1. GENERAL

Nakamichi 620 control functions are shown below.

1. Peak Power Indicator (L ch)
2. Peak Power Indicator (R ch)
3. AC Power Indicator
4. Power Switch
5. Power Indicator Threshold Selector Switch (High)
6. Power Indicator Threshold Selector Switch (Low)
7. Fuse
8. Voltage Selector
9. Output Terminals
10. Input Jacks

Fig. 1.1

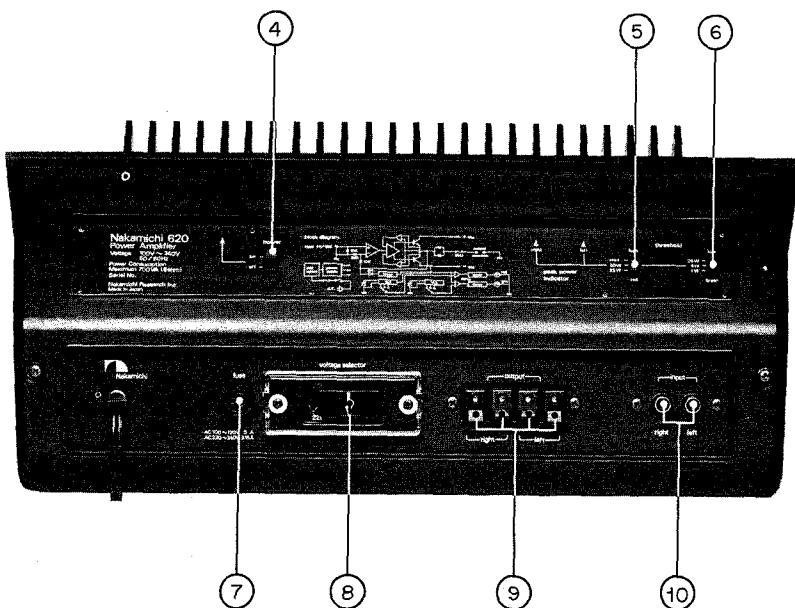

Fig. 1.2

CAUTIONS

The Nakamichi 620 incorporates large capacitances. It is very dangerous to access the capacitor for a duration of about 3 minutes after the power switch has been turned off because of incomplete discharging. Use extreme care when accessing the capacitor for repair purposes.

Never short the capacitor terminals with a screwdriver or a similar tool after the power switch is turned off, with an attempt to discharging the capacitor. (Shorting the terminal in such a way can melt the shorted point leading to a hole, and will give adverse effects on the capacitor itself.)

The recommended way to discharge the capacitor as quickly as possible is to turn off the power supply with sound emitting through the loudspeaker or to discharge the capacitor with resistances of $100\Omega - 300\Omega$, approx. 20W.

Voltage Selector

Change over to 100V, 117V, 220V or 240V.

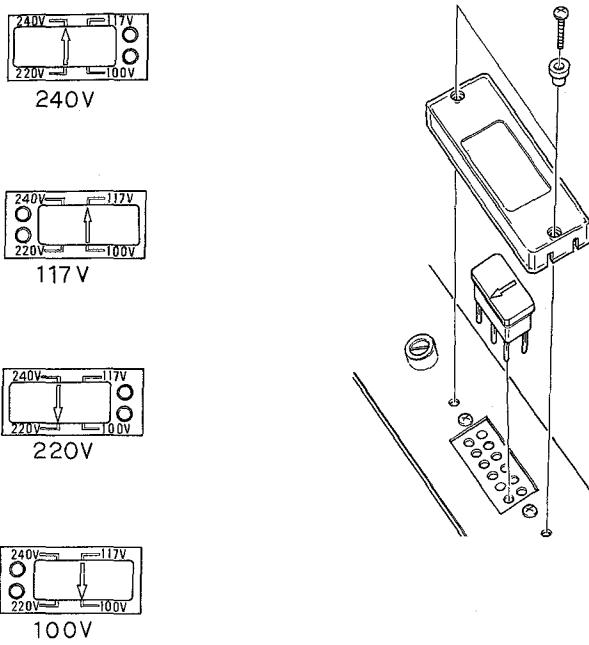

Fig. 1.3

2. PRINCIPLE OF OPERATION**2.1. Power Supply**

Refer to Fig. 2.1.

The power transformer used in the 620 is of a toroidal type. Generally, a toroidal transformer is attacked by large rush current when the power switch is turned on. For the 620, such rush current is reduced by supplying input voltage to the primary of the transformer via a resistor (6.8Ω , 10 watts) only during the time of approx. 20 msec

when the power switch is turned on, and then by shorting the resistance at a relay contact and supplying the input voltage directly to the transformer primary.

A 130°C thermal fuse is contained within the transformer and protects it from unusual heating.

If the fuse is blown, it is necessary to replace the transformer itself.

2.2. Power Block Pre-stage

Refer to Fig. 2.2.

As all the output stage consists of emitter-followers, the voltage gain is 1. Therefore, the gain required for power amplifier and NFB is obtained at the pre-stage. Generally, an increase in the number of transistor stages of an amplifier circuit increases distortion and phase shift. In large current amplification as seen with a power amplifier, a certain extent of distortion cannot be avoided and should be limited through use of NFB. However, excessive NFB is likely to cause unstable amplification as a result of phase shift in the amplifier or differences in loudspeaker impedance. This is one of the drawbacks inherent to an NFB amplifier.

The power amplifier used in the 620 employs 8 transistors, of which only two serve for voltage amplification and the remaining six are used to provide the former two with the best operating conditions. A gain of approx. 100dB is obtained through these two transistors to perform power amplification and NFB. The amplifier of this configuration assures stable NFB with low noise and low distortion and with little phase shift.

Q001 and Q007 are for voltage amplification; Q002 and Q003 form a current mirror circuit (the same current at both collectors); Q005 and Q008 provide a constant-current source; Q006 is for impedance conversion (emitter-follower); Q004 and Q001 make up a differential amplifier circuit. Thus, stable NFB is applied through a circuitry using these transistors.

C005 determines the high-band characteristic of the voltage amplifier to prevent NFB from becoming unstable because of unbalanced performance. R016 is a resistor for NFB.

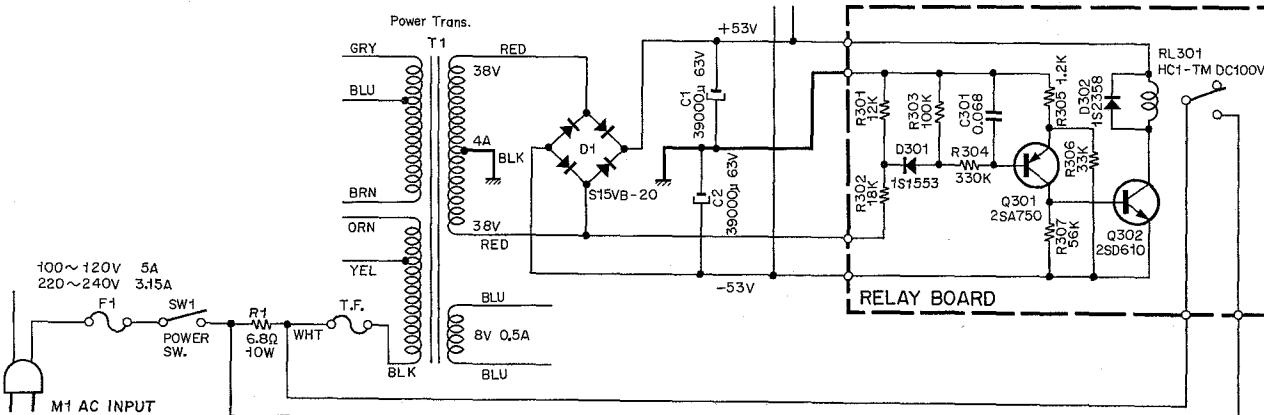

Fig. 2.1

2.3. Power Block Output Stage

In the Nakamichi 620, for making a bias voltage, varistor used in the conventional design of amplifier is replaced with transistor base-emitter so that the 620 design improves bias stability (against temperature or current changes) with lower distortion.

Especially for a class B push-pull amplifier, distortion cannot be reduced unless the positive and negative signal amplifiers are well balanced. The amplifier in the 620, however, is best balanced thanks to the vertically and horizontally symmetric configuration as shown in Fig. 2.3. This circuit allows distortion of only 0.1% at 1KHz 100 watts output even without NFB. This degree of distortion is low enough to make the amplifier used as a high-fidelity unit even if it is given no NFB.

Fig. 2.4 shows that a change in current flowing across the diode varies the terminal voltage and that E_b changes with signal current. These changes result in the generation of distortion. It is a matter of course that signal current flowing across the diode will produce distortion. See Fig. 2.3. Transistors Q009, Q011, Q010 and Q012 that generate bias voltage form an emitter-follower circuit of class A operation. Thus this circuit does not induce distorted signals.

Unless corrected perfectly against temperatures, the bias voltage of power amplifiers in the class B amplifier will increase distortion at low temperature or become unstable at high temperature. It may safely be said that temperature compensation of a transistor can be more properly and effectively carried out by the transistor of the same structure than a diode.

For an ordinary class B amplifier, crossover distortion is reduced by increasing idling current thus overlapping the operating ranges of the positive and negative transistors. The overlap portion acts as a class A amplifier. Generally, the degree of amplification decreases where a change takes place from class A to B and no linear curve is obtained as shown in Fig. 2.5 (A). However, if the circuit shown in Fig. 2.3 is current-driven, a linear curve can be obtained at the point of change from class A to B as shown in Fig. 2.5 (B).

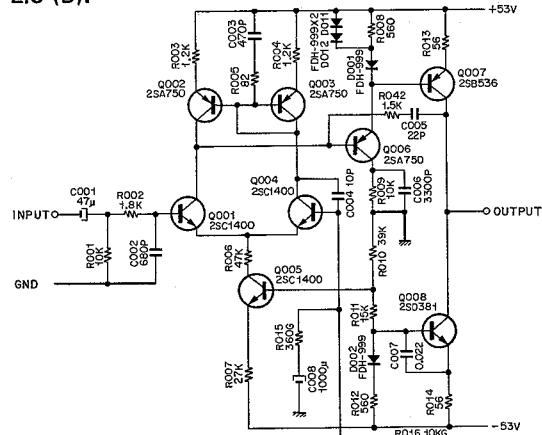

Fig. 2.2

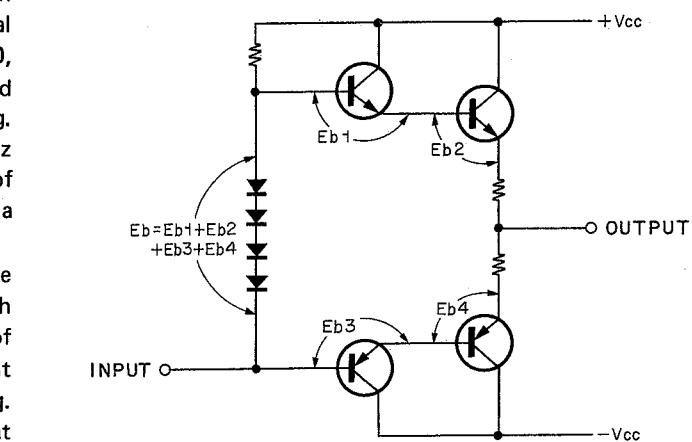

Fig. 2.4

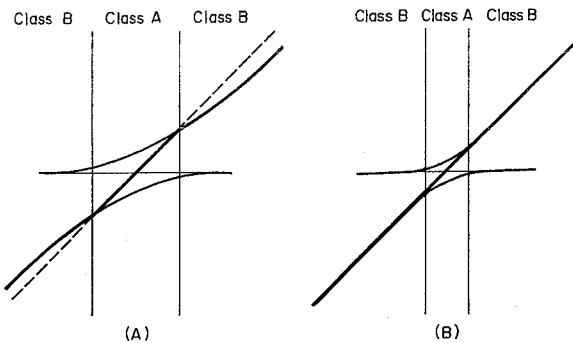

Fig. 2.5

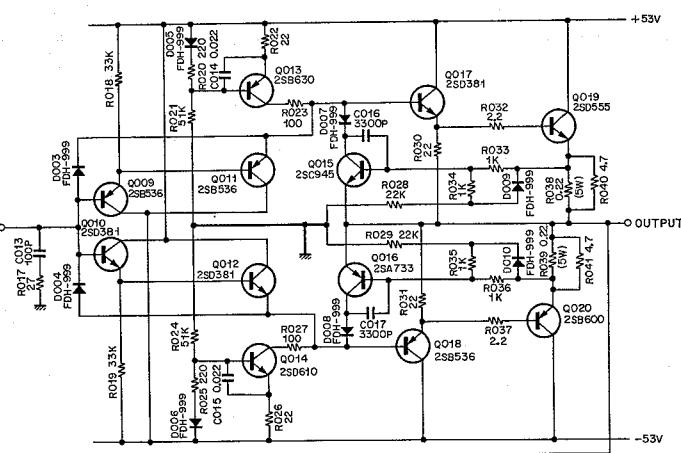

Fig. 2.3

Fig. 2.6 illustrates a simplified version of the circuit shown in Fig. 2.3.

Since the direct-coupled two-stage emitter-followers can be regarded to be one emitter-follower having greater current amplification, the Q009–Q011, Q010–Q012, Q017–Q019, and Q018–Q020 will be designated respectively to be Q1, Q2, Q3 and Q4 as shown in Fig. 2.6.

When i_d is applied with the input used as current-source, i_1 and i_2 are given as follows because of the Q1 and Q2 input impedances:

$$\text{Input impedance of Q1 } \beta_1 (\beta_3 r_1 + r_3)$$

$$\text{Input impedance of Q2 } \beta_2 (\beta_4 r_2 + r_4)$$

Therefore;

$$i_1 = \frac{\beta_2 (\beta_4 r_2 + r_4)}{\beta_1 (\beta_3 r_1 + r_3) + \beta_2 (\beta_4 r_2 + r_4)} i_d$$

$$i_2 = \frac{\beta_1 (\beta_3 r_1 + r_3)}{\beta_1 (\beta_3 r_1 + r_3) + \beta_2 (\beta_4 r_2 + r_4)} i_d$$

$$i_0 = i_3 + i_4 = \beta_1 \beta_3 i_1 + \beta_2 \beta_4 i_2$$

$$= \frac{\beta_1 \beta_2 \beta_3 (\beta_4 r_2 + r_4) + \beta_1 \beta_2 \beta_4 (\beta_3 r_1 + r_3)}{\beta_1 (\beta_3 r_1 + r_3) + \beta_2 (\beta_4 r_2 + r_4)} i_d$$

$$= \frac{\beta_1 \beta_2 \beta_3 \beta_4 \left\{ (r_2 + r_4/\beta_4) + (r_1 + r_3/\beta_3) \right\}}{\beta_1 \beta_3 (r_1 + r_3/\beta_3) + \beta_2 \beta_4 (r_2 + r_4/\beta_4)} i_d$$

If β of the Q₁–Q₃ pair is equal to that of the Q₂–Q₄ pair, then $\beta_1 \beta_3 = \beta_2 \beta_4$ (assumed as β_0).

The following equation will be obtained:

$$i_0 = \frac{\beta_0^2 \left\{ (r_2 + r_4/\beta_4) + (r_1 + r_3/\beta_3) \right\}}{\beta_0 \left\{ (r_1 + r_3/\beta_3) + (r_2 + r_4/\beta_4) \right\}} i_d$$

$$= \beta_0 i_d$$

As a result, the same gain is obtained over the entire range as shown in Fig. 2.7.

Thus, the rate of current amplification in the idling current range (Class A) is quite the same as that in the class B amplifier. It must be noted, however, that the idling current is not included in the conditions for making the equation valid. In other words, a change in idling current will neither change the linearity of curves nor produce distortion.

Q013 and Q014 form a constant-current source; D005 and D006 are for temperature compensation; D003 and D004 prevent reverse-biased voltage from being applied in abnormal state; Q015 and Q016 form a current limiter that prevents overloading on the power transistor.

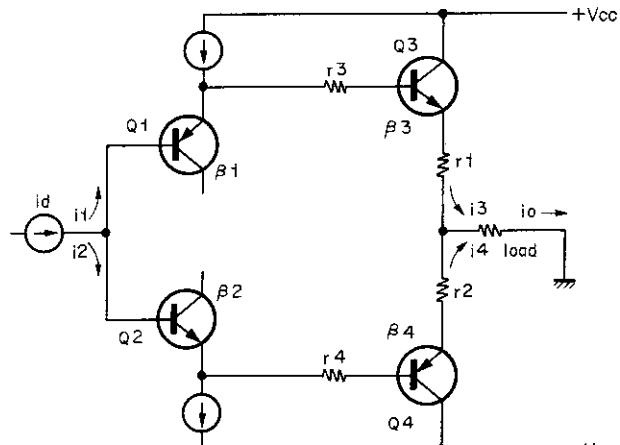

Fig. 2.6

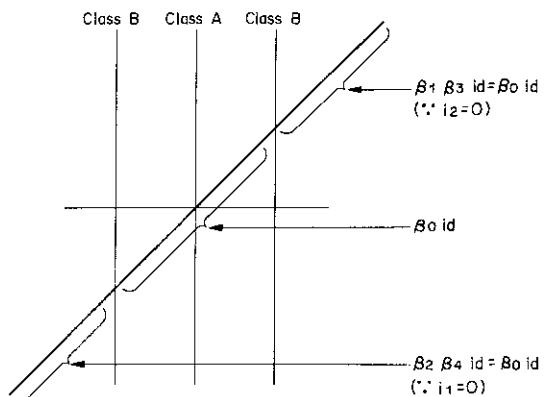

Fig. 2.7

2.4. Peak Power Indicator

Fig. 2.8 and Fig. 2.9 show, respectively, the circuit diagram and time chart of the peak power indicator. This circuit switches the peak power indicator of R-channel or L-channel to red or green depending upon the output power level.

The LOW and HIGH power indicator threshold selectors located on the rear panel of the 620 select 1/5/25 watts and 25/50/Max. watts power levels, respectively. The green lamp glows for output power levels of 1,5,25 watts (LOW) or more, while the red lamp glows for output power levels of 25, 50 or Max. watts (HIGH). (Ref. 8Ω load. If a 16Ω loudspeaker is to be used, divide the indicated power levels by two.)

The green lamp remains off while the red lamp is on. If both switches are set for 25 watts, the peak power indicator lamps will glow red only at that power point. The peak power indicating lamps are extremely fast in responding to transmit signals. A 0.1 millisecond power pulse will cause the peak indicator to light and stay "on" for 0.3 second.

AMP1 is a full-wave rectifier for input waveforms (namely output waveforms to the loudspeaker).

AMP2 is a peak detector.

Capacitor C151 and resistor R156 determine the time constant for holding the voltage of which peak has been detected.

AMP3 and AMP4 form a comparator that compares the output voltage of AMP2 with reference voltage (corresponding to power level 1, 5, 25 or Max. watts).

AMP3 and AMP4 are operational amp. ICs with open collector output. Output of these amplifiers is -5V if the AMP2 output voltage is lower than the reference voltage. In this state, transistors Q151 and Q153 are cut off and the lamps are off.

In AMP3, if the AMP2 output voltage exceeds the reference, the AMP3 output is opened and base current flows into Q151 via resistor R164. As a result, Q151 is on and the indicating lamp glows green.

In AMP4, if the AMP2 output voltage exceeds the reference, the AMP4 output is opened and base current flows into Q153 via resistor R163. As a result, Q153 is on and the indicating lamp glows red.

Then, the collector of Q153 is dropped to -5V and no current flows to Q151 via R164. Thus Q151 is cut off and the green lamp goes out.

AMP4 has hysteresis in its input/output characteristic.

Q151, Q152, and Q153, Q154 make up a sort of monostable multivibrator.

When Q151 is on and Q152 is therefore on, a positive differential pulse is applied to the Q151 base via capacitor C152. Thus Q151 is held "on" for a certain time.

Q153 and Q154 operate in the same manner as above. R157 (R165) is a resistor causing a lamp to be pre-biased.

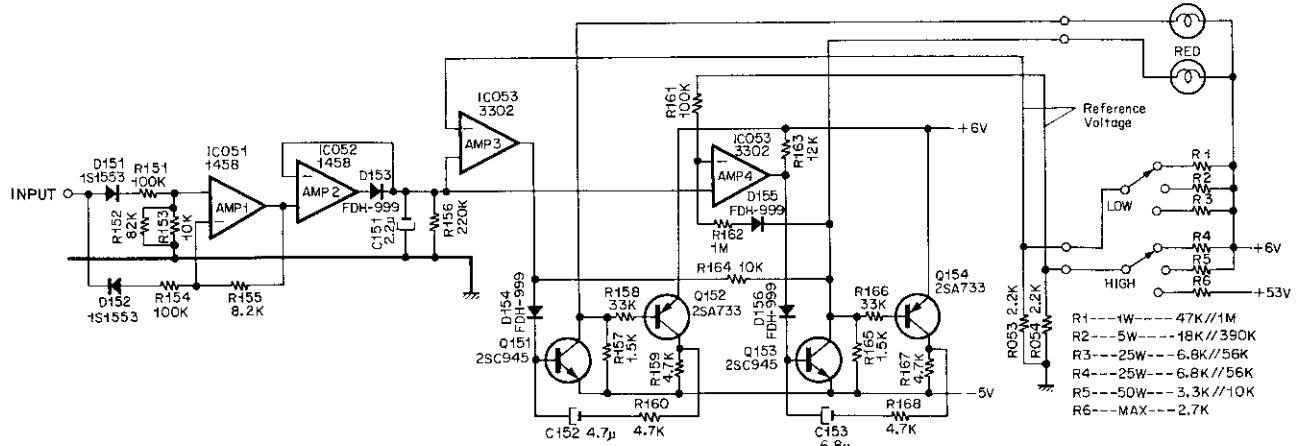

Fig. 2.8

3. REMOVAL PROCEDURES

3.1. Cabinet Ass'y

Refer to Fig. 3.1 and remove F01 and F02.

3.2. Rear Panel Ass'y

Remove cabinet ass'y (item 3.1). Refer to Fig. 3.2 and remove F01 and F02.

3.3. Lamp

Remove rear panel ass'y (3.2). Refer to Fig. 3.3 and remove F01 and F02, then remove F03, F04 and F05.

3.4. Switch

Remove rear panel ass'y (3.2). Refer to Fig. 3.4 and remove F01 and F02, then remove F03 and F04 (power sw.), and F05 and F06 (indicator sw. ass'y).

3.5. Power Block Ass'y

Remove cabinet ass'y (3.1). Refer to Fig. 3.5 and remove F01 through F04.

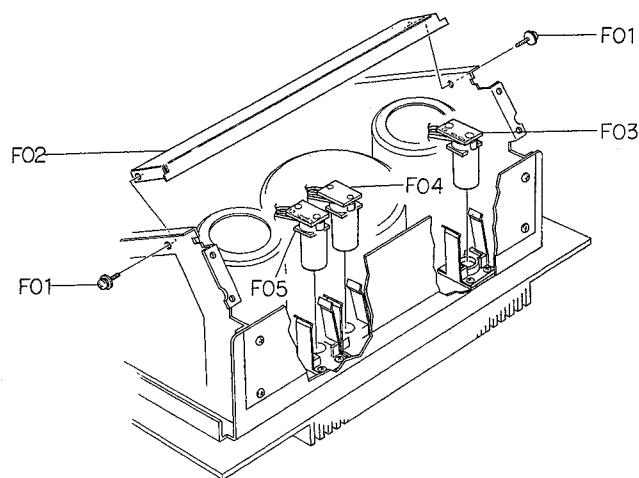

Fig. 3.3

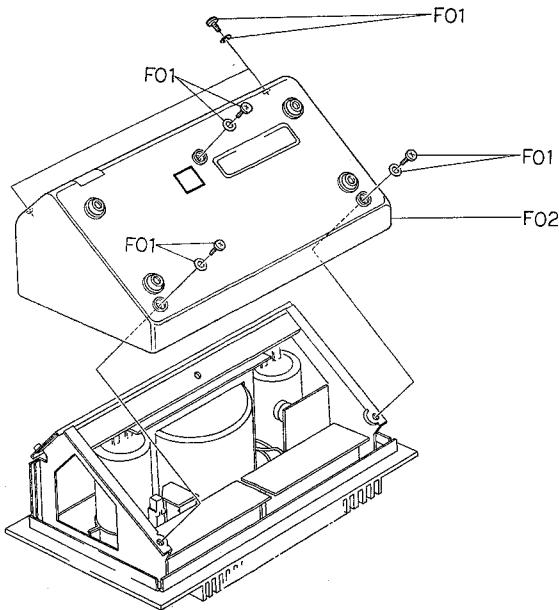

Fig. 3.1

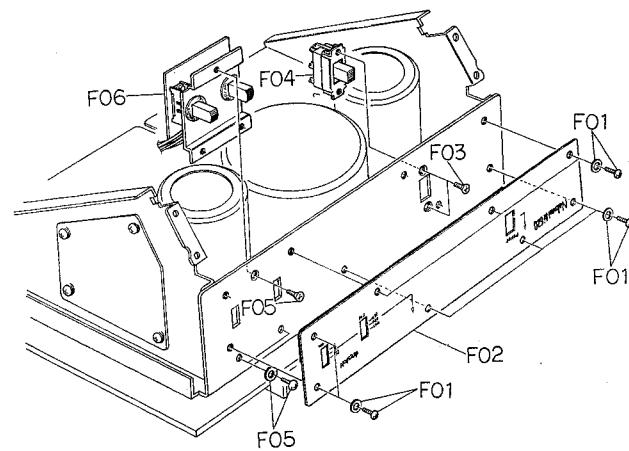

Fig. 3.4

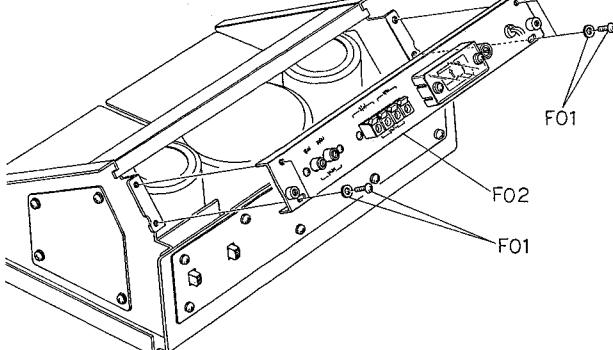

Fig. 3.2

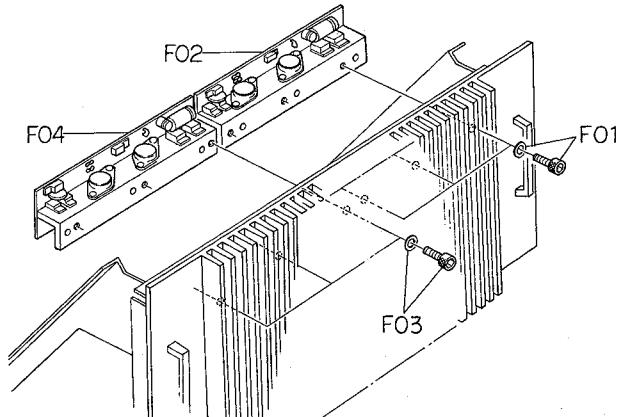

Fig. 3.5

3.6. Jack

Remove rear panel ass'y (3.2). Refer to Fig. 3.6 and remove F01 through F04 (2-pin jack) and F05 through F07 (push terminal).

3.7. Indicator P.C.B. Ass'y

Remove cabinet ass'y (3.1). Refer to Fig. 3.7 and remove F01 through F03.

3.8. Relay P.C.B. Ass'y and Cement Resistor

Remove cabinet ass'y (3.1). Refer to Fig. 3.8 and remove F01 and F02 (cement resistor), and F03 through F05 (relay P.C.B. ass'y).

3.9. Diode and Output P.C.B. Ass'y

Remove cabinet ass'y (3.1). Refer to Fig. 3.9 and remove F01 and F02 (diode), and F03 and F04 (output P.C.B. ass'y).

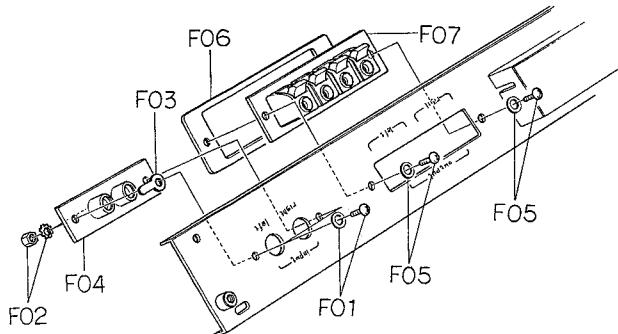

Fig. 3.6

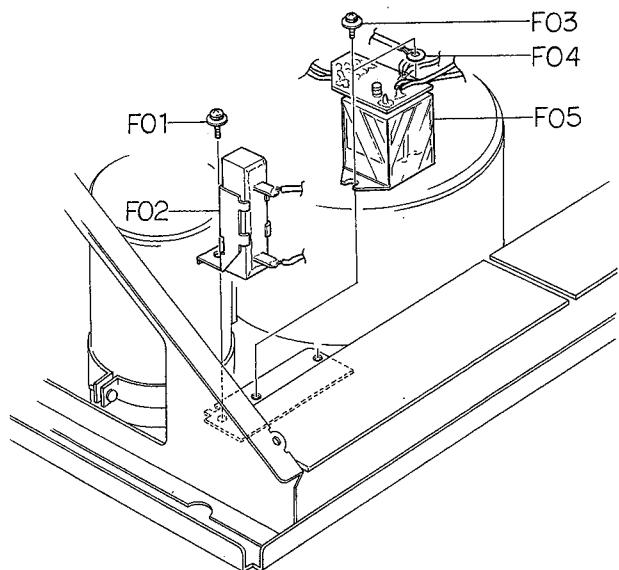

Fig. 3.8

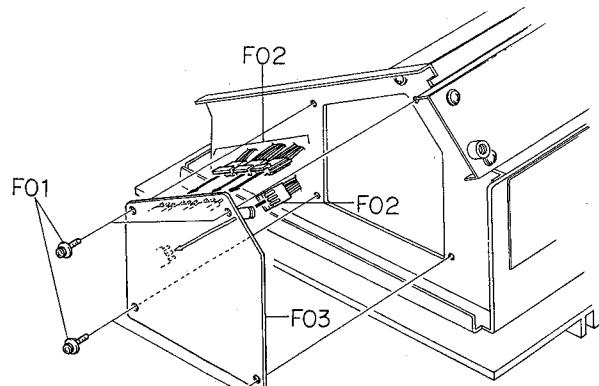

Fig. 3.7

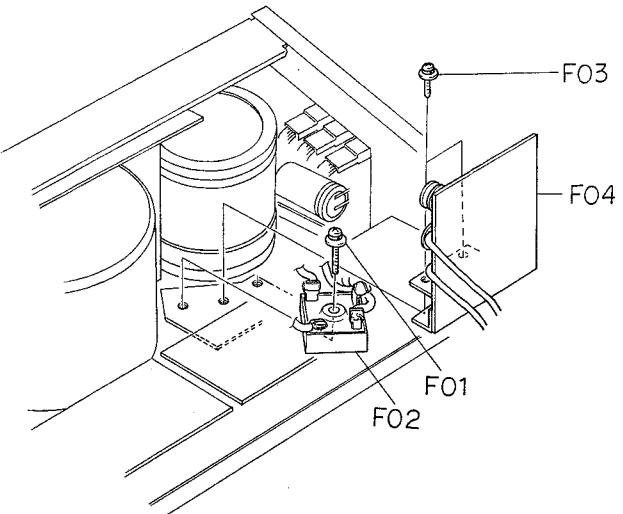

Fig. 3.9

3.10. Transformer and Capacitor

Remove cabinet ass'y(3.1). Refer to Fig. 3.10 and remove F01 through F06, F07 and F08 (transformer), F09 through F11 (capacitor) and F12 through F14 (capacitor).

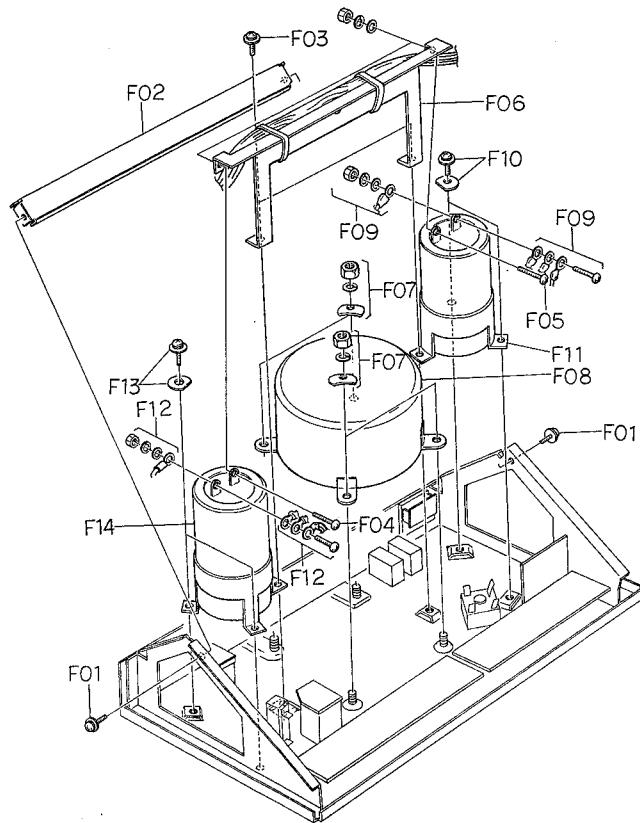

Fig. 3.10

4. READJUSTMENT OF POWER BLOCK

The 620 uses no semi-fixed parts to enhance reliability. As long as all parts meet the specification, the published characteristics can be obtained without readjustment. Generally, no readjustment is required if only defective parts are replaced at repair.

Observe the following precautions when repairing defective parts:

- 4.1. Relocating a wiring can cause larger distortion.
Do not relocate the wiring.
- 4.2. Fully tighten or retighten the screws on the chassis to decrease the resistance between GND terminals.
- 4.3. If a new semiconductor is installed in the power block, a perfect balance should be held between it and the existing semiconductors in the block. An imperfect balance can cause larger distortion or unwanted oscillation.
To maintain a good balance, connect an 8Ω 100W load resistance to the output terminal, measure distortion and check that it meets the following requirements: (In this case, the residual distortion factor of the instrument should be lower than the specified value.)
 - (1) Output 1 watt, 1 and 10 KHz input signals;
less than 0.005%
 - (2) Output 100 watts, 1 and 10 KHz input signals;
less than 0.007%

Described here are the possible causes for defects and the recommended remedial steps:

- (1) The characteristic of one transistor does not match that of the other transistor when they are used as a pair.

- (2) Usually, the idling current of power transistors Q019 and Q020 is approx. 20mA – 30mA. If it is lower, the distortion at 1 watt will increase. In such a case, solder additional $33K\Omega$ parallel to R018 and R019 ($33K\Omega$), respectively, from the dip side of the printed circuit board.
- (3) Improper locations of power supply wiring will increase the distortion at 100 watts.
- (4) If oscillation occurs, the distortion will become large at both 1 watt and 100 watts. Sometimes, oscillation cannot be observed even on a synchroscope if it involves frequencies as high as several MHz. Oscillation may have occurred if the distortion is large though the external operating voltage remains normal. Try the following steps to eliminate oscillation:
 - (a) Add ceramic capacitors of the same capacity parallel to C010 and C011 (0.047μ , 100V).
 - (b) Increase C013 (100pF) (by adding a 47pF in parallel) or decrease the capacitance (by replacing it with a 47p or removing it. If C013 is removed, make a short circuit by jumper wire.)
 - (c) Short R017 (27Ω) or increase it to 47Ω .

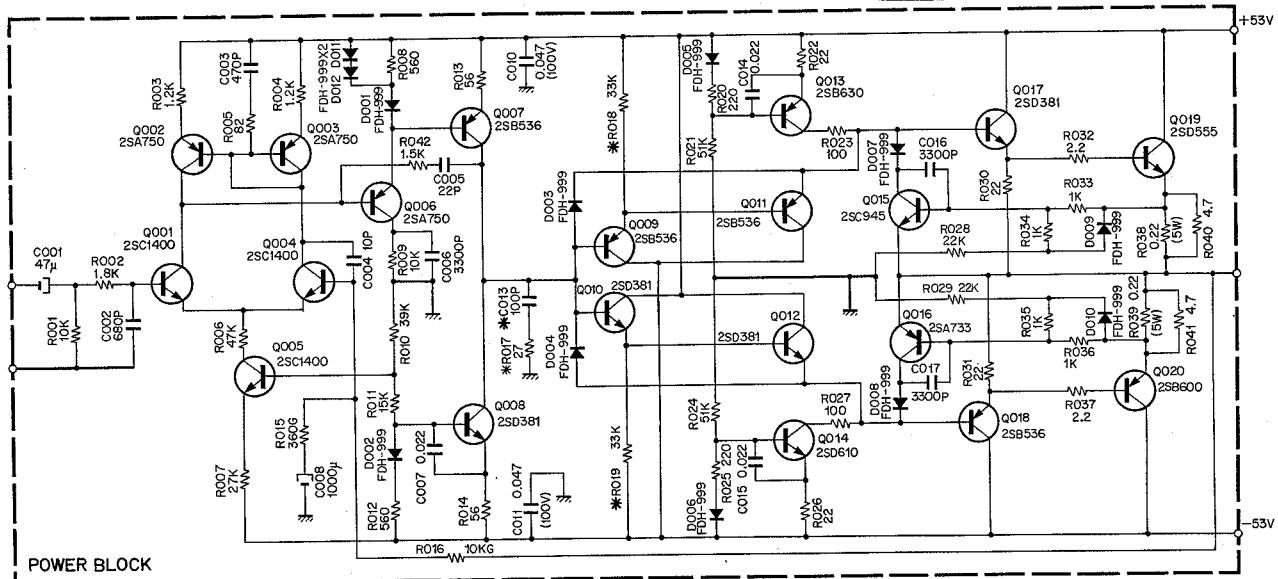

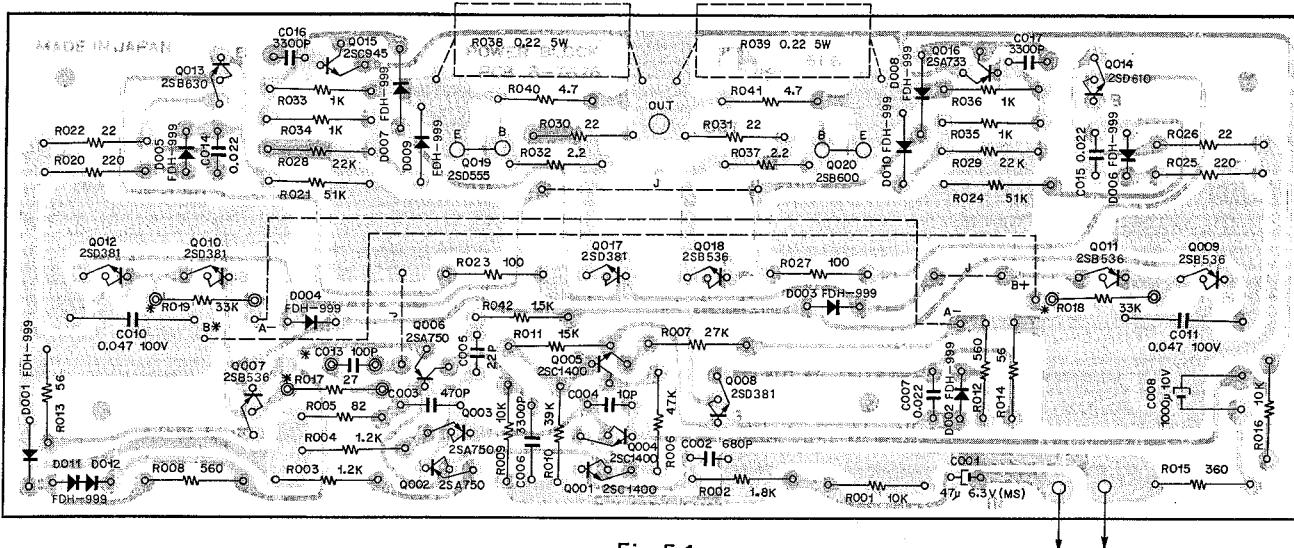

Fig. 4.

7. WIRING DIAGRAM

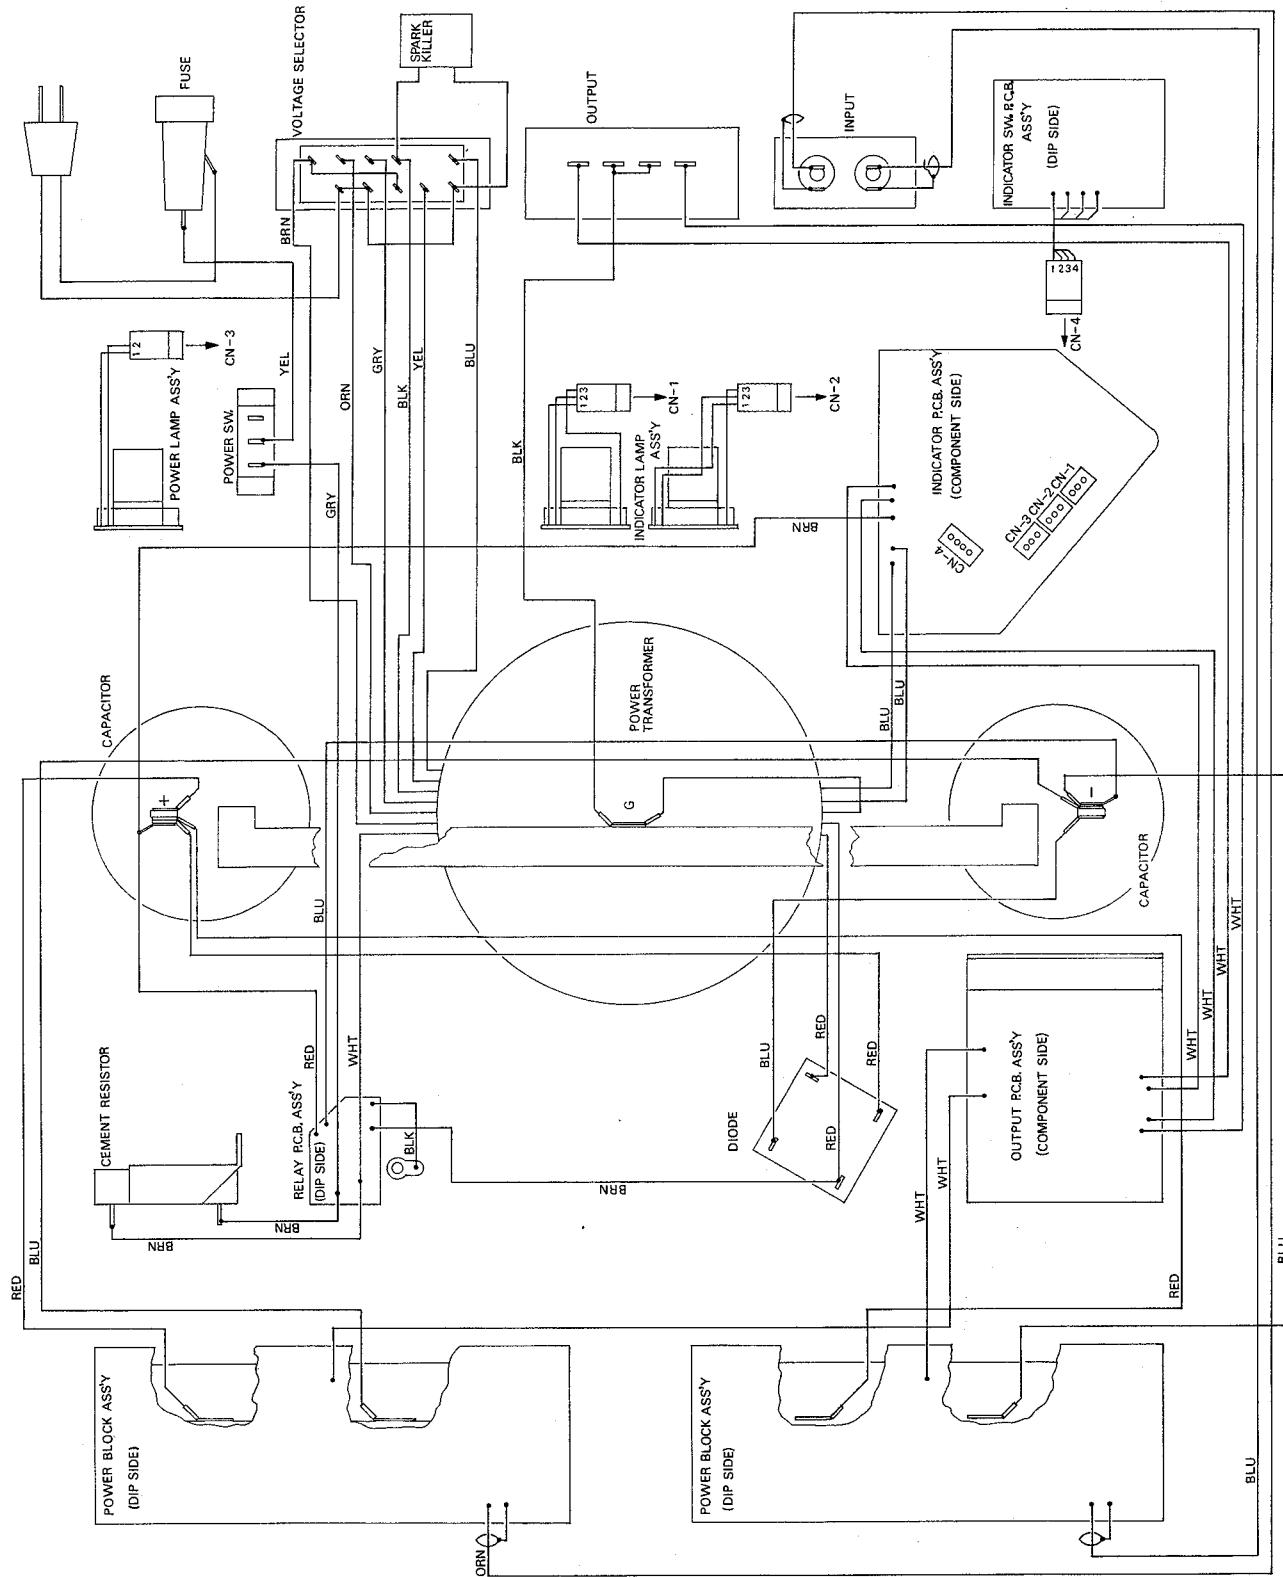

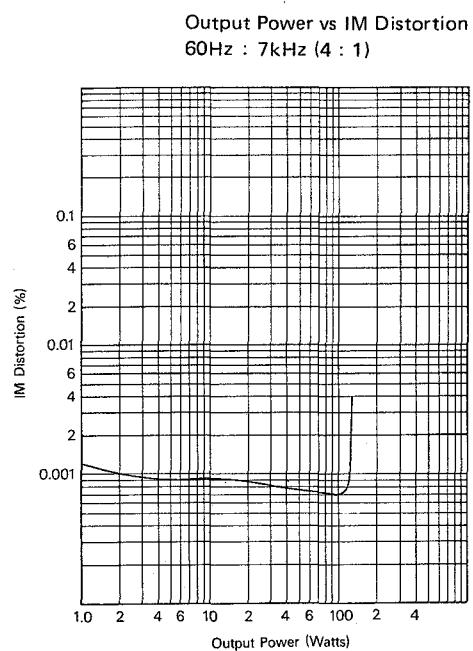

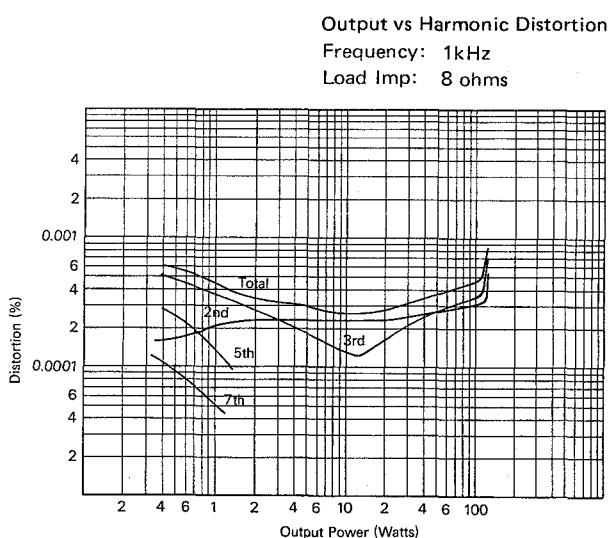

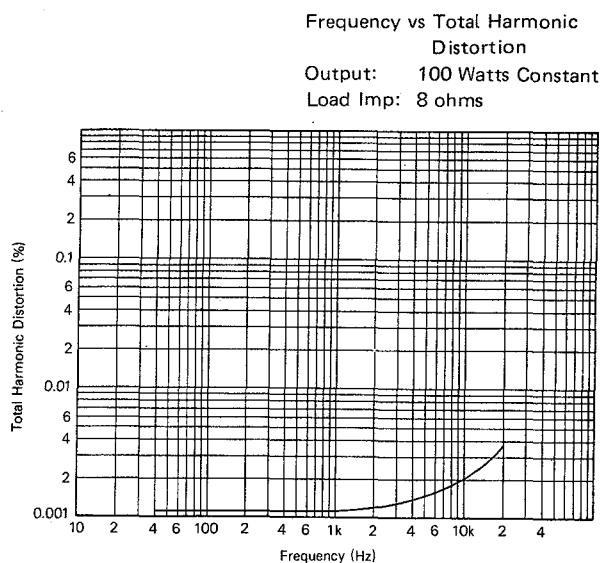

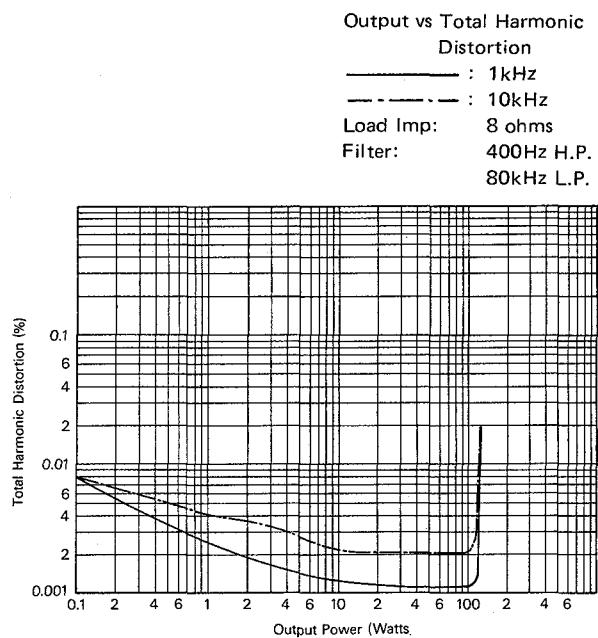

Fig. 7

8. PERFORMANCE DATA

The distortion data immediately above was obtained with the aid of a Brüel & Kjaer 3348 Real Time Analyzer. These measurements cannot be made with conventional distortion analyzers because of noise factors.

Fig. 8

9. BLOCK DIAGRAM

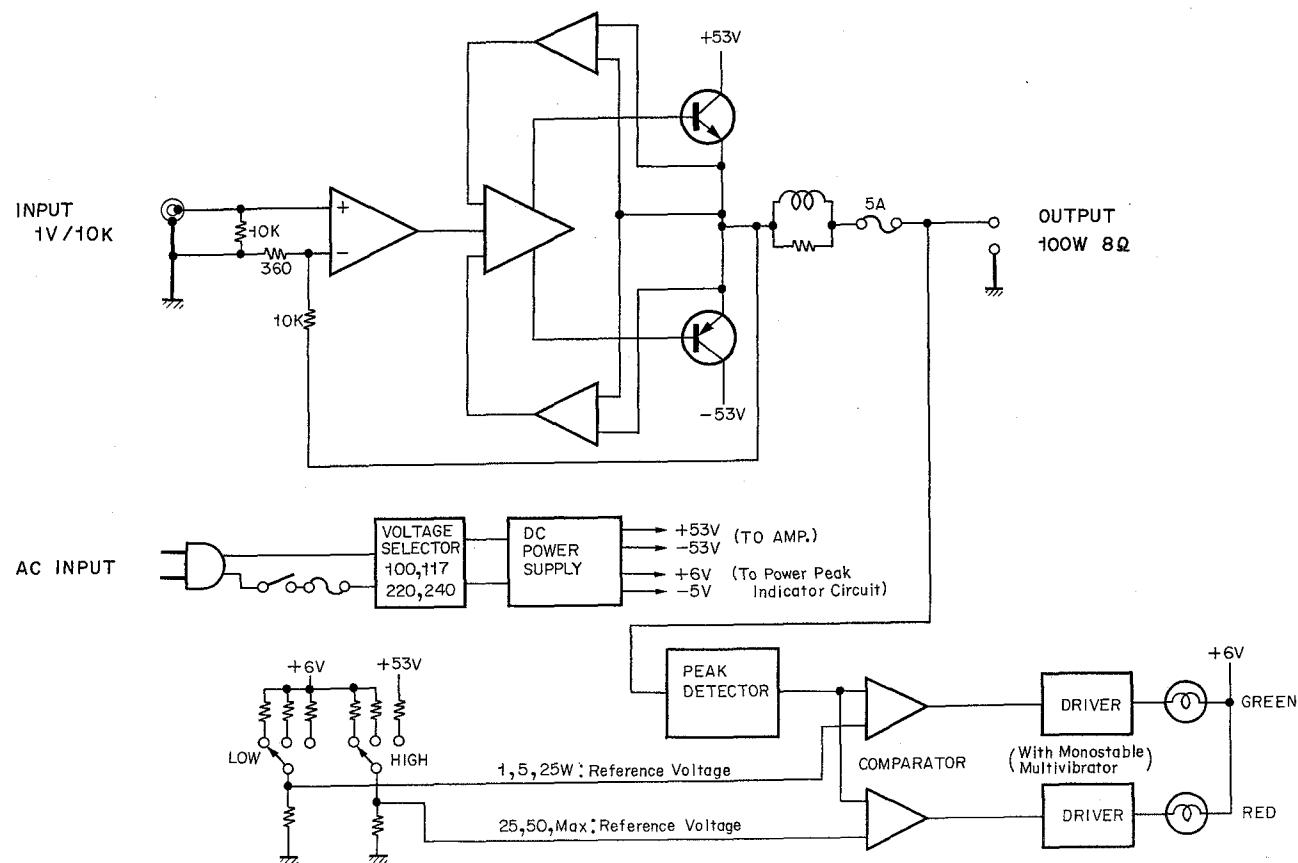

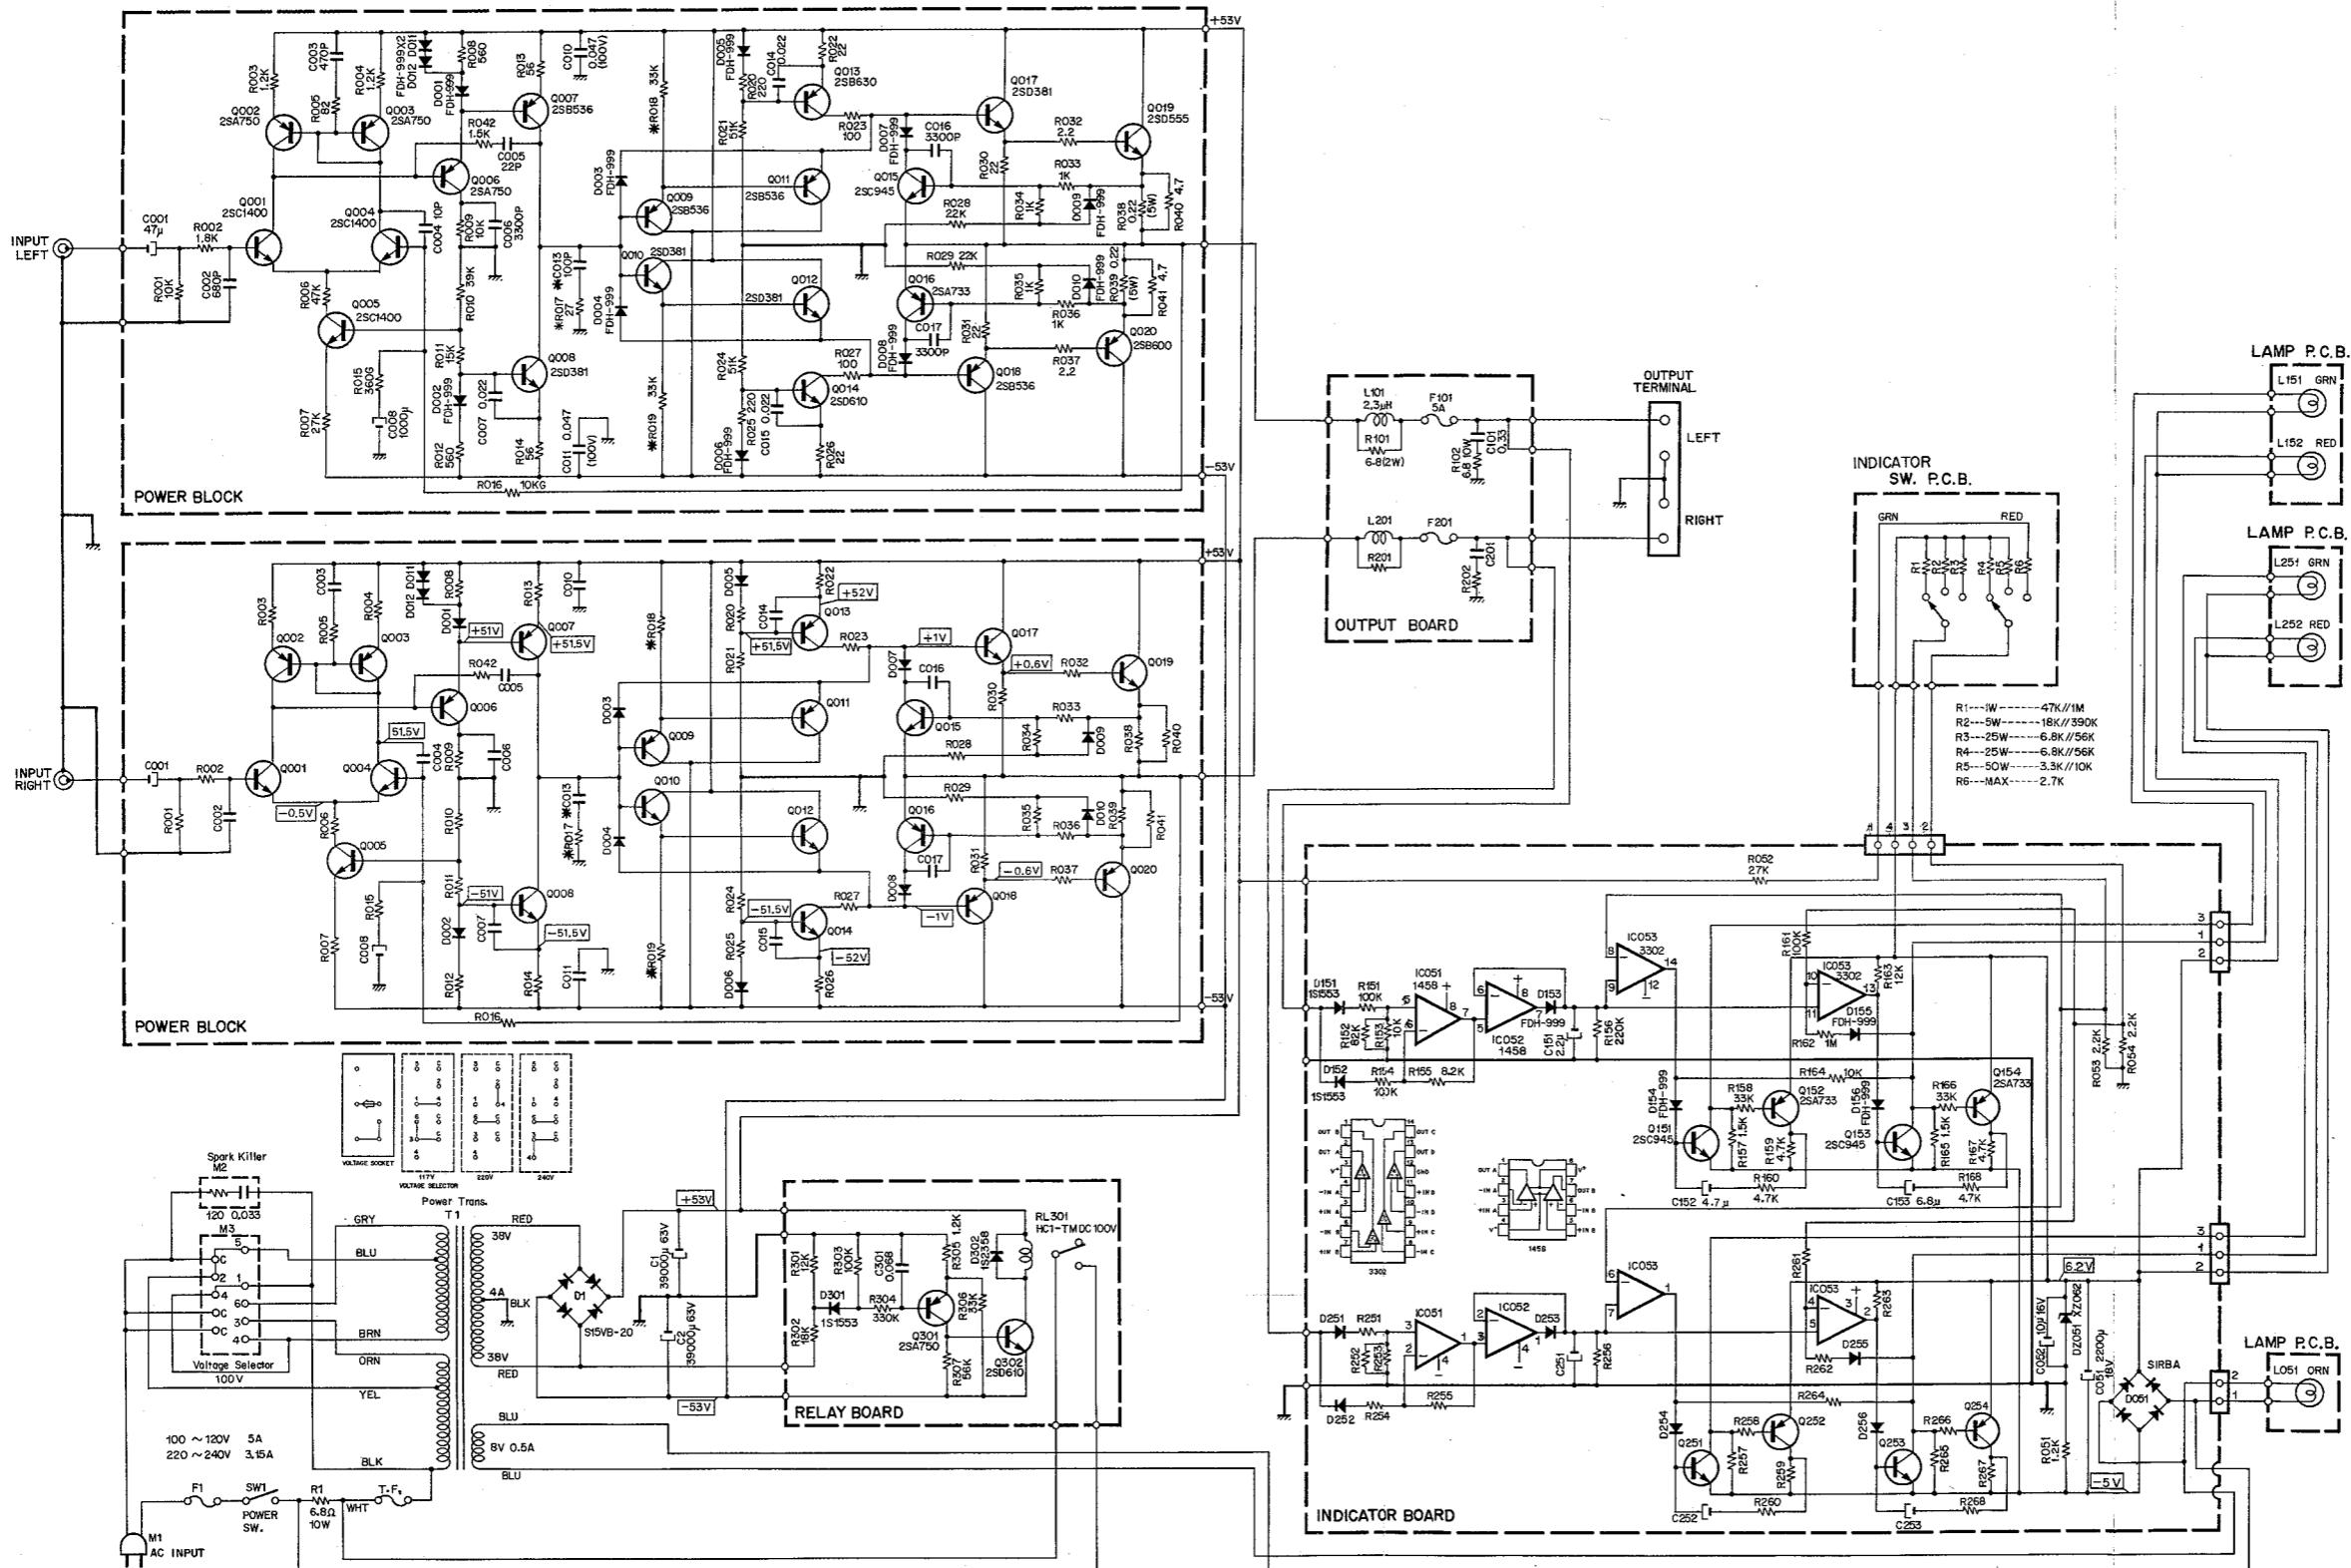

Fig. 9

10. SCHEMATIC DIAGRAM

Note: 1. [] shows the reference circuit voltage at approx. 30 watts output.

2. In the power block circuit, resistor R018,019 and capacitor C013 (* marks) are the parts for adjustment, and so typical value is shown.

Fig. 10

11. SPECIFICATIONS

Power Source	100/117/220/240 V AC, 50/60 Hz
Power Consumption	50 VA at idling 700 VA with both channels driven to clipping into 8 ohm loads
Power Output	100 Watts per channel minimum continuous sine wave ("RMS") at 8 ohms, 5-20,000 Hz with less than 0.01%THD 50 Watts per channel at 16 ohms
IHF Power Bandwidth	5 - 50,000 Hz for less than 0.1%THD (both channels driven) 5 - 20,000 Hz for less than 0.01%THD 5 - 10,000 Hz for less than 0.005%THD
Damping Factor	Greater than 100 (1 KHz, 8 ohms)
Total Harmonic Distortion	Less than 0.002% @ 1 KHz or below Less than 0.005% @ 10 KHz or below
Intermodulation Distortion	Less than 0.002% (60 Hz: 7 KHz, 4:1, 8 ohm load, 100 W output)
Frequency Response	5 - 100,000 Hz +0, -1 dB
Input Impedance	10 K ohms
Residual Noise Level	Less than 0.05 mV (IHF A Network) Less than 0.1 mV (linear)
Signal-to-Noise Ratio	Better than 120 dB at rated output (IHF A, input shorted)
Crosstalk	Better than -70 dB @ 1 KHz
Peak Power Indicators	Green at 1 W, 5 W, 25 W, selectable Red at 25 W, 50 W, Maximum (110-130 W) selectable (Response time: responds to 0.1 ms pulse - off after 0.3 sec)
Dimensions	15.75"(W) x 7.44"(H) x 9.76"(D) 400mm (W) x 189mm (H) x 248mm (D)
Weight	27.6 lbs. (12.5 kg)

- Specifications and appearance design are subject to change for further improvement without notice.

Service Information

Model Nakamichi 620 (Power Amplifier)
Serial No. from 4104902
Subject Addition of Protector Circuit

NAKAMICHI

No. OOD-M-0044 (1/5)
Date 1 September, 1977

I. General:

A. Purpose:

A protector circuit has been added to prevent speakers from breakage, as the breakage of transistors in 620 would induce possible breakage of the speaker.

Note: When the protector circuit is activated (speaker terminals shorted with relay contacts), the power supply for 620 is required to be once switched off so as to release the protecting function. The power should again be supplied for at least 5 minutes after switching off.

B. Modification:

Additional Parts:

Part No. BA03865A Protector P.C.B. Ass'y	1 pce.
0J03687A E.P. Stud A 2 pcs.
OE00030A Washer 3mm 1 pce.

Modified Parts:

Main Chassis Ass'y Part No. has been changed from JA03104A to JA03104B (including Protector P.C.B. Ass'y).

Mechanism Ass'y Part No. has been changed from JA03103A to JA03103B (including Protector P.C.B. Ass'y).

C. Principle of Operation:

The protector circuit aims at protecting the speaker with a shortcut from the speaker terminals to GND by operating the relay in Protector P.C.B. Ass'y when D.C. voltage is impressed between speaker terminals against any possible accident.

The time length required for protector to operate are specified as below according to D.C. voltages (either plus or minus) impressed between the speaker terminals:

D.C. Voltage between Speaker Terminals	Time required till Protector operates
50V DC	approx. 0.5 sec or less
20V DC	approx. 1.2 sec ± 30%

<u>D.C. Voltage between Speaker Terminals</u>	<u>Time required till Protector operates</u>
10V DC	approx. 2.5 sec ± 30%
5V DC	approx. 4 ~ 10 sec

Once the protector circuit is activated, the protecting state is retained until the power supply to 620 is disconnected to release it.

The power should be supplied after power capacitors are fully discharged (for approximately 5 minutes or more).

Note: The protector circuit in 620 may occasionally be activated if a high transient D.C. voltage is delivered from the preamplifier connected with 620 at the time when the power supply for the preamplifier is turned on.

The cause is not from any trouble in 620.

For its countermeasure, the power for 620 is recommended to be supplied last of all.

II. Parts List:

Part No.	BA03865A	Protector P.C.B. Ass'y 1 pce.
	OJ03687A	E.P. Stud A 2 pcs.
	OE00030A	Washer 3mm 1 pce.

III. Mounting Diagram and Schematic Diagram:

Refer to Figs. 2 and 3.

IV. Modification Procedures for the Current Models:

Following shows the way how to assemble the Protector P.C.B. Ass'y in the current Models.

A. Parts to be required:

Part No. BA03865A Protector P.C.B. Ass'y 1 pce.

OJ03687A E.P. Stud A 2 pcs.

OE00030A Washer 3mm 1 pce.

B. Modification Procedures:

Refer to Fig. 1.

1. Disassemble the Cabinet by removing five screws.
2. Remove two screws from the Relay P.C.B. Ass'y and replace with E.P. Studs. Note to add a washer as shown in the figure.
3. Loosen the screw which fixes the cement resistor 6.8Ω 10W to the chassis, then move the cement resistor to prevent contacting the Protector P.C.B. Ass'y.
4. Assemble the Protector P.C.B. Ass'y.
5. Disassemble the Rear Angle by removing two screws.
6. Solder the signal wires (WHT,WHT) of the Protector P.C.B. Ass'y to the speaker terminal (output terminal) plus side of both channels.
7. Solder the RED wire of the Protector P.C.B. Ass'y to the plus terminal (RED wires are already soldered) of the capacitor C1 39,000μF 63V.
8. Solder the BLU wire of the Protector P.C.B. Ass'y to the minus terminal (BLU wires are already soldered) of the capacitor C2 39,000μF 63V.
9. Bind these wires at an appropriate point.
10. Assemble the Rear Angle.
11. Assemble the Cabinet.
