1. INTRODUCTION

This service manual was prepared for use by Authorized Warranty Stations and contains service information for Marantz Model 120 Stereophonic Tuner.

Servicing information and voltage data included in this manual are intended for use by the knowledgeable and experienced technician only. All instructions should be read carefully. No attempt should be made to proceed without a good understanding of the operation in the tuner.

The part lists furnish information by which replacement parts may be ordered from the Marantz Company. A simple description is included for parts which can be usually obtained through local suppliers.

2. AM TUNER

The AM Tuner section of this model is identical with that of Marantz's new integrated Tuner/Amplifier Model 2270. All components except Tuning capacitor and ferrite bar antenna are mounted on a printed circuit board P150.

The AM signals induced in a ferrite bar antenna are applied to the base of RF amplifier transistor H151 through a capacitor of C151 and amplified to the level required for overcomming the conversion noises, thus giving good S/N performance.

Thus amplified and selected AM signal is then applied to the base of converter transistor H152 through a coupling capacitor C156. The local oscillator voltage is injected to the emitter of H152 through a capacitor C157. Both AM signal and oscillating voltage are mixed at the base-emitter junction of the converter transistor and converted into a 455 KHz intermediate frequency. The resulting IF signal is then applied to the first IF transformer L153 consisting of one ceramic filter and two tuned circuits. The output of the L153 is led to the H153 which in turn apply its output to the transistor of next stage H154. Thus fully amplified IF signal is then applied to the diode H157 through the detector transformer L154 and detected. The detected signal is then filtered and amplified, thus obtained final audio output is applied to the TAPE OUT jacks and the function push switch.

The DC component of the detected IF signal is used as a AGC voltage to control the emitter current of H153 which in turn controls the bias current of the RF amplifier through the resistors R179 and R151.

A part of IF signal output is also applied to the diodes H158 and H160 through a capacitor C167 and rectified to obtain DC voltage for driving the vertical amplifier of the scope display circuit.

2.1 Suggestions for AM Tuner Trouble Shooting

Symptom: No reception

Check for broken AM bar antenna, next try to tune station by rotating fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether it deflects up and down or not. If the spot moves up and down as you tune past each station, no failure may exist in the stages at least preceding final IF transformer L154. Next connect a high sensitive oscilloscope to the pin terminal J162 or J157 and check for the detected audio signals with the tuner correctly tuned to a station. If the spot does not moves up and down when you tune past each station, check the local oscillator circuit. Normal oscillating voltage at the hot end of the oscillator tuning capacitor is about 2 to 3 volts, depending upon the tuning capacitor position. When measuring oscillating voltage use a RF VTVM, no circuit tester gives correct readings. If the local oscillator voltage is normal, check all voltage distributions in the AM circuits by using a DC VTVM and compare the measured values with those given in the schematic diagram.

3. FM TUNER

3.1 RF and IF Circuit

The FM Tuner section of the Model 120 is divided into five functional blocks: FM Front End, IF Amplifier, Detector, Muting Control, and MPX Stereo Decoding Circuit.

FM signals induced by a FM antenna are led to FM antenna coil L101 through an attenuator switch and a Balun coil. These signals are then applied to the FET RF amplifier which in turn applies its output to the next FET Mixer H102 through the triple tuned high selective circuits. The FET Mixer converts its input signal into 10.7 MHz intermediate frequency and amplifies it at the same time. The H103 is a local oscillator and its output is injected into the source of the FET Mixer, the injection voltage is about 700mV. The 10.7 MHz front end output is led to the next IF amplifier unit through a coaxial cable.

The IF amplifier unit consists of six stages of IF amplifier and one stage of AGC amplifier. Eight pieces of ceramic filters are also used to obtain high selectivity, three stages of symmetrical diode limiters are also employed for the best limiting characteristics, improved capture ratio and AM good suppression.

A part of FM Front End output is applied to the AGC amplifier H207 and rectified its output is fed back to the gate of FET RF amplifier to decrease the gain with increased signal strength.

The signals required for multipath indication are obtained from the three stages of IF amplifiers through coupling capacitors C234, C236 and C238 respectively and rectified by three pair of full wave diode circuits. Thus obtained three AM components in the FM signal are appropriately mixed and applied to the vertical amplifier for multipath display.

The IF signal sufficiently amplified through each stage of IF amplifier is finally applied to the IC limiter on the Detector Unit. The detected audio output is led to the buffer amplifier H502 and its buffered output is led to; (a) noise amplifier H551 through resistor R551 and capacitor C551, (b) Quad Radial Jack on the rear panel through resistor R563, (c) MPX stereo decoding circuit through R563.

3.2 Audio Muting and Stereo mode auto-selecting circuit

The muting circuit consisting of all solid-state electrical switching has been incorporated in the Model 120. Three inputs control the muting function. The first is related to signal strength, the second to the noise condition at the detector and the third is derived from the DC component of the detector output. These inputs are properly matrixed and gated to provide muting free from noise and transients.

The first input of DC voltage obtained by rectifying a part of IF output signal from the H206 is applied to the base of H306 and turns on it, if the IF output is greater than predetermined level (muting threshold level). When the H306 is turned on the H307 is turned off, allowing the emitter-collector resistance increasing and the collector voltage rises about 9.7V. The increased collector voltage increases the gate bias voltage and turns on the switching FET H308, decreasing the sourcedrain resistance to near zero ohm and allowing the audio signal applied to the source to flow to the center of 38 KHz switching transformer through the source-drain path.

When the input signal is lower than predetermined level, the DC output obtained is small and can not make the H306 turn on, thus the H306 keeps its turn-off state and this makes H307 turn on, decreasing the collector voltage and turning off H308. Thus no audio signals can pass through the FET. This is the fundamental principle of the muting operation but for more elaborate muting operation the second and the third inputs are necessary.

The second input is used to protect the muting operation and MPX stereo beacon lamps from misoperation due to undesirable noises. The high frequency noises included in the detected audio signals are separated by a small capacitor C551 and amplified by the noise amplifier transistor H551 and its output is rectified by the two diodes. The rectified DC output is proportional to the noise components in the audio signals.

When there are excessive noises in the audio signals such as obtained with a station uncorrectly tuned in, the rectified DC output turns on the transistor H522, decreasing the emitter-collector resistance to zero. This means the collector of H307 is short-circuited to the ground, therefore the H308 is turned off and any audio signals having excessive high frequency noises can not go through the FET's source-drain path.

The transistor H303 connected in series with the 19 KHz pilot signal amplifier transistor H302 is also turned off (when the transistor H522 or H307 are turned on.) and no current flows in the H302, resulting in turning off the stereo beacon lamps.

Thus misoperation due to undesirable noises is also avoided.

The third input is obtained from the FM discriminator circuit.

The DC output so called "S" curve is applied to the gate of H558 through a resistor R523 and dividing network (R565 & R566). The DC output is zero with a station correctly tuned in, but will vary from negative to positive values or vice versa when a station is tuned past from right to left or vice versa.

When the DC output is increased to a greater level than that predetermined, the increased source potential of H558 makes the H560 turn on and the H306 is turned off. The subsequent changes are exactly the same as those just described above.

Thus when the tuning is shifted or deviated to the certain frequencies in which undesirable noisy side-audio signals are produced, both muting and 19 KHz switching transistors are automatically operated and open the circuits.

With the station correctly tuned in, the bias current of the FET H558 is adjusted so that both transistor H560 and H561 are not turned on, giving no effect on the transistor H306.

3.3 MPX Stereo Decoding Circuit

The buffered and non-equalized audio signals are applied to the first amplifier H301 which serve as a tuned amplifier for the pilot signal in the composite signals and as a buffer amplifier for the audio signals. The amplified 19 KHz pilot signal is led to the second 19 KHz amplifier H302 and further amplified if switching transistor H303 is turned on by the DC controlling signal as described in the preceding chapter. The final 19 KHz pilot signal is rectified by the doubler circuit consisting of the H315 and H316 to obtain synchronized 38 KHz driving signal.

The H304 is the 38 KHz tuned amplifier and supplies its output to the switching matrix circuit consisting of four diodes. While the composite signals are applied to the center tap of switching transformer 1/2 L302. The right and left stereo signals decoded by the switching circuit are led to the crosstalk cancelling amplifier which utilizes complementary configuration with NPN and PNP transistors through de-emphasiss networks consisting of C315 and R335, and C316 and R336. L305 is a low-pass filter networks having very sharp cut off characteristics and eliminates undesirable residual switching signals. Transistors H313 and H314 are buffer amplifiers and their outputs are led to FM push switch.

3.4 Suggestion for Trouble Shooting of FM Tuner

3.4.1 Symptom: No FM Reception

Turn on the POWER switch.

Turn on (depress) two scope display switches "ON" and "TUNING".

First try to tune to some FM stations.

Rotate the fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether it follows an approximately rectangular path as you tune past each station or not. If it moves as described, the tuner circuits preceding the discriminator circuit may have no failure. If not, there would be some defects in the front end or IF amplifier stages, or oscilloscope circuits. To localize the defects in the former case, check FM local oscillator circuit, using RF VTVM. The normal local oscillator voltage is one or two volts (rms) at the tuning capacitor, depending on the tuning capacitor position. If the local oscillator voltage is normal, next check all voltage

distribution in the front end and IF amplifier stages and compare them with those shown in the circuit diagram.

For localizing the defects in the latter case it is one of methods to apply a audio signal to the external audio jacks on the rear panel with the "EXTERNAL" scope display switch depressed.

The detected audio signals can also be checked by depressing the scope display switch "AUDIO" if scope circuit operate without any defects.

3.4.2 Symptom: No Stereo Separations

First check the "MONO" switch is in normal out position.

Connect a FM RF signal generator output modulated by a stereo modulator to the rear FM antenna terminals, and check the stereo beacon is turned on or not. If not turned on, check for 19 KHz pilot signal and 38 KHz switching signal, using an oscilloscope.

4. SCOPE DISPLAY CIRCUIT

Please, refer to the operating manual on general operating instructions for "SCOPE DISPLAY".

4.1 AM Tuning Display

AM signal strength and the correct tuning point are displayed on the scope through the following signal routine:

Rectified DC output at pin terminal J159 → R709 (330K ohm) → R708 (180K ohm) → AM push switch → TUNING push switch → EXTERNAL push switch → scope ON switch → Pin terminal J802 → J906 → H902 vertical amplifier

Note: C703 and C702 are filtering capacitors.

4.2 FM Tuning Display

FM signal strength and correct center tuning signals are applied to the oscilloscope's vertical and horizontal deflection plates through the following routines;

- a. Rectified DC output for FM signal strength at the pin terminal J208 → R559 (trimming resistor) → AM push switch TUNING push switch → EXTERNAL push switch → SCOPE ON push switch → R802 (270K ohm) → pin terminal J802 → J906 → Vertical amplifier (for signal strength)
- b. DC plus and minus output for center tuning at the pin terminal J504 → R809 → TUNING push switch → EXTERNAL push switch → scope ON push switch → R801 → Pin terminal J801 → J905 → Horizontal Amplifier (for center tuning)

Note 1. C804 and C805 are filtering capacitors for audio singnals.

Note 2. For easy-to-see spot display, the display spot is modulated to have a slight length in vertical direction for FM tuning or in horizontal direction for AM tuning. This is done by applying a small amount of AC voltage for pilot lamps to the vertical (for FM) or Horizontal (for AM) amplifier input terminal J902 or J901 respectively.

AC voltage for pilot lamps → R803 → C803 → TUNING push switch → AM push switch → J902 (for FM) or J901 (for AM)

* R852 is the DC bias adjusting resistor which corrects the spot position at no signal.

4.3 FM MULTI-PATH DISPLAY

The multi-path display circuit is almost the same as the FM TUNING DISPLAY circuit except the following:

- a. AC voltage for tuning spot modulation is cut off (R803 and C803 are disconnected) from the circuit by depressing the MULTI-PATH push switch.
- b. Audio signal pass filter (C804 & C805) are also cut off, this means audio signals developed at J504 are applied to the horizontal amplifier.

The vertical signal which contains multi-path information is the same as that of signal strength and supplied to the R559 through the pin terminal J208.

5. SCOPE CIRCUIT DESCRIPTION

5.1 Vertical Amplifier

The vertical amplifier consists of two stages of direct-coupled differential amplifiers, the first stage using two FETs (H902 and H912) and the second two transistors (H904 and H906). This amplifiers signals of from DC to AC frequency with very stability. The over-all gain is 46 dB for DC and 49 dB for AC signals (including attenuator network consisting of R802 and R902).

The vertical signal selected by a function push switch and led to the scope display switch is applied to the input circuit of the FET differential amplifier through the attenuator net work (R802 and R902). The fist differential amplifier operates as a source follower and no voltage gain is obtained. The signal passed the first stage is directly fed to the second stage and amplified. The gain of this stage is 56 dB for DC signals and 59 dB for AC signals. The finally amplified signal is then applied to the oscilloscope tube.

- * R918 is a DC gain adjusting resistor and should be set for the gain of 290mV/cm.
- * The AC gain has been set about 3 dB higher than DC gain by a RC network consisting of R912, C907 and C905.
- * R930 is provided for adjusting DC balance between H902 and H912 and should be set so that the voltage difference between the source terminals of H902 and H912 is less than 0.05 volt with two centering control knobs placed in their mechanical center.

5.2 Horizontal Amplifier

The circuitry of horizontal amplifier is almost the same as that of the vertical amplifier.

- * R917 is DC gain adjusting resistor and should be set for 400mV/cm.
- * The AC gain has been adjusted 5 dB higher than DC gain by the RC network consisting of R911, C906 and C904.
- * R929 is the DC balance control between H901 and H911 and should set so that the voltage difference between source terminals of H901 and H911 is less than 0.05 volt with two centering control knobs placed in their mechanical center.

6. POWER SUPPLY CIRCUIT

- a. Power source for tuner (+13.5V) and stereo beacon (12.5V) is zener-regulated and then filtered by a transistor ripple filter circuit consisting of H405.
- b. Power source for MPX Pre-Amp (+35V) and Pre-Amp (+36V) is fed through a transistor ripple filter circuit consisting of H406.
- c. Both DC plus and minus 13.5V for the first differential amplifiers are zener-regulated by two zener diodes, H003 and H410, respectively.
- d. DC +200V for collector circuits of the vertical and horizontal amplifies and DC -500V for CRT's anode are fed by the power supply circuit.

7. TROUBLE SHOOTING OF OSCILLOSCOPE CIRCUIT

7.1 Symptom: No spot obtained

If no spot is obtained with centering knobs (V and H) placed in their mechanical center and BRIGHTNESS control on the rear panel at maximum, there would be defects in the CRT's circuit, vertical and/or horizontal amplifier. To localize the defects proceed as follows:

- a. Short both collector terminals of H904 and H906, and if the spot appear the vertical amplifier would be defective.
- b. Short both collector terminals of H903 and H905, and if the spot appear the horizontal amplifier would be defective.
- c. If no spot is still obtained, the CRT circuit would be defective.

7.2 Symptom: Blurred spot

First adjust FOCUS control on the rear panel and if no sharp spot is obtained, check whether the voltage between cathode of CRT (No. 3 terminal) and plate (No. 4 terminal) can be varied from 150V to 250V or not by adjusting FOCUS control on the rear panel. If the voltage varies within the limit above, the oscilloscope circuit is normal. Please, try to replace the CRT with new one.

CAUTION

1. Do not leave the scope turned ON with brightness control set maximum.

Do not make the spot left for a long time with its brightness maximum and its focus pin-pointed to avoid possible desensitivity of the phosphor. In the case where the scope has to be turned for a long time decrease the brightness of the spot. Turn the scope off when not in use.

2. High Voltage, Danger

When removing the top and/or bottom cover, always remove the power cord from the AC outlet to avoid possible electrical shock from high voltage for oscilloscope circuit.

3. Do not place the set (CRT) in a powerful magnetic field.

If placed, the electron beam in the CRT will be bent and the spot is shifted from the correct position. The trace may also be distorted.

8. SCOPE DISPLAY ALIGNMENT

8.1 Depress both scope display switches "ON" and "EXTERNAL".

8.2 Adjust two centering knobs to bring the spot into the center of small circular.

8.3 Adjust "BRIGHT" control (R007) on the rear panel to make the brightness of the spot dimmer.

8.4 Adjust "FOCUS" control (R006) to make the spot smaller and more circular.

8.5 Feed in DC 290mV to the "SCOPE INPUT, HORIZ" jack and adjust R917 (HORIZ) to obtain a horizontal deflection of about 2cm, then connect the same DC input voltage to the "VERT" jack and adjust R918 (VERT) for the same vertical deflection.

8.6 Set both the centering knobs at their mechanical center, and adjust R929 (HORIZ) and R930 (VERT) to bring the spot into the center of small circular.

9. TUNING DISPLAY ALIGNMENT

9.1 Depress both scope display switches "ON" and "TUNING" and mode selection switch "AM".

9.2 Adjust R854 to bring the spot on the lower center of the base line with no station tuned in.

10. FM TUNING DISPLAY ALIGNMENT

10.1 Depress both scope display switches "ON" and "TUNING" and mode selection switch "FM".

10.2 Connect FM signal input of 100 K μ V (98 MHz, 400 Hz, 30% Mod.) to the FM ANT terminal and adjust R559 so that the spot does not frame out.

10.3 FM Multipath display alignment: Adjust R809 to obtain full deflection of the trace within both side marks, applying FM signal (1 K μ V, 400 Hz 100% Mod.) to the FM antenna terminals.

10.4 Connect FM signal (98 MHz, 400 Hz 100% Mod, 1 K μ V) to the antenna terminals and tune the same frequency, then rotate the tuning knob slowly and adjust R917 so that maximum deflection of the spot moving toward left or right direction does not frame out.

11. AM ALIGNMENT

AM IF Alignment:

- 11.1 Connect a sweep generator to the J151 and an alignment scope to the J162.
- 11.2 Rotate each core of IF transformer L153 and L154 for maximum height and flat top symmetrical response.
- 11.3 Set AM signal generator to 525 KHz. Turn the tuning capacitor fully closed (place the tuning pointer at the low end.) and adjust the oscillator coil L152 for maximum audio output.
- 11.4 Set the signal generator to 1650 KHz. Place the tuning pointer in the high frequency end and adjust the oscillator trimmer on the oscillator tuning capacitor for maximum audio output.
- 11.5 Repeat the step 1 and 2 until no further adjustment is necessary.
- 11.6 Set the generator to 600 KHz and tune the receiver to the same frequency and adjust a slug core of AM ferrite rod antenna and RF coil L151 for maximum output.
- 11.7 Set the generator to 1400 KHz and tune the receiver to the same frequency and adjust both trimming capacitors of Antenna and RF tuned circuit for maximum output.
- 11.8 Repeat the step 4 and 5 until no further adjustment is necessary.

Note: During tracking alignment reduce the signal generator output as necessary to avoid AGC action.

12 FM ALIGNMENT

- 12.1 Connect a FM signal generator to the FM antenna terminals and a oscilloscope and an audio distortion analyzer to the tape output jacks on the rear panel.
- 12.2 Set the FM SG to 87.5 MHz and provide about 3 to 5 μ V. Place the tuning pointer at the low frequency end by rotating the tuning knob and adjust the core of oscillator coil L105 to obtain maximum audio output.
- 12.3 Set the FM SG to 108.5 MHz and provide about 3 to 5 μ V output. Rotate the tuning knob and place the tuning pointer at the high frequency end and adjust the trimming capacitor C106 for maximum output.
- 12.4 Repeat the step 2 and 3 until no further adjustment is necessary.
- 12.5 Set the FM SG to 90 MHz and tune the receiver to the same frequency. Decrease singal generator output until the audio output level decreases with the decreasing generator output. Adjust the antenna coil L101, RF coil L102, L103 and L104 and IF transformer L106 for minimum audio distortion.
- 12.6 Set the FM SG to 106 MHz and tune the receiver to the same frequency. Adjust the trimming capacitor C102, C103, C104 and C105 for minimum distortion.
- 12.7 Connect a VTVM (with DC 1 V range) across the pin terminal J504 and common ground. Adjust the secondary core (black) of discriminator transformer L501 so that the VTVM indicates null reading (zero reading) at no signal. Set the FM SG to 98 MHz and increase its output level to 1 KK μ V and tune the receiver to the same frequency so that the VTVM gives null reading. Next adjust the primary core (pink) of L501 for minimum distortion. (Scope display can, of course, be used as tuning indicator instead of the VTVM, if the scope unit has been correctly adjusted as instructed in the SCOPE DISPLAY ALIGNMENT.)

13. STEREO SEPARATION ALIGNMENT

- 13.1 Set the FM SG to provide 1 K μ V at 90 MHz. Tune the receiver to the same frequency so that The VTVM (see 12.7) indicates null reading.
- 13.2 Modulate the FM SG with stereo composite signal consisting of only subchannel signal (pilot signal must be included). Adjust the core of L301 for maximum audio output, then modulate the FM signal generator with a stereo comosite signal consisting of only L channel

signal and again adjust the core of L301 for maximum audio output.

13.3 Adjust the trimming resistor R365 for maximum and same separation in both channels.

14. MUTING CIRCUIT ALIGNMENT

14.1 Connect a VTVM across the resistor R853 and adjust the resistor R853 until the meter reads 0.75V DC at no signal.

14.2 Set the FM SG to provide 1 K μ V at 98 MHz and tune the receiver to the same frequency correctly.

14.3 Turn on MUTING push switch. Shift the FM signal generator frequency to plus and minus and note both plus and minus shifted frequencies at which undesirable audio side responses are muted out. Adjust the R853 so that each shifted frequency range becomes equal.

15. VOLTAGE CONVERSION

This model is equipped with a universal power transformer to permit operation at 100, 120, 200, 220 and 240V AC 50 to 60 Hz.

To convert the Model 2270 to the required voltage perform the following steps:

- (1) Remove the top cover.
- (2) Remove the Transformer Wire Connection Terminal Cover, loosen two Cover mounting screws on the rear panel, see Fig. 1.
- (3) Change the jumper wires as illustrated in Fig. 2, for the required AC voltage and replace the fuse as instructed.

CAUTION: DISCONNECT POWER SUPPLY CORD FROM AC OUTLET BEFORE CONVERTING VOLTAGE.

16. TEST EQUIPMENT REQUIRED FOR SERVICING

Table 1 lists the test equipment required for servicing the Model 120 Tuner.

Item	Manufacturer and Model No.	Use
AM Signal Generator		Signal source for AM alignment
Test Loop		Used with AM Signal generator
FM Signal Generator	Less than 0.3% distortion	Signal source for FM alignment
Stereo Modulator	Less than 0.3% distortion	Stereo separation alignment and trouble shooting
Audio Oscillator	Weston Model CVO-100P, less than 0.02% residual distortion is required.	Sinewave and squarewave signal source.
Oscilloscope	High sensitivity with DC horizontal and vertical amplifiers.	Waveform analysis and trouble shooting, and ASO alignment.
VTVM	With AC, DC, RF range	Voltage measurements.
Circuit Tester		Trouble Shooting

SPECIFICATIONS

FM SECTION

Tuning Frequency Range	88 MHz–108 MHz
IHF Usable Sensitivity	2.3 μ V
IHF Selectivity	80 dB
Capture Ratio	1.6 dB
Image Rejection Ratio at 106 MHz	93 dB
Signal to Noise Ratio in Mono	70 dB
Signal to Noise Ratio in Stereo	60 dB
Total Harmonic Distortion in Mono	0.15%
Total Harmonic Distortion in Stereo	0.3%
Frequency Response (ref. 75 μ sec. de-emphasis)	\pm 1 dB (50 to 15 KHz)
Stereo Separation	42 dB at 1 KHz 26 dB at 10 KHz 36 dB at 200 Hz

AM SECTION

Tuning Frequency Range	540 KHz–1605 KHz
Usable Sensitivity20 μ V
Selectivity	26 dB
Image Rejection Ratio at 1400 KHz	70 dB
Signal to Noise Ratio	46 dB
Frequency Response, –3 dB down	50 Hz–4 KHz
Total Harmonic Distortion	1%

OSCILLOSCOPE SECTION—EXTERNAL INPUT

1. Vertical Amplifier

Deflection Sensitivity	DC 290mV/cm, AC 65mV/cm
Input Impedance	420 K ohm
Input Capacitance	Less than 30 pF
Maximum Permissible Input Voltage	100V P-P (AC or DC)

2. Horizontal Amplifier

Deflection Sensitivity	DC 400mV/cm, AC 65mV/cm
Input Impedance	420 K ohm
Input Capacitance	Less than 30 pF
Maximum Permissible Input Voltage	100V P-P (AC or DC)

GENERAL

Power Requirements	100/120/200/220/240V AC 50 Hz to 60 Hz 40 Watts
------------------------------	---

Dimensions

Panel Width	15.4 Inches
Panel Height	5.8 Inches
Depth	11.8 Inches

Weight

Unit Alone	21 lbs
Packed for Shipment	29.3 lbs

* These specifications and exterior designs may be changed for improvement without advance notice.

MODEL 120 SERVICE MANUAL

This Service Manual is the first revised edition for model 120 (Applied to production serial No. from 1001 to 1510).

Included in this service manual are schematic diagram, individual parts list and P.C. Board-Component Assembly Diagram.

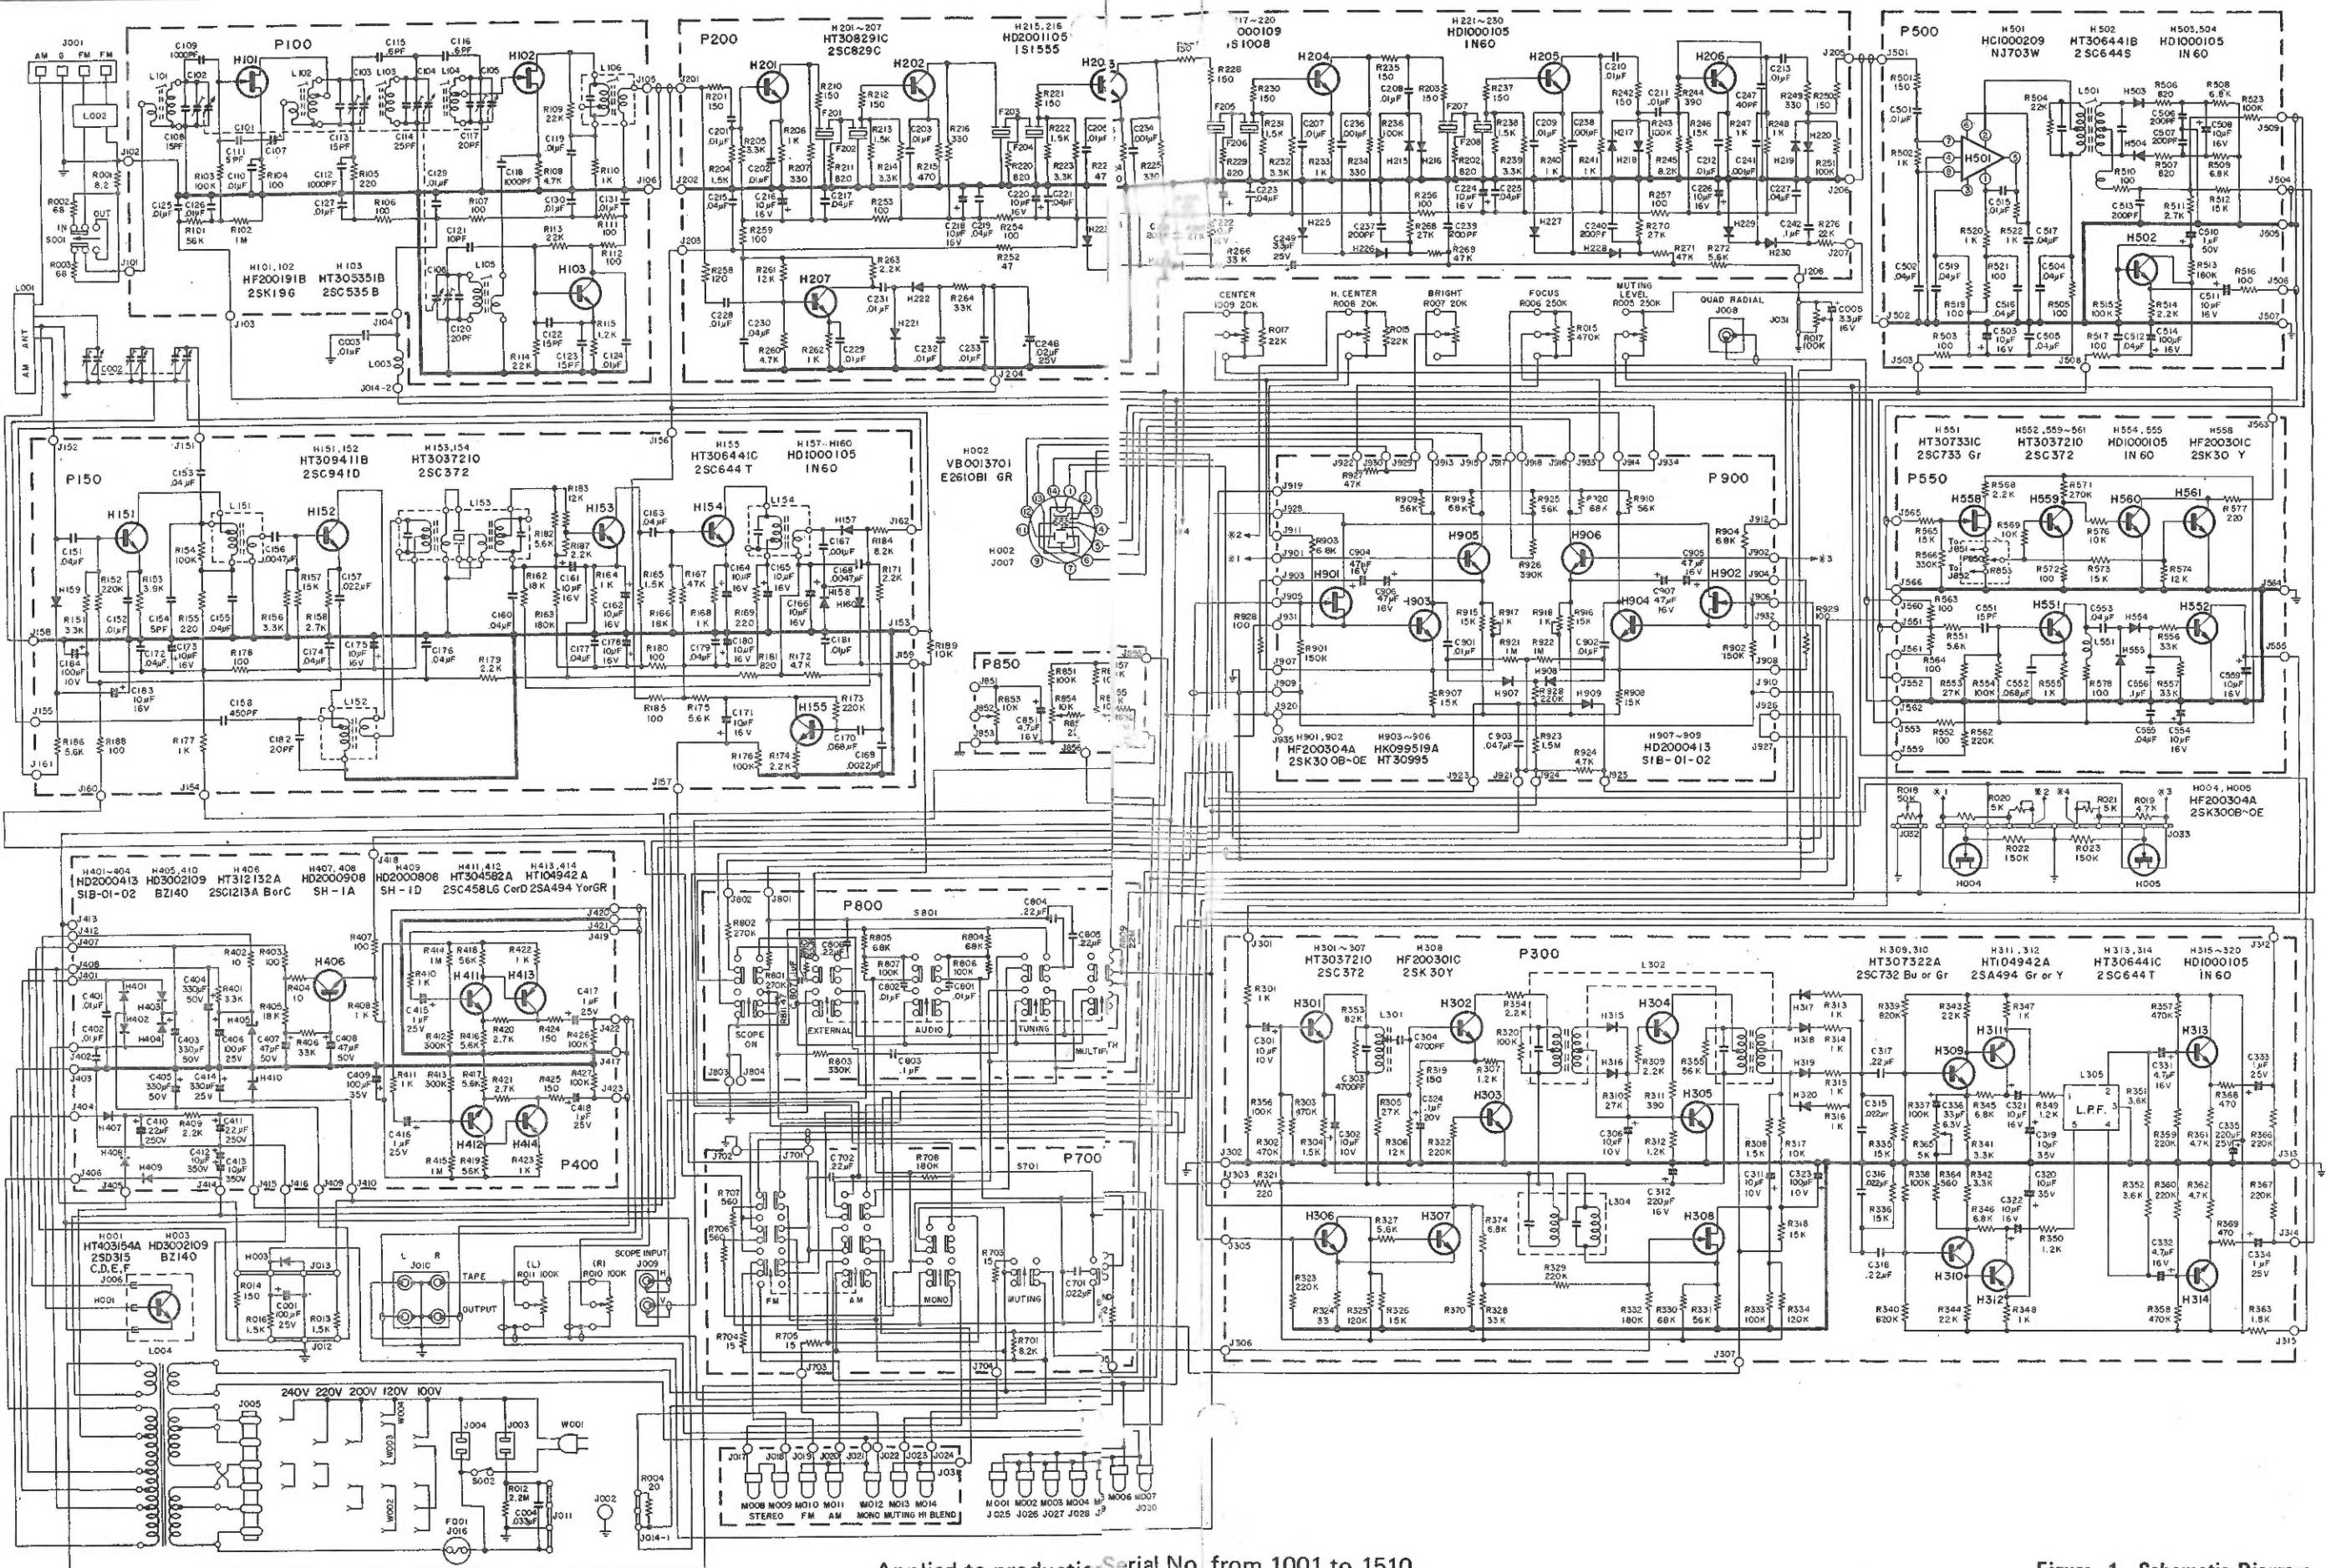

[Redacted description area]

TABLE OF CONTENTS

Parts List	1
Schematic Diagram	3
P.C. Board-Component Assembly Diagram	5
