

STEREO POWER AMPLIFIER

# SPEC-4

## SERVICE MANUAL

 PIONEER®

## MODEL SPEC-4 COMES IN TWO VERSIONS DISTINGUISHED AS FOLLOWS:

Type	Voltage	Remarks
KU	120V only	U. S. A. model
S	110V, 120V, 220V and 240V (Switchable)	General export model

- This service manual is applicable to KU(p2-p40) and S(p41-p48) types.
- For servicing of S type please refer to KU type with the exception of descriptions in the Additional Service Manual (p41-p48).

### NOTE:

Specifications and the design subject to possible modification without notice due to improvements.

## 2. FRONT PANEL FACILITIES

### POWER SWITCH

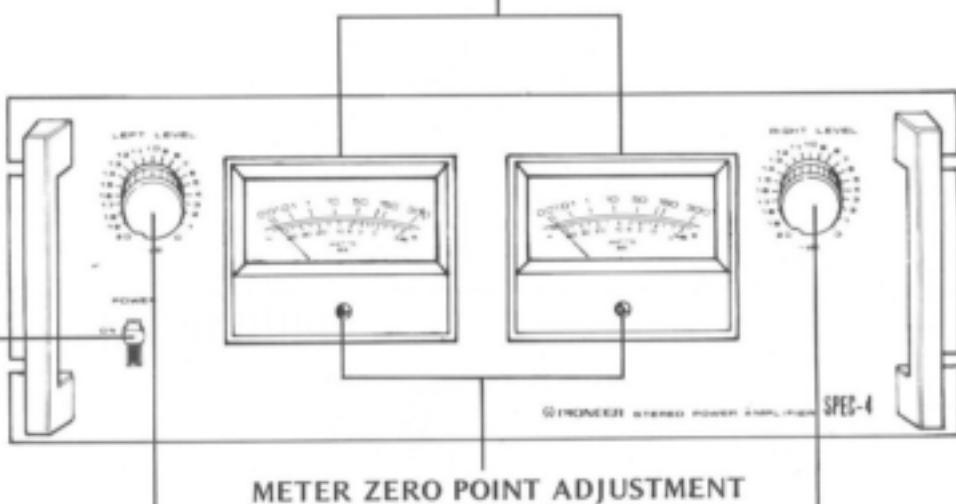

Set to ON position to energize SPEC-4. After setting to ON, there is a brief delay before sound is obtained. This is due to the operation of the muting circuit which prevents noise when the POWER is switched. This function does not indicate difficulty and normal operating condition is attained in a several seconds.

### PEAK LEVEL METERS

When speaker systems of 8ohm nominal impedance are connected, these provide direct readout of the peak output power in Watts.

*NOTE:*

*Speaker system impedance varies according to frequency. To obtain a precise measurement of the output power, remove speaker connections and connect 8ohm dummy loads across the SPEAKER terminals.*

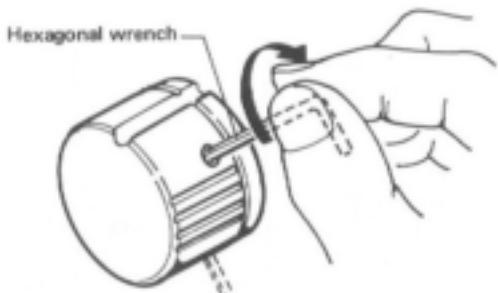

### INPUT LEVEL CONTROLS (LEFT & RIGHT)

Adjust the LEFT and RIGHT controls according to the output level (voltage) of the preamplifier connected to the SPEC-4's INPUT (L, R) terminals. If the controls are turned fully to the right (to the "0dB" position), then the rated input will be 1V. Conversely, if they are turned to the left, this will yield an attenuation equal to the graduations, and the rated power output can be varied. Standard input voltages are: 0dB = 1V, -6dB = 2V, -10dB = 3V, -12dB = 4V, and -14dB = 5V.

*NOTE:*

*Turn the controls counterclockwise to the 0dB position if you are using a preamplifier with a maximum output voltage of less than 1V. In such cases, it will not be possible to yield the rated power output listed in the SPEC-4's specifications. (For example one-quarter of the power output is obtained with a preamplifier having a maximum output of 0.5V.)*

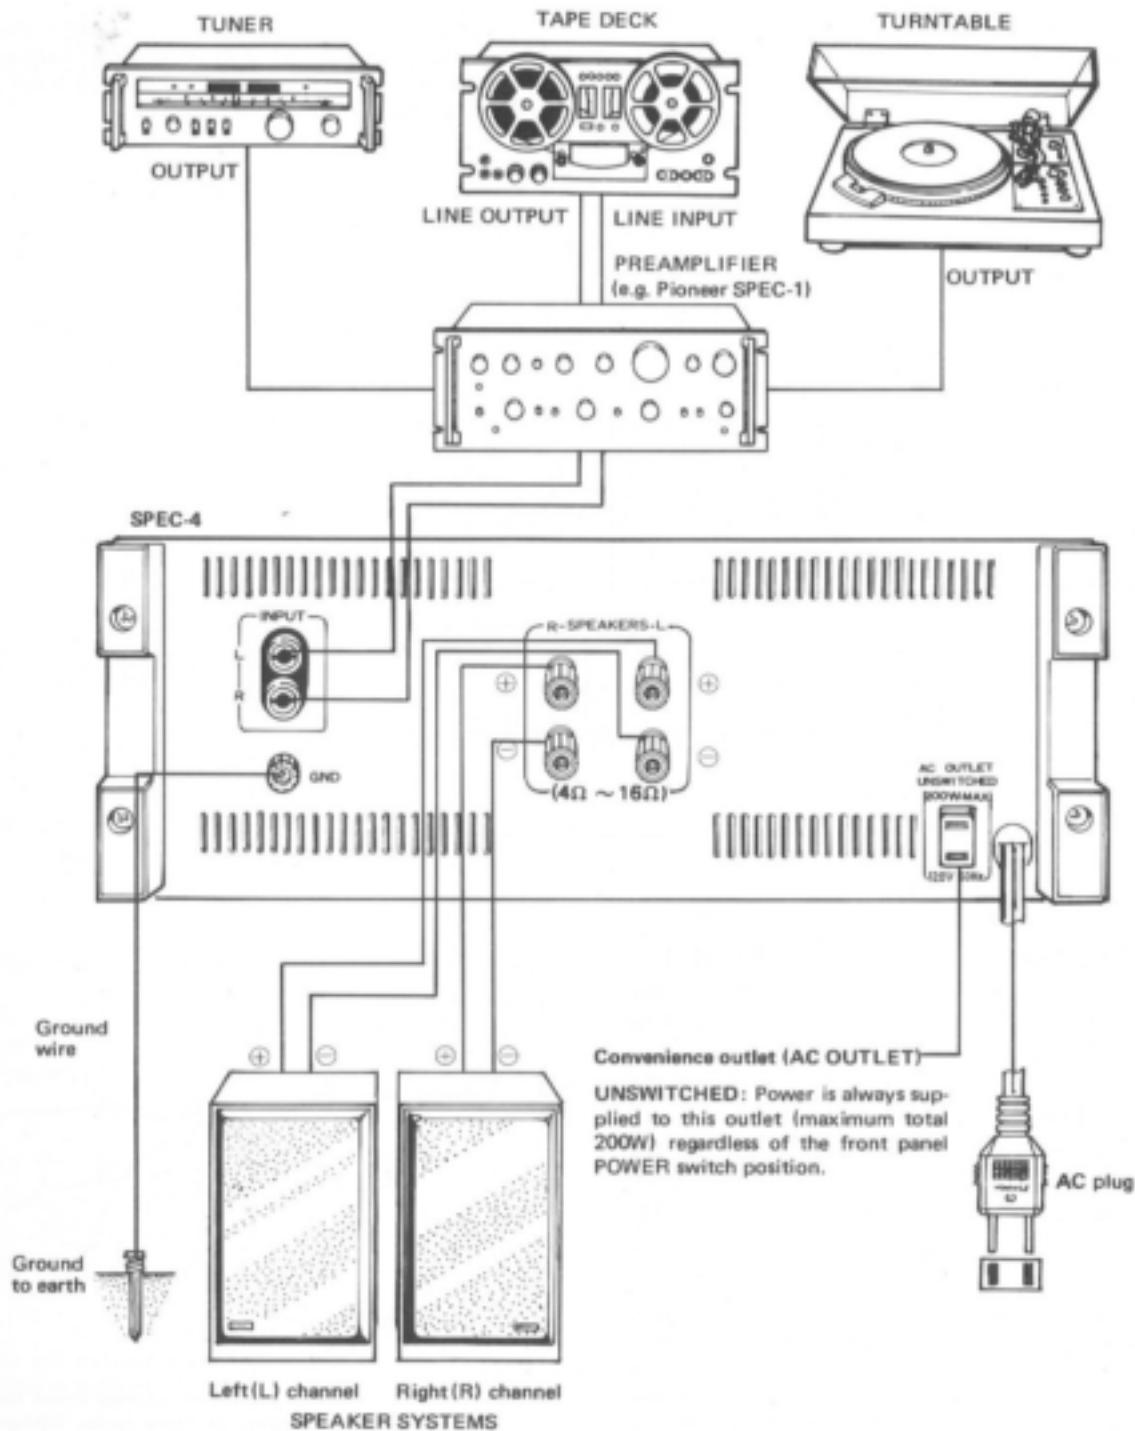

### HEXAGONAL WRENCH

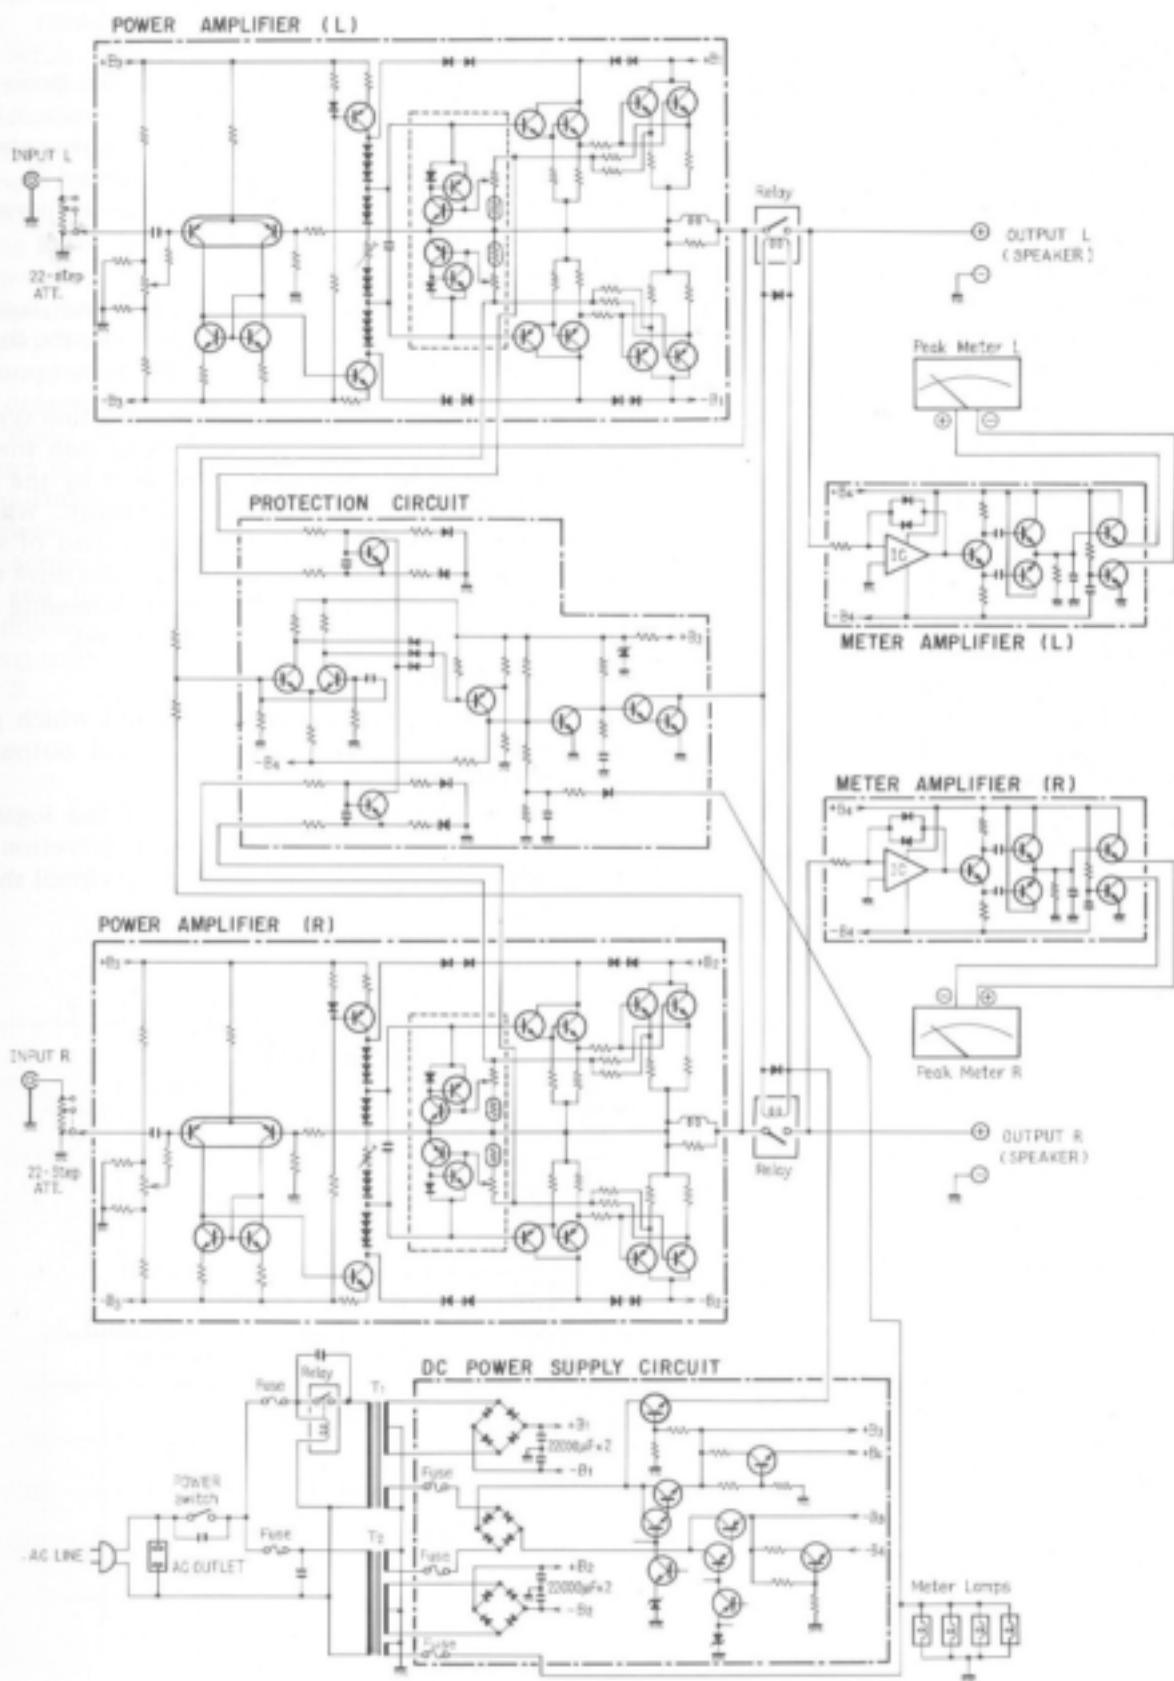

If any of the control knobs should happen to come loose, tighten by means of the hexagonal wrench.

### 3. CONNECTION DIAGRAM

Before making the connections, check that the power is off. Also, make sure that you turn the power off if you want to change over the connections when the components are operating.

## 4 BLOCK DIAGRAM

# 5. CIRCUIT DESCRIPTION

## 5.1 POWER AMPLIFIER

This unit is a DC amplifier with an input coupling capacitor. Generally, in direct coupled amplifiers, 100% NFB is applied at the DC stage. This technique provides a DC gain of 1 and stabilizes the circuit. The operation is performed by giving the NFB circuit a time constant. However, this adversely effects the low range phase characteristics in the audio frequency range.

Careful consideration has been given to stability in the circuit design of this unit; the time constant of the low range of the NFB circuit has been eliminated, and amplification is performed up to the DC stage. This improves the low range phase characteristics and tonal quality. Moreover, the low range frequency response is determined by the time constant of the input coupling section.

The first stage is a PNP dual transistor differential amplifier with a current mirror circuit, which enables stable operation and provides high gain from the DC to the ultrahigh frequency range.

The second stage (predriver stage) is a Class A amplifier. High voltage gain is obtained by inserting a constant current circuit for the load (voltage gain is necessary at this stage because the voltage gain of the power stage is zero). The power stage is a 3-stage Darlington connection and the final stage is a parallel SEPP.

A power limiter circuit protects the power stage. D<sub>1</sub>, D<sub>2</sub>, D<sub>3</sub> and D<sub>4</sub>, D<sub>5</sub>, D<sub>6</sub> are drive voltage limiters which prevent overdriving of the power stage. D<sub>3</sub>, D<sub>6</sub> shift the DC level of the signal and D<sub>1</sub>, D<sub>2</sub>, D<sub>4</sub>, D<sub>5</sub> conduct the overdrive voltage to prevent the power stage being overdriven.

### NOTE:

*Since the power supply voltage of the power stage is lower than that of the drive stage at high outputs, D<sub>1</sub>, D<sub>2</sub> and D<sub>4</sub>, D<sub>5</sub> conduct the overdrive voltage.*

The power limiter is a current-detection type. This limiter detects the current forced thru the power transistor by the voltage generated by the emitter resistance of the power transistors. When the output has exceeded 180W at a load of 4 ohms or less, Q<sub>13</sub> — Q<sub>16</sub> operate to limit the drive voltage. This prevents the output from increasing even if an input greater than this is applied.

## 5.2 METER AMPLIFIER

A peak output meter is provided which permits direct reading of an 8 ohms load output from 0.01W to 300W.

The meter amplifier consists of the logarithmic compression circuit, absolute value detection circuit, peak hold circuit, and meter drive circuit shown in Fig. 2.

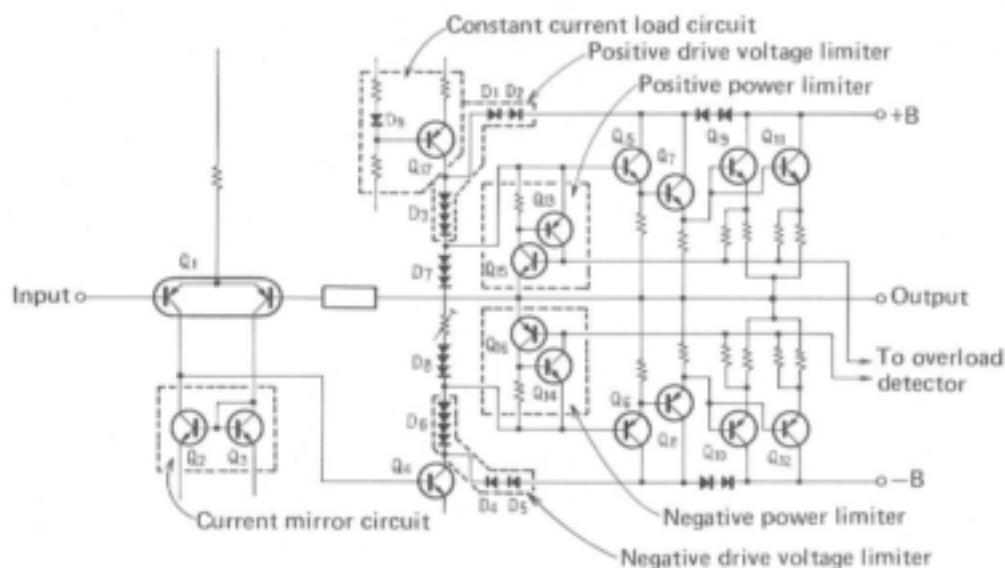

Fig. 1 Power amplifier circuit

The input signal is divided by  $R_1$ ,  $R_2$  and sent to the logarithmic compression circuit. The logarithmic compression circuit is an audio IC (TA7136P2) and utilizes the rise characteristic of diodes  $D_1$ ,  $D_2$  in the NFB loop to reduce the dynamic range of the signal. This creates an input/output characteristic which attenuates low level inputs very little and high level inputs substantially. The characteristic is compensated by inserting  $R_4$  in parallel with  $D_1$ ,  $D_2$  and the circuit is temperature compensated with a thermistor so that the meter scale is almost logarithmically graduated from 0.01W to 300W.

The compressed signal is applied to the absolute value detector. This circuit produces a reverse phase signal by means of  $Q_2$  and extracts and combines the positive half cycle by means of  $Q_3$  and  $Q_4$ . This signal charges  $C_1$  up to the peak value and drives the meter by means of  $Q_5$ ,  $Q_6$ . The charge across  $C_1$  is discharged at the time constant of  $C_1$  and  $R_5$  to determine the fall time of the peak indication of the meter.

The frequency response of the peak meter is given in Fig. 3.

### 5.3 PROTECTION CIRCUIT

This circuit protects the power transistors in case of overload, the speakers in case of power amplifier malfunction, and also performs a muting function when the power supply is turned ON or OFF. The protection circuit is composed of three sections (Fig. 4).

#### 1. Relay Driver Circuit (Fig. 5)

The relay which connects the output circuits is driven by this circuit. It also performs a muting function to prevent unpleasant noise during ON-OFF operation of the power supply as well as opening the output circuit on command from the detector circuits.

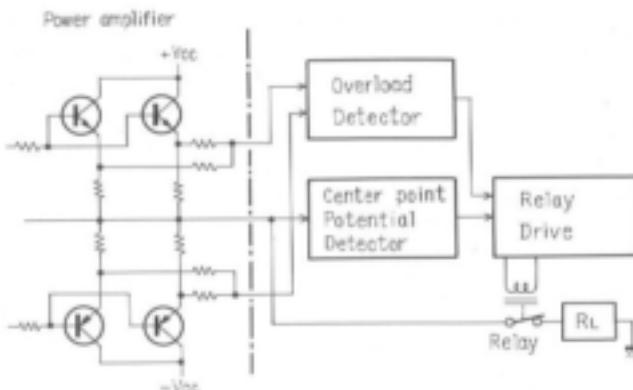

Fig. 4 Block diagram of protection circuit

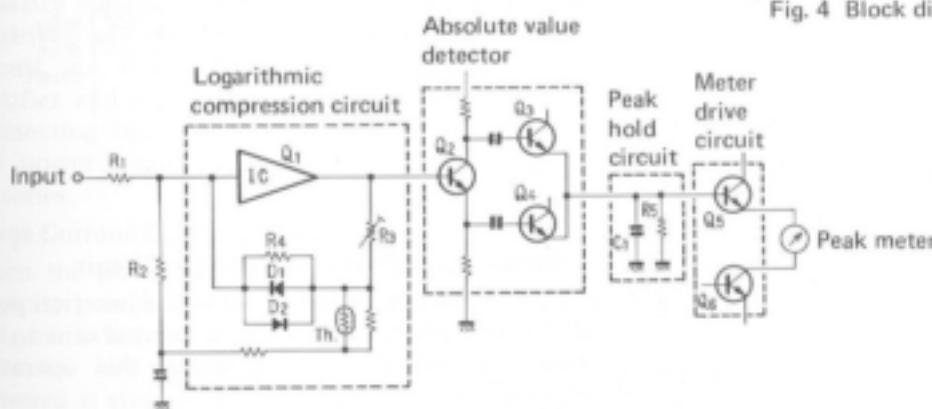

Fig. 2 Meter amplifier circuit

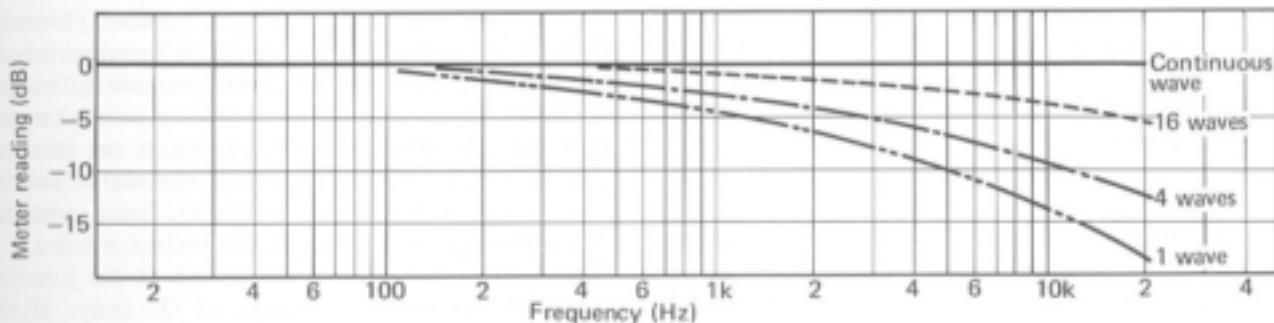

Fig. 3 Frequency response of the peak meter

## Muting Operation

When the power supply is turned ON,  $Q_{11}$  base is reverse biased through  $D_2$  and  $R_{22}$ , turning  $Q_{11}$  OFF.  $Q_{12}$  base potential rises as  $C_1$  charges through  $R_1$  &  $R_2$ , and  $Q_{12}$  &  $Q_{13}$  turn ON several seconds later. The collector current of  $Q_{13}$  then flows through the relay coil, operating the relay to turn on the power amplifier output circuit. The reverse bias of  $Q_{11}$  base from  $D_2$  &  $R_{22}$  disappears when the power supply is set from ON to OFF.  $Q_{11}$  remains ON however, due to the residual power supply voltage.  $C_1$  very rapidly discharges,  $Q_{12}$  base potential drops and  $Q_{12}$  &  $Q_{13}$  turn OFF. The relay releases and the power amplifier output circuit turns OFF.

### NOTE:

$Q_{10}$  is normally OFF due to base bias and does not participate in the muting operation.

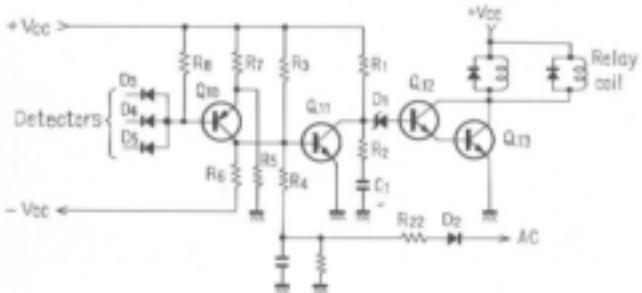

Fig. 5 Relay drive circuit

## Operation by Detector Circuit Command

Command from the detector circuits pass through one of  $D_3$ ,  $D_4$  or  $D_5$  and are applied in the form of a current flow.  $Q_{10}$  is normally reverse biased through  $R_8$ , but when a large current flows through one of these diodes,  $Q_{10}$  base potential declines according to the voltage drop at  $R_8$ .  $Q_{10}$  then turns ON,  $Q_{11}$  base potential rises and  $Q_{11}$  turns ON.  $C_1$  rapidly discharges and  $Q_{12}$  base potential drops, turning  $Q_{12}$  &  $Q_{13}$  OFF. The relay releases and the power amplifier output circuit becomes cut off.

## 2. Overload Detector Circuit

Shorting of the power amplifier load or a load impedance below the specified value causes a command to be sent to the relay drive circuit. This is illustrated in Fig. 6.

With the output stage in class B operation, when  $Q_a$  is operating in the positive half cycle,  $Q_b$  becomes cut off and the signal current flows as indicated by the solid arrows in Fig. 6. Point D potential at this time is the point A potential divided by  $R_{49}$  and  $R_{50}$ . Also, point C potential is

the point A potential divided by  $R_{e1}$  and  $R_L$  (load). Point D is connected to  $Q_{12}$  base and point C to  $Q_{12}$  emitter through  $R_{48}$  and  $R_{e2}$ . When  $R_L$  is extremely small, the point C potential becomes considerably lower than point D. This potential difference forward biases  $Q_{12}$ .  $Q_{12}$  turns ON and current flows in  $D_3$ .

$Q_b$  operates in the negative half cycle and  $Q_a$  becomes cut off. The signal flows is indicated by the broken line arrows in the center of Fig. 6.  $Q_{12}$  is biased by the potential difference between point C and point E. If  $R_L$  is extremely small, the point C potential becomes considerably higher than that of point E.  $Q_{12}$  turns ON and current flows in  $D_3$ .

If large current flows in  $Q_a$  and  $Q_b$ ,  $Q_{12}$  becomes ON due to the  $R_{e1}$  and  $R_{e2}$  voltage drops, and current flows in  $D_3$ .  $C_{24}$  prevents faulty operation due to external noise.

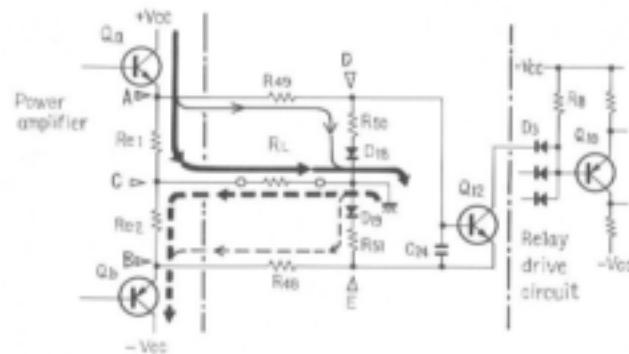

Fig. 6 Overload detector

## 3. Center Point Potential Detector Circuit

If a DC potential is produced at the junction point of the power amplifier, a command is sent to the relay drive circuit. Fig. 7 shows this operating principle.

$Q_8$  and  $Q_9$  compose a differential amplifier. When the same input is applied to both input terminals ( $Q_8$  and  $Q_9$  bases), no output is present. However, if there is a difference between the terminal inputs, the difference is amplified and becomes the output between the two collectors. During normal operation, an AC signal only is present at the junction point. As  $C_3$ ,  $C_4$  reactance is sufficiently low, the same signal is applied to  $Q_8$  and  $Q_9$  bases, resulting in an absence of output at the collector sides.

When a DC potential is produced at the junction point, it becomes the input of  $Q_9$  only. If the voltage is negative,  $Q_9$  collector current declines.

and at  $Q_8$  the collector current increases and the potential drops, causing current to flow through  $D_5$ .

If the DC voltage is positive,  $Q_9$  collector current increases and the potential drops, while at  $Q_8$  the collector current decreases and the potential rises. Current therefore flows through  $D_4$ .

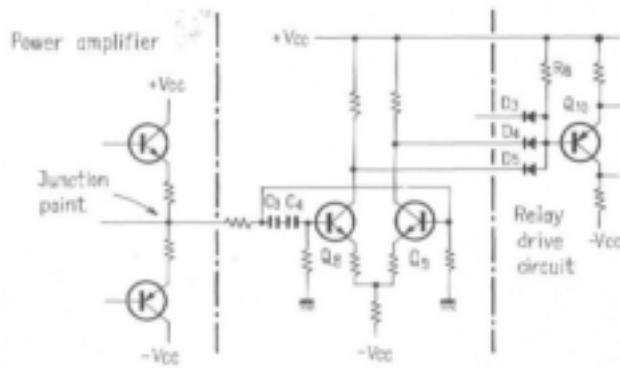

Fig. 7 Center point potential detector

### 5.3 POWER SUPPLY CIRCUIT

Two power transformers are used. The left channel and right channel power stage power supplies are independent. Power is supplied to each channel by a bridge rectifier and two  $22,000\mu F$  high capacity capacitors. The power supply before the predriver and for the main amplifier, protection circuit, etc. is supplied to each part thru a bridge rectifier and minus and plus voltage regulators by connecting the windings (different from that of the power stage) of the two power transformers in series.

#### Surge Current Countermeasures

When the power of an amplifier having two high capacity power supplies such as this unit is turned ON, an extremely large rush current flows. The time the left and right power transformers are powered is staggered somewhat in this amplifier to reduce this rush current to a minimum.

When the power switch is turned ON,  $T_2$  (right channel power transformer) is immediately powered, but since the relay contacts are open,  $T_1$  (left channel power transformer) is not powered. When current flows in the coil of the relay, the relay contacts are closed and  $T_1$  is powered. The rush current is reduced by one half during this 7–9msec delay.

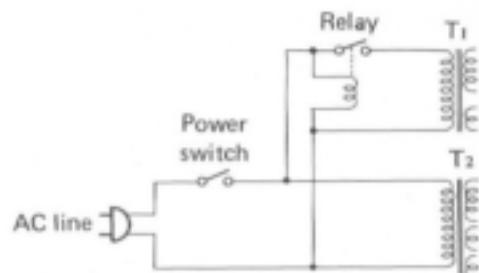

Fig. 8

### 5.5 OTHERS

The electrolytic capacitor ground connection is a  $20\text{mm} \times 2\text{mm}$  copper plate. A cord (inner conductor  $2.03\phi$ ,  $0.254\phi \times 41$  stands) having a DC resistance of about  $1/4$  that of common electric wire is used in the power supply, output, and ground circuits.

The input attenuator covers the 0 to  $-20\text{dB}$  range in 22 steps. The final position is  $-\infty$ .

## 6. DISASSEMBLY

### Top cover

Remove the 12 screws(A) to detach the top cover.

### Front panel

Loosen the set screws of the 2 LEVEL knobs with an hexagonal wrench and remove all the knobs.

Remove the 8 screws(B) and 2 nuts(D) to detach the front panel.

### Bottom plate

Remove the 17 screws(C) at the bottom plate and lift off the bottom plate.

# 8. ADJUSTMENTS

## 8.1 POWER AMPLIFIER

### DC Balance Adjustment

Do not connect load to speaker output terminals. Set LEVEL control to minimum (fully counter-clockwise).

Adjust VR<sub>1</sub> for 0V at the speaker output terminals (between + and -).

### Idle current Adjustment

Do not connect load to speaker output terminals. Set LEVEL control to minimum (fully counter-clockwise).

Adjust VR<sub>2</sub> for 50mV between terminal No. 26 (+) and No. 16 (-). Confirm that  $50\text{mV} \pm 10\text{mV}$  appears between terminals No. 25 (+) and No. 17 (-). Readjust after power has been applied for more than 10 minutes.

### Power Limiter Adjustment

Connect a 4 ohms resistor and distortion meter, oscilloscope, and AC voltmeter to the speaker output terminals (See Fig. 11). Apply a 1kHz signal to the input terminals and adjust the input signal level for a 200W ( $28.29\text{V}/4\Omega$ ) output. At the same time, adjust VR<sub>3</sub>, VR<sub>4</sub> for a distortion of 0.03%. VR<sub>4</sub> adjusts the positive half cycle limiter and VR<sub>3</sub> adjusts the negative half cycle. Observe the waveform with the oscilloscope and adjust so that the waveform is symmetrical.

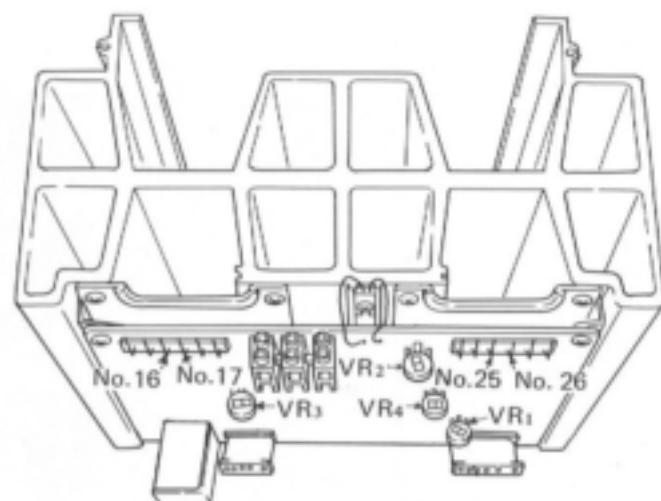

Fig. 10 Power amplifier

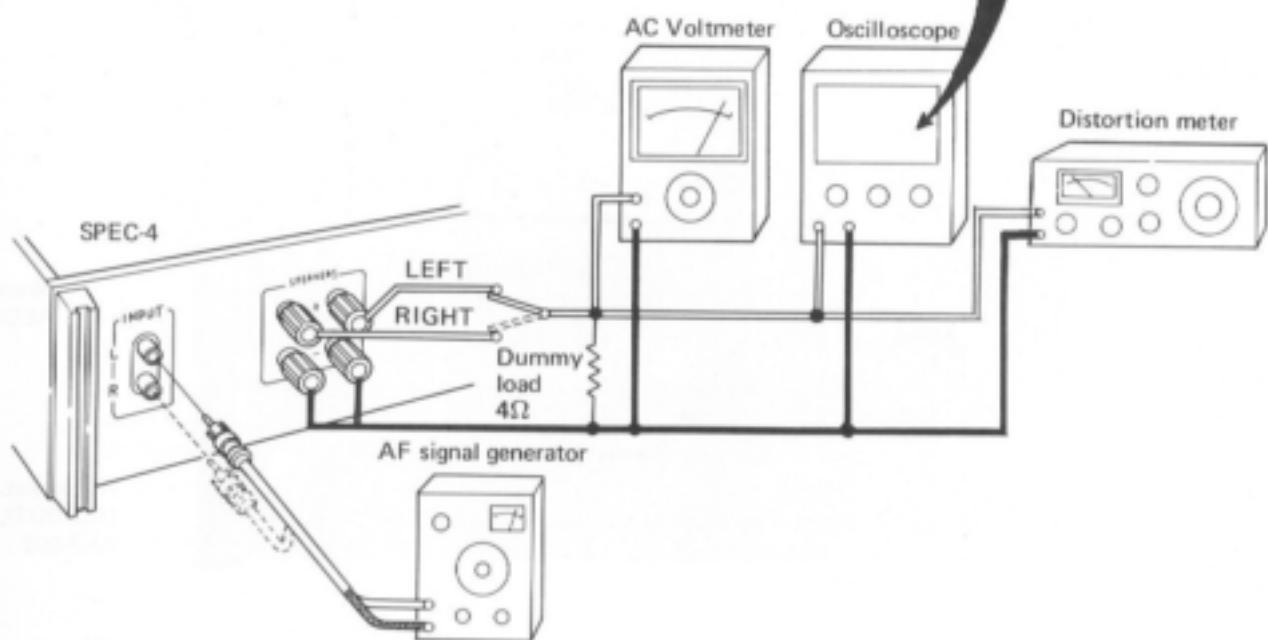

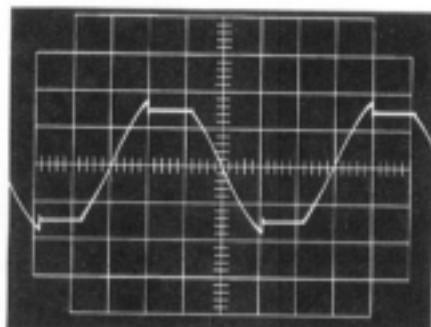

Fig. 11 Connection diagram for power limiter adjustment

## 8.2 METER AMPLIFIER

Connect an AC voltmeter to the speaker output terminals and apply a 1kHz signal to the input terminals and adjust the input signal level so that the voltmeter indicates 34.64V. At the same time, adjust VR<sub>1</sub> (R channel) and VR<sub>2</sub> (L channel) so that the output meter indicates 0dB.

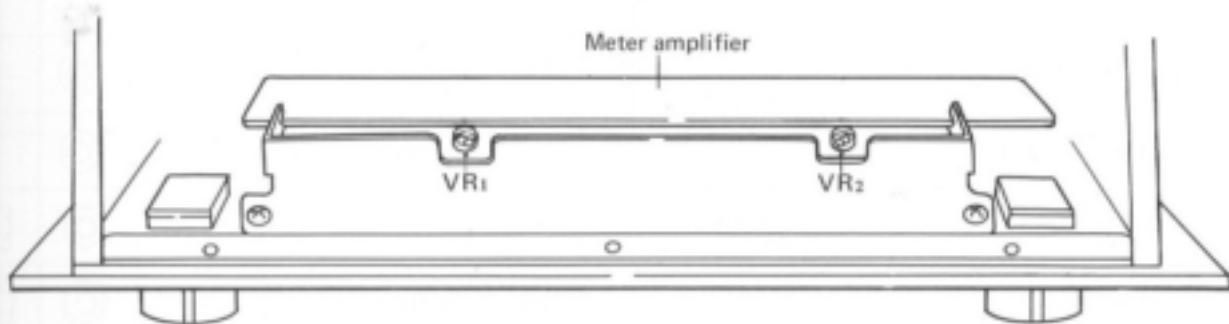

Fig. 12 The position of VR<sub>1</sub> and VR<sub>2</sub>

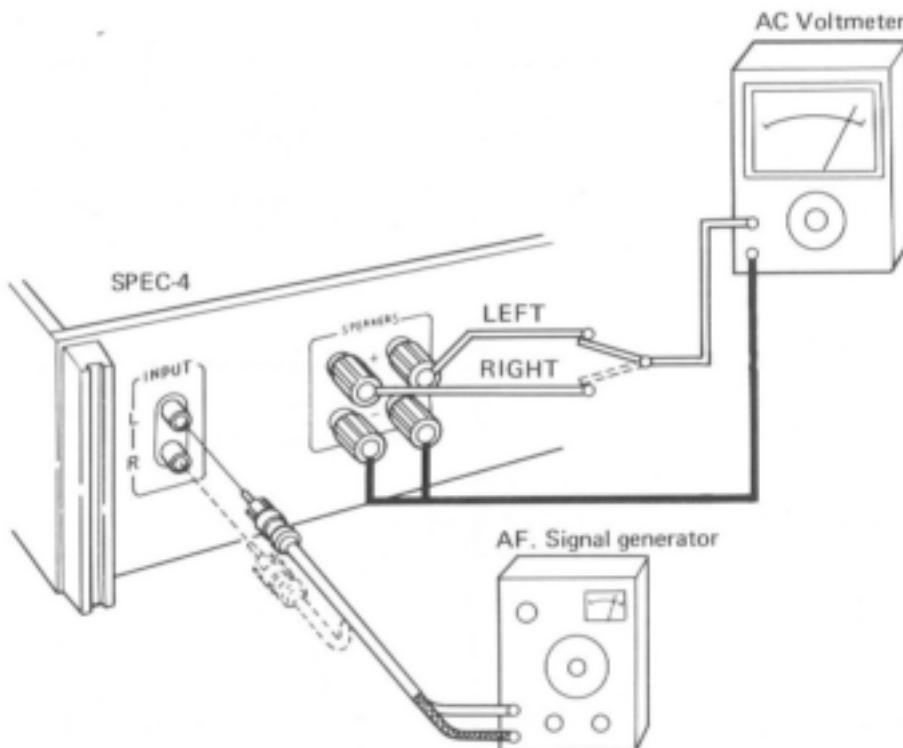

Fig. 13 Connection diagram for meter amplifier adjustment
