5M21/5M20
SERVICE MANUAL

SM21/SM20 Alignment Procedure

The SM21 and the SM20 are of DC amplifier configuration unlike conventional AC amplifiers. Therefore, the following items should be noted in case of the alignment procedure. Don't think the same procedure as that for the AC amplifier can be followed.

- (1) To apply AC mains power source with loads connected will cause blow-off of power transistors if connections or wirings are imperfectly soldered. Therefore, check all the wirings to printed circuit boards before turning on the AC mains power.
- (2) This power amplifier amplifies even DC. Slight DC ingredients are often present in old testing equipments or in DC amplified ones. In case such DC voltage is fed to the amplifier, the DC is amplified enough to give damage to the amplifier. Therefore, set the "INPUT CAPACITOR" switch provided at the back panel to the "IN" position before operating the amplifier.
- (3) $\pm 60V - \pm 70V$ DC voltage is applied at the final stage amplifier board, the driver stage board and the constant voltage board. Especially at the "B" power supply, giant electrolytic capacitors are employed, and it takes a long time to finish discharging. When you proceed to disconnect printed circuit board, do it after perfect discharge by use of a resistor or an electric bulb.
- (4) The power transistors' section at the final stage is driven in class "AB" operation, which is different from our conventional amplifiers driven purely in class "B" operation. Therefore, check the idling current as soon as possible after turning the power switch on, to protect power transistors from breakage by excessive current.
- (5) Our original FET hybrid I.C. (Dual Monolithic Linear I.C.) is used in the pre-driver stage. This I.C. contains differential stage, constant current circuit and cascode circuit. Check if the pins of the I.C. are correctly and perfectly connected before turning the AC mains power on.
- (6) The output terminals for Peak Indicator are provided in this amplifier. These are taken from the Speaker Terminals through 1k ohm resistor, therefore it might be possible that the resistor burns out or the amplifier itself is damaged, in case short-pins etc. are mistakenly inserted to these terminals to cause short-circuit. Note that these are not input terminals.

Position of knobs before alignment

- (1) Attenuator Volume: MIN.
- (2) Speaker Terminals: Connect oscilloscope and milivoltmeter. Do not connect loads.
- (3) AC Mains Switch, Meter Sensitivity Selector Switch: OFF
- (4) Input Capacitor Switch: ON

Position of knobs at the time of delivery

- (1) Attenuator Volume: MAX.
- (2) Input Capacitor Switch: ON
- (3) AC Mains Switch, Meter Sensitivity Selector Switch: OFF

- (1) Connect a DC ammeter to power board PB-1080 for Idling Current Alignment.
- (2) Connect AC cord to the output of variable transformer, then slowly increase AC voltage to confirm gradual movement of the ammeter.
- (3) Set the AC voltage to the rated AC mains voltage.
- (4) Adjust the Bias VR to obtain 150mA idling current.
- (5) Check the output voltage of PB-1082 (power supply for driver) to be $+68V \pm 10\%$ DC.
(This can be done at the print terminal on PB-1079.)
- (6) Adjust trimmer potentiometer on the driver board to obtain 0V DC output voltage.
- (7) Check if the normal voltage is obtained at the Speaker Protection Circuit, the DC Offset Circuit and the Meter Circuit respectively. (Check the voltage listed on the circuit diagram.)
- (8) Check if the Stand-by lamp blinks.
By depressing the power switch, the LED for the Stand-by lamp begins blinking, then muting for speaker relay and relay for meter are turned on after 3 - 15 seconds, and when the blinking stops the pilot lamp lights on.
(Note: with the 5M20, only the pilot lamp light up.)
- (9) Adjust the trimmer potentiometer on the driver board again to obtain 140mA idling current.
This alignment should be done 5 minutes after finishing step 4.
- (10) Check the voltage at the output terminal to be 0V DC. If shifted, readjust it. This also should be done 5 minutes after finishing step 6.
- (11) Set the voltage of variable transformer down to 0V. Wind and solder plated wire around the print terminals for adjustment of idling current.
- (12) Gradually increase voltage of variable transformer up to 80% of the rated AC mains voltage, where power relay starts to operate. Set AC voltage to the rated AC mains voltage.
- (13) Turn off the power switch.
- (14) Both of Speaker Muting Relay and Meter Relay (DC Offset Relay for the 5M20) break at the same time.
- (15) Turn on the power switch. (AC voltage at the rated AC mains voltage.)
- (16) Confirm the Stand-by lamp begins blinking, and 3 - 15 seconds later the muting-relay and the meter-relay are turned on to switch on the pilot lamp.
- (17) Apply 1kHz sine-wave to the amplifier, and check the output voltage comes out smoothly up to 29V.
- (18) Apply 1kHz sine-wave, and check the attenuator volume operates normally.

Alignment of Main Amp Section

- (1) Turn off the power switch.
- (2) Connect 8-ohm load-resistor to the output terminal.
- (3) Set AC power supply to the rated AC mains voltage, and turn on the power switch.
- (4) After finishing the muting-period, gradually apply 10kHz sine-wave signal. Set the attenuator to MAX. Hereafter, the attenuator should be in the "MAX." position unless otherwise specified. Operation shall be with "both channels driven".

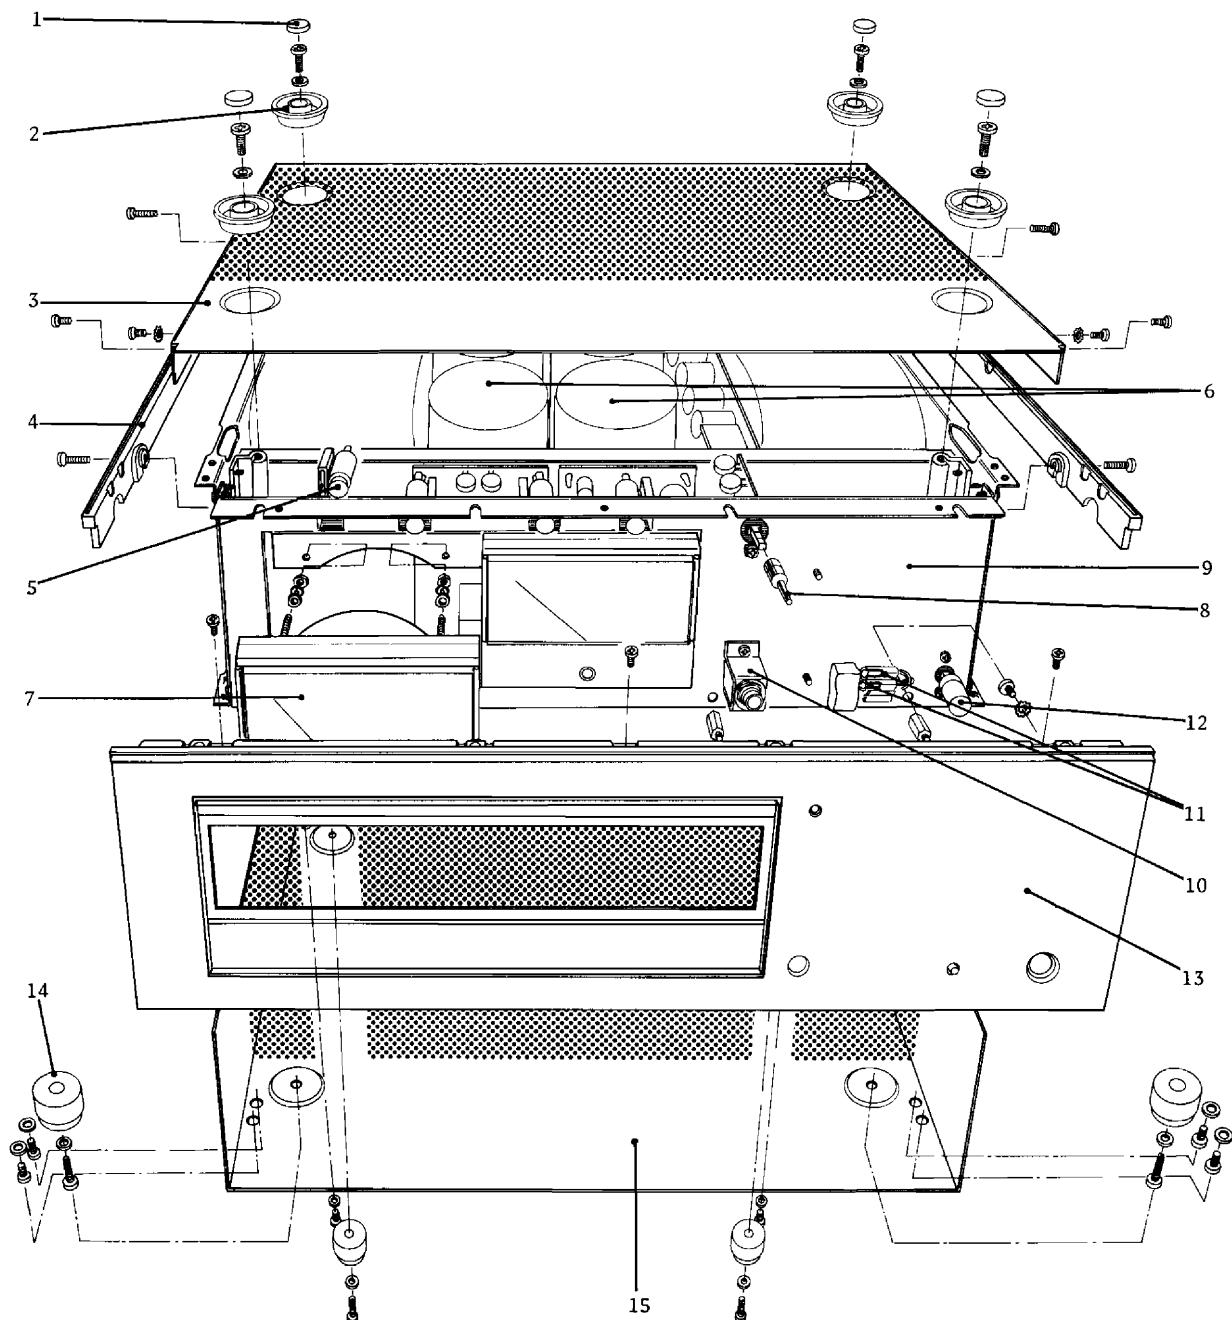

- (5) Distortion should be no more than 0.005% at 1kHz with 28.3V load-voltage.
- (6) At this time the input voltage should be $0.89V \pm 10\%$.
- (7) Then apply 20Hz and 20kHz sine-wave, and check the distortion is no more than 0.008% with 28.3V load-voltage.
- (8) Distortion should be no more than 0.008% at 20kHz with 20V load-voltage.
- (9) Distortion should be no more than 0.008% at 30kHz with 20V load-voltage.
- (10) Crosstalk should be no more than -70dB at 10kHz. At this time, the channel with no input signal should be short-circuited at the input terminals.
- (11) Short-circuit at the input pin-jack of both channels, and check if the noise level is no more than 0.1mV. At the same time, confirm the wave-form does not contain large amount of 'spike' or 'pulse' products. Also the noise level at the time of input-open (vol; MAX, MIN) should not be larger than that under other conditions.
- (12) When a headphone is inserted to the headphone jack, check if signals are switched to the headphone from the speaker terminals. At the same time, check L-ch and R-ch.

Protection Circuit

- (1) When 5Hz sine-wave is applied to the input of amplifier and as the output of oscillator increases, the DC drift sensing circuit operates in the vicinity of 22 - 29V output to shut off the speaker relay (into STAND-BY condition), or it repeats ON-OFF operation.
Load; 8 ohms Attenuator; Max.
- (2) DC Offset Test
Confirm the pilot lamp turns from blue to red in case DC voltage of $20mV \pm 5mV$ is applied to the input terminal, or in case $500mV \pm 200mV$ voltage appears at the output terminal.
Note that only when DC voltage is fed to the input terminal, the pilot lamp turns back to blue in 2 or 3 seconds after setting the Input Capacitor Switch to "ON" (which shows the DC offset is recovered.)
- (3) Check the muting relay breaks when DC 3 - 5V appears at the output terminal.

Meter Circuit

- (1) Adjust the trimmer potentiometer on PB-1085 to obtain 0dB indication on the meter, when 1kHz sine-wave is applied to the input of the amplifier and the output voltage is set to 28.3V.
- (2) Set the output voltage to 8.9V for the model whose meter sensitivity is -10dB, while set it to 2.83V for the -20dB model.
- (3) Adjust trimmer potentiometer on PB-1083 to obtain 0dB reading on the meter. Repeat steps (2) (3).
(It is advisable to connect attenuator outside.)
- (4) When the Meter Sensitivity Selector Switch is turned on, applying 10Hz and 10kHz sine-waves with 8.9V load-voltage for the -10dB model, while 2.83V for the -20dB model, frequency response should be within $\pm 1dB$ and mutual deviation should be within 0.5dB.

SP0037	Push Switch (power)
UB1027	Sub Panel
WZ1038	LRS Lamp Holder 1038

REAR-PANEL UNIT

STOCK NO.	DESCRIPTION
AG0073	AC socket MD-40
AH0001	Fuse Holder S-N1301
AT0013	2P Pin Jack
AT0065	SP Terminal T-5572
RD0026	Resistor 22k
RD0354	Resistor 1k 1/2W
RV0140	VR 50k-B(15KC)
UC1047	Back Panel 1047

SPECIFICATIONS**[5M21]**

Power Output:	100W minimum continuous per channel into 8-ohm loads, both channels driven at any frequency from 10Hz to 20,000Hz with no more than 0.008% total harmonic distortion
Rated I.M.:	no more than 0.008% (8-ohm, 60 : 7KHz = 4 : 1)
Frequency Response:	DC~100,000Hz (-1dB)
Input Sensitivity:	890mV
Input Impedance:	50k ohms
Signal to Noise Ratio:	120dB (IHF A-curve, input short-circuit)
Residual Noise:	no more than 0.1mV (input short-circuit)
Crosstalk:	no more than -100dB (100Hz) no more than -70dB (20 - 20kHz)
Damping Factor:	80 (8-ohm, 1kHz)
Other Features:	VU meter for left & right channels, Meter sensitivity selector switch (0dB, -10dB) Input capacitor IN/OUT switch Audio attenuator for both channels Connection terminal for Peak indicator Extra AC outlet (unswitched)
Protection Circuits:	DC offset senser, DC-drift sensing circuit, Abnormal temperature sensing circuit, Excessive current protection circuit
Semiconductors:	DML-IC (2), transistors (49), Diodes (43)
Power Consumption:	450W (8-ohm, at maximum output)
Dimensions:	442(W) x 400(D) x 146(H) mm (17-13/32 x 15-3/4 x 5-3/4")
Weight:	Net 19kgs (41.8 lbs.) Gross 21kgs (46.2 lbs.)
