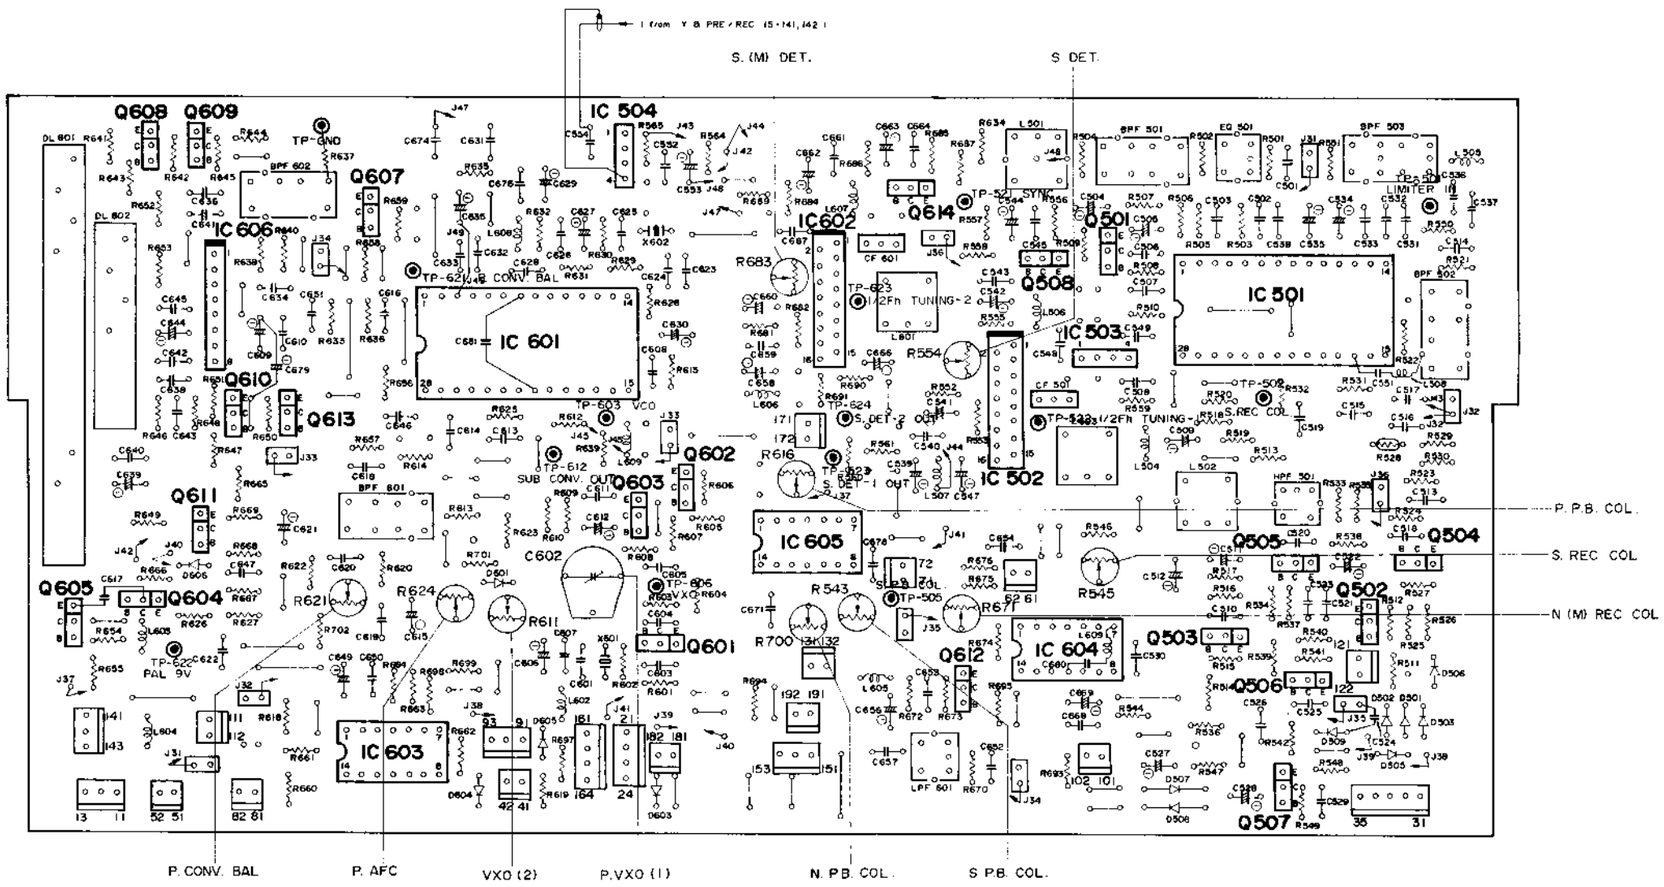
6 . 12 COLOR (PAL, SECAM) CIRCUIT

6 . 12 . 1 Schematic diagram



6 . 12 . 2 Circuit board





NOTES:

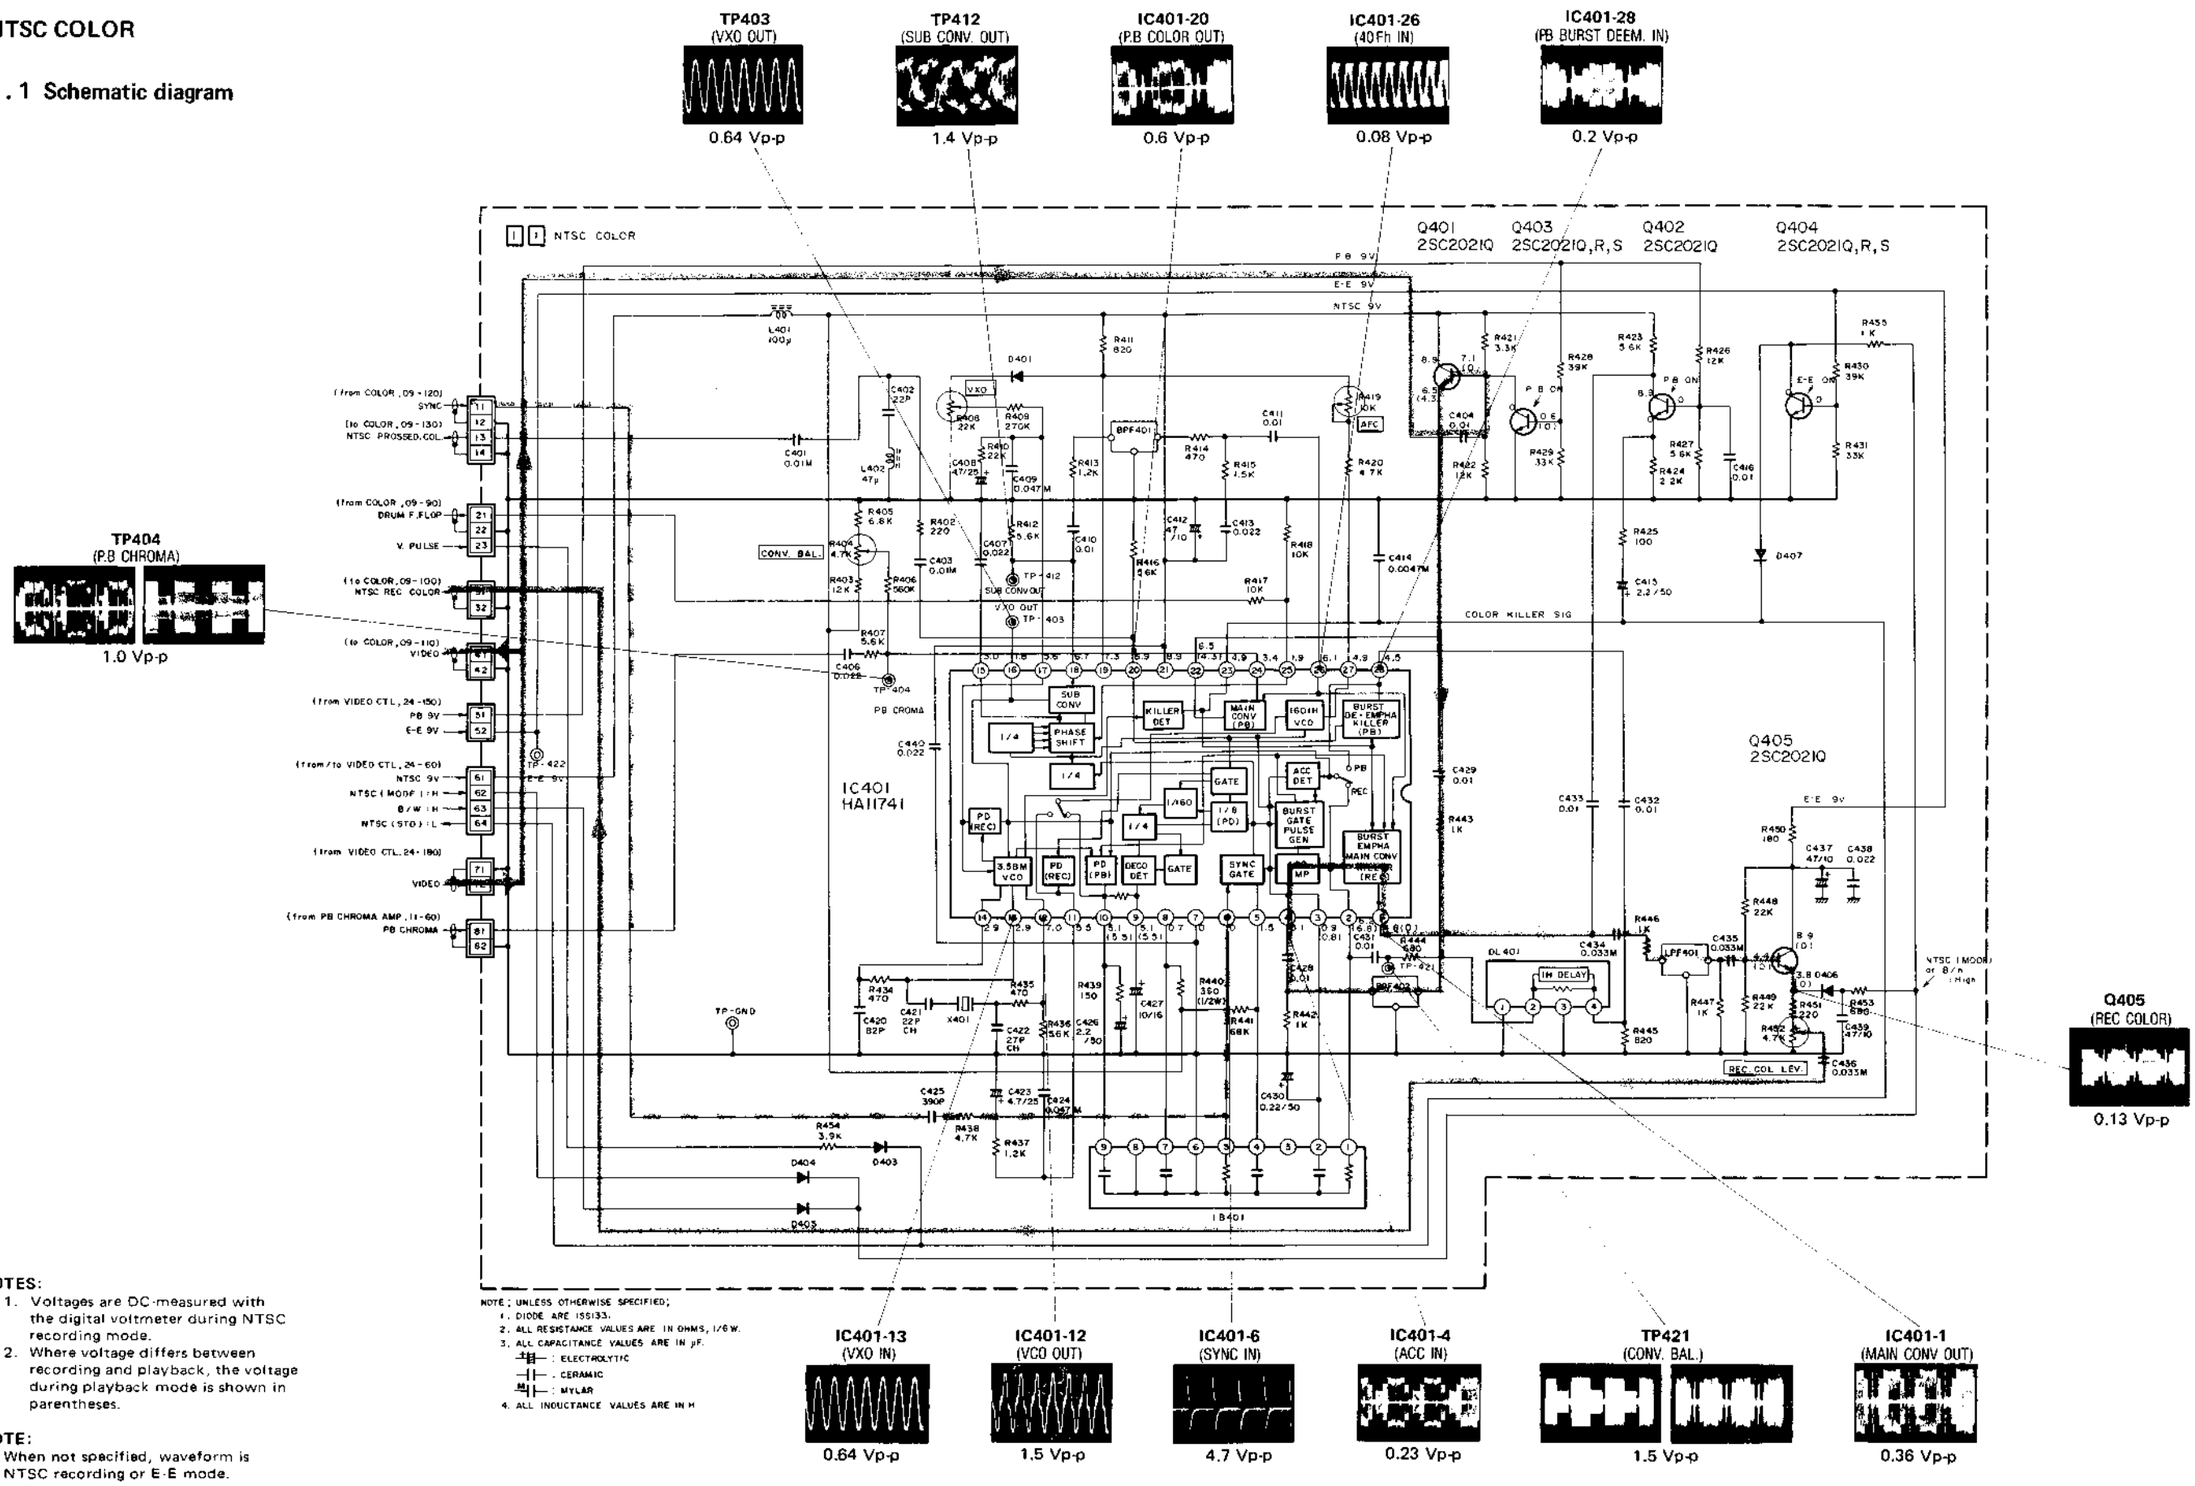
1. Voltages are DC measured with a digital voltmeter during PAL or SECAM recording mode.
2. Where voltage differs between recording and playback, the voltage during playback mode is shown in parentheses.

NOTE:

When not specified, waveform is PAL or SECAM recording mode or E-E mode.

6 . 13 NTSC COLOR

6 . 13 . 1 Schematic diagram



NOTES:

1. Voltages are DC-measured with the digital voltmeter during NTSC recording mode.
2. Where voltage differs between recording and playback, the voltage during playback mode is shown in parentheses.

NOTE:

When not specified, waveform is NTSC recording or E-E mode.

NOTE ; UNLESS OTHERWISE SPECIFIED;
1. DIODE ARE 1SS133.
2. ALL RESISTANCE VALUES ARE IN OHMS, 1/6W.
3. ALL CAPACITANCE VALUES ARE IN μF.
   ⊣‖⊢ : ELECTROLYTIC
   ⊣|⊢ : CERAMIC
   ⊣M⊢ : MYLAR
4. ALL INDUCTANCE VALUES ARE IN H

6 . 13 . 2 Circuit board

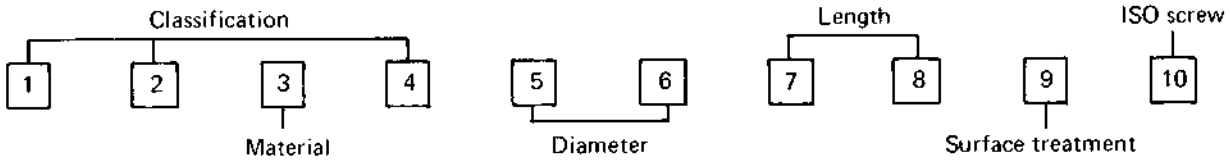
SECTION 7
EXPLODED VIEWS AND PARTS LIST

SAFETY PRECAUTION

Parts identified by the ⚠ symbol are critical for safety.
Replace only with specified part numbers.

7.1 STANDARD PART NUMBER CODING

7.1.1 Screw coding



Classification (first digit)

Symbol Letter	Name
S	Normal screw
N	Assembly screw
L	"
D	"
M	Wood screw
F	Feather screw
T	Set screw
Y	"
B	Bolt
N	Nut
W	Washer
R	E-ring
E	Eyelet
P	Spring
G	Washer head screw

Material (third digit)

Symbol Letter	Material
S	Steel
E	Stainless steel
C	Cast iron
U	Bronze
B	Brass
P	Phosphor bronze
N	German silver
Y	Brass
A	Aluminum
Z	Zinc alloy
K	Polycarbonate

Surface Treatment (ninth digit)

Symbol Letter	Surface Treatment
Z	Galvanization, dichromic acid treatment (MFZn2-C)
N	Nickel plating (MFNi2, MFNil)
R	Chrome plating (MBCr2, MBCr1)
G	Silver plating (SP4)
W	Nichrome platings
P	Phosphite treatment
B	Bronze plating

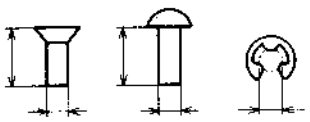
Shape of Screw Head (second digit)

Symbol Letter		Shape of Screw Head
P		Pan head
S		Flat countersunk head
H		Oval countersunk head
D		Binding head
R		Round head
B		Round head
T		Truss head

Type of Screw (fourth digit)

Symbol Letter	Type of Screw
P	Cross-Recessed head screw
A	Tapping screw
B	Special tapping screw
T	Special tapping screw
E	Special tapping screw
F	Special tapping screw

Diameter and Length of Screw (fifth – eighth digit)



– Example –

S P B P 3 0 0 6 Z S

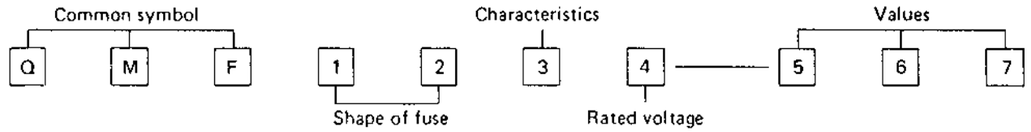
(Diameter x 10) (Length)

Diameter : 3 mm

Length : 6 mm

Symbol letter	Surface treatment
M	Black coloring after galvanization
A	Red coloring after galvanization
C	Blue coloring after galvanization
T	Green coloring after galvanization
V	Violet coloring after galvanization
F	Iron with black coloring

7.1.2 Fuse coding



Shape of Fuse (first and second digit)

Symbol No.	Shape	Remarks
51		ϕ 5.2 x 20
60		ϕ 6.4 x 30
61		ϕ 6.35 x 31.8
63		With 60 Lead Wire
66		With 61 Lead Wire

Rated Voltage (fourth digit)

Symbol No.	Rated Voltage	
1	AC 125 V	
2	AC 250 V	
3	100 mA ~ 1 A	AC 250 V
	1.25 A ~ 6.3 A	AC125 V

Values (fifh-seventh digit)

R10	.....	100 mA
R125	.....	125 mA
1R0	.....	1.0 A
1R2	.....	1.2 A
1R25	.....	1.25 A
100	.....	10 A

Characteristics (third digit)

Symbol No.	Fusing Current	Fusing Time	Remarks
S	160%	Within 1 hr.	Anti-rush Type
	200%	" 2 min.	
	700% – 2000%	" 0.01 sec.	
R	160%	" 1 hr.	Regular Fusible Type
	200%	" 2 min.	
M	135%	" 1 hr.	Regular Fusible Type (for UL)
	200%	" 2 min.	
U	135%	" 1 hr.	Anti-rush Type (for UL)
	200%	" 2 min.	
	800% – 2000%	" 0.01 sec.	
A	210%	" 2 min.	Anti-rush Type (for Europe)
	275%	0.5 – 10 sec.	
	400%	0.15 – 2 sec.	
	1000%	0.02 – 0.3 sec.	
B	210%	Within 30 min.	Regular Fusible Type (for SEMKO, Europe)
	275%	0.05 – 2 sec.	
	400%	0.01 – 0.3 sec.	
C	135%	Within 1 hr.	Anti-rush Type (for UL, Japan)
	200%	" 2 min.

SECTION 8
ELECTRICAL PARTS LIST

SAFETY PRECAUTION

Parts identified by the ⚠ symbol are critical for safety. Replace only with specified part numbers.

ABBREVIATIONS IN THIS LIST ARE AS FOLLOWS:

RESISTORS – All resistance values are in ohms (Ω).

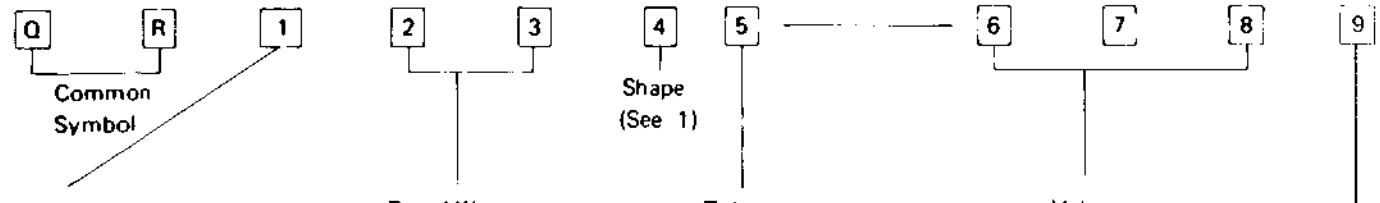
K	: 1 000
M	: 1 000 000
CR	: Carbon Resistor
Comp. R	: Composition Resistor
WR	: Wire Wound Resistor
OMR	: Oxide Metal Film Resistor
VR	: Variable Resistor (Potentiometer)
MFR	: Metal Film Resistor
FR	: Fusible Resistor

CAPACITORS – All capacitance values are in μF, unless otherwise indicated.

P	: μμF
C Cap	: Ceramic Capacitor
E Cap	: Electrolytic Capacitor (L. L : Low Leakage)
FM Cap	: Film Mica Capacitor
MM Cap	: Metalized Mylar Capacitor
MP Cap	: Metalized Paper Capacitor
MY Cap	: Mylar Capacitor
NP Cap	: Non-polar Capacitor
PC Cap	: Polycarbonate Capacitor
PP Cap	: Poly Pro Capacitor
PS Cap	: Polystyrol Capacitor
T Cap	: Tantalum Capacitor
TR Cap	: Trimmer Capacitor

8.1 STANDARD PART NUMBER CODING

8.1.1 Fixed Resistor Coding



Type of resistor

C	Composition Resistor
D	Carbon Resistor
F	Unflammable Resistor
G	Oxide Metal Film Resistor
M	Metal Plate Resistor
X	Metal Film Resistor
W	Wire Wound Resistor
Y	Wire Wound Resistor
V	Metal Film Resistor, High Stability
Z	Special Resistor

Rated Wattage

Symbol	Rated wattage
16	1/6 (W)
18	1/8 "
14	1/4 "
12	1/2 "
01	1 "
02	2 "
03	3 "
04	4 "
05	5 "
06	6 "
07	7 "
75	7.5 "
08	8 "
10	10 "
15	15 "
20	20 "
30	30 "

Tolerance

Symbol	Tolerance
F	±1 %
G	±2 %
J	±5 %
K	±10 %
M	±20 %

Values

– Example –		
R47		0.47 Ω
4R7		4.7 Ω
470	47×10^0	47 Ω
471	47×10^1	470 Ω
472	47×10^2	4.7 KΩ
473	47×10^3	47 KΩ
474	47×10^4	470 KΩ
475	47×10^5	4.7 MΩ
10R2		10.2 Ω
1430	143×10^0	143 Ω
1581	158×10^1	1.58 KΩ

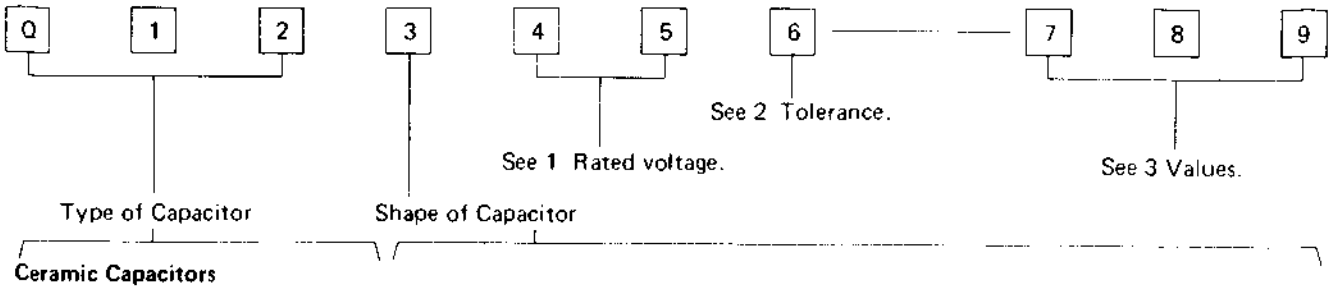
Size

Symbol	Size
A	Small Size
S	Small Size

1) **Shape of resistor** (■ : Flame retardant resistor)

Sort	C	D	G	F	M	W	X	Y	V
1									
2									
3									
4									
5						L type			
6						Resin Covered			
7						Enameled			
8									
9									

8.1.2 Fixed Capacitor Coding



Ceramic Capacitors

Symbol	Type of Capacitor	Disk Lead	Kink Lead			
QCC	Ceramic			4	5	
QCF	"	1	3			
QCS	"	1	3			
QCX	"			1	3	
QCY	"	1,4	3			
QCT	Temperature compensation					
QCZ	Special					

Electrolytic Capacitors

Symbol	Type of Capacitor	Tubular	Mono-direction	Anti-stress	Forming	Snap-in
QEA	Characteristic A	2	4			
QEB	Low leakage		4	5	6	
QED	Characteristic D	2	4			
QEE	Tantalum		4	5		
QEE	" (small type)		8			
QEL	Characteristic L					7
QEN	Non-polar	2	4	5	6	
QEW	Characterisitc W	2	4	5	6	7
QET	Characteristic W (small type)	2	4	5	6	
QEK	Characteristic W (subminiature type)		4	5		
QEZ	Special					

Paper Film Capacitors

Symbol	Type of Capacitor	Tubular	Normal		Flame retardant	
			Mono-direction	Kink Lead	Mono-direction	Kink Lead
QFF	Film mica		4			
QFH	Metalized mylar	2	4	3	5	6
QFM	Mylar	2	4	3, 7	5	6
QFN	" (small type)		4			
QFP	Polypropylene		4	3		
QFS	Polystyrole	2	4	3		
QFZ	Special					

1) Rated voltage (V)

First letter \ 2nd letter	A	B	C	D	E	F	G	H	J	K	V	W	X
0						3.15			6.3				
1	10		16	20	25		40	50	63		35		
2	100	125	160	200	250	315	400	500	630		350	450	600
3	1000	1250		2000				5000					

2) Tolerance

Symbol	F	G	J	K	M	N	Z	P	A	H	R
(%)	±1	±2	±5	±10	±20	±30	+80 −20	+100 - 0	+100 - 10	+50 -10	+30 -10

3) Values

– Example – Values are in picofarads.

101 ..... 10×10^1 ..... 100 pF

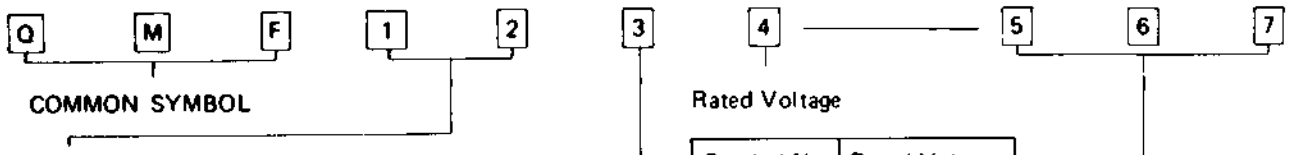
102 ..... 10×10^2 ..... 1,000 pF

103 ..... 10×10^3 ..... 10,000 pF = 0.01 μF

104 ..... 10×10^4 ..... 100,000 pF = 0.1 μF

5R0 ..... 5.0 ..... 5 pF

8.1.3 Fuse Coding



Shape of Fuse

Symbol No.	Shape	Remarks
51		φ5.2 x 20
60		φ6.4 x 30
61		φ6.35 x 31.8
63		With 60 Lead Wire
66		With 61 Lead Wire

Rated Voltage

Symbol No.	Rated Voltage
1	AC 125 V
2	AC 250 V

Values

R10	0.1 A
R125	0.125 A
1R0	1.0 A
1R2	1.2 A
1R25	1.25 A
100	10 A

Characteristics

Symbol No.	Fusing current	Fusing time	Remarks
S	160%	Within 1 hr.	Anti-rush Type
	200%	" 2 min.	
	700%–2000%	" 0.01 sec.	
R	160%	" 1 hr.	Regular Fusible Type
	200%	" 2 min.	
M	135%	" 1 hr.	Regular Fusible Type (for UL)
	200%	" 2 min.	
U	135%	" 1 hr.	Anti-rush Type (for UL)
	200%	" 2 min.	
	800%–2000%	" 0.01 sec.	
A	210%	" 2 min.	Anti-rush Type (for Europe)
	275%	0.5 – 10 sec.	
	400%	0.15 – 2 sec.	
	1000%	0.02 – 0.3 sec.	
B	210%	Within 30 min.	Regular Fusible Type (for SEMKO, Europe)
	275%	0.05 – 2 sec.	
	400%	0.01 – 0.3 sec.	

8.2 ELECTRICAL PARTS LIST BY ASSEMBLIES

8.2.1 Start Sensor Board [0][1]

Symbol No.	Part No.	Part Name	Recommended Part/ Description
	PU51579	Circuit Board	
PT01	PN202S	Photo Transistor	

8.2.2 End Sensor Board [0][2]
