INSTRUCTIONS FOR INSTALLATION AND OPERATION

Model Nos. 21-22-522 and 81 Series

This receiver employs a chassis of latest design. The frequency range covered is 540-1750 kilocycles.

TUBES (Model 21 series)
6D6, 6C6, 38, 76
(Model 81 & 22 and 522 series)
6D6, 6C6, 38, 76, K90F

ANTENNA The antenna built into the set will perform to give best results in most localities. However, in communities located more than 100 miles away from a broadcasting station, an outside antenna of 50 to 75 feet may be necessary for better performance. This antenna should be attached to the end of the built in antenna hank.

VOLUME CONTROL AND ON/OFF SWITCH This control is located on the lower right side of the receiver. To place set in operation, turn this knob to the right. This automatically turns the receiver on. To decrease volume to desired level, turn this control to the left. To turn set off, rotate the control to the extreme left until click is heard.

SELECTOR KNOB The selector knob is located on the upper right hand side of the receiver. It is used to tune in desired stations. The scale is calibrated in kilocycles.

INSTALLATION a. Unhank the line cord and stretch it out to its full length before connecting to the 105-125 volts, 50-60 cycles AC or DC power lines. Under this condition, the cord will feel warm. THIS IS NORMAL. Operating with the cord hanked or rolled up may cause it to heat excessively and damage set. DO NOT CUT THIS CORD TO SHORTEN OR LENGTHEN IT.

b. When using DC current, allow the receiver to warm up for 60 seconds. IF AFTER THAT TIME RECEIVER DOES NOT FUNCTION, REVERSE THE PLUG IN THE ELECTRIC OUTLET.

c. CAUTION — Do Not Connect Ground Wire to Chassis.

ALIGNMENT

INTERMEDIATE FREQUENCY - Connect the Signal Generator to grid of 6A7 tube through a .05 MFD condenser. Ground Generator to Ground of chassis. Set Generator at 456 KC and adjust trimmers on IF transformers for Max. Peak.

BROADCAST BAND - Connect the Generator to the antenna of receiver through a 1000MFD condenser. Ground Generator to ground of chassis. Range switch in Broadcast position. Set Generator to 1400 KC and adjust Oscillator and RF trimmers to maximum peak. Dial of receiver set on 1400 KC. Pad the Broadcast band at 600 KC, rocking gang condenser during the adjustment.

SHORT WAVE BAND - Set Receiver and Generator to 6000 KC. Range switch in SW position. Adjust SW antenna trimmer for maximum peak. No padding adjustment is required on this band.

C14 - 50 K

ALIGNMENT

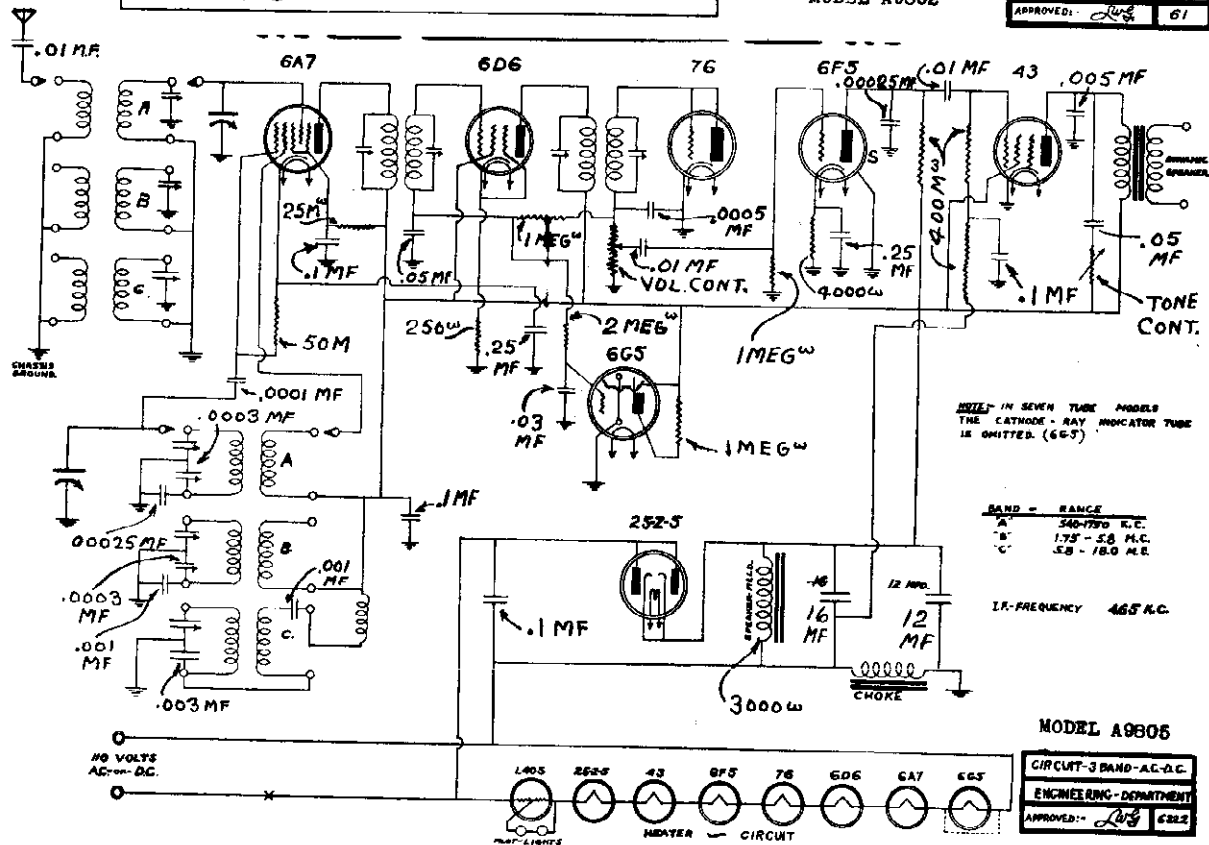

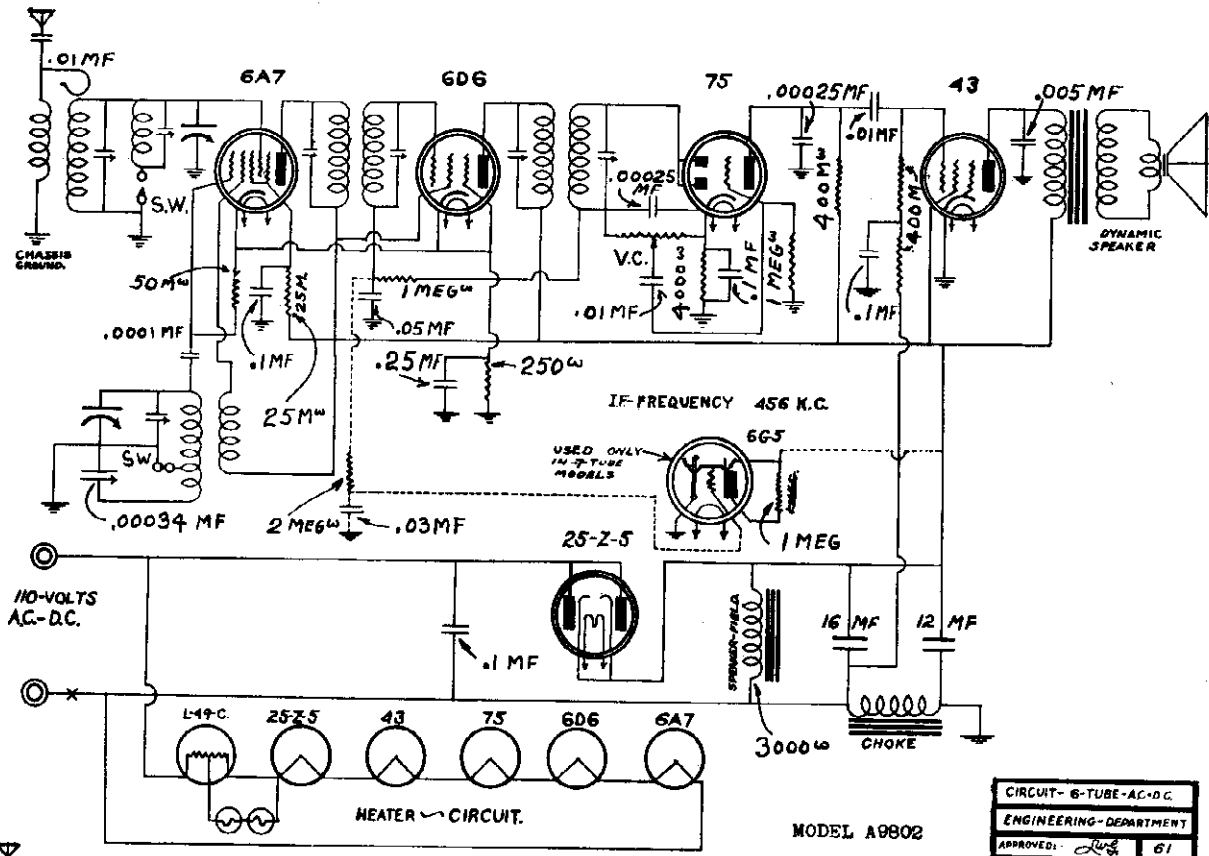

I.F. ALIGNMENT. Adjust the test oscillator to 175 K.C. and connect the output directly to the grid of the first detector tube (6A7), without the use of any series condenser or resistor; the omission of series condenser and resistor to block out the AVC action. The ground on the test oscillator can be connected to the chassis ground. Align the trimmers of the first and second I.F. transformers to peak or maximum reading on the output meter.

OSCILLATOR ALIGNMENT. Adjust the test oscillator to 1400 K.C. and connect the output to the antenna through a .0001 mfd. mica condenser to give the equivalent of a low capacity type average auto antenna. Set the dial pointer to 1400 K.C. and adjust the oscillator trimmer to peak. (Front section of gang condenser.)

R.F. ALIGNMENT. The next step is to adjust the center and rear trimmers of the gang condenser to peak. The center section of the gang condenser tunes the antenna amplifier stage (6D6 tube), and the rear condenser section tunes the detector grid coil of the 6A7 tube.

2ND I.F. TRIMMERS BROADCAST PADDING CONDENSER ON & OFF SWITCH & VOLUME CONTROL (UPPER) TUNING KNOB (LOWER)

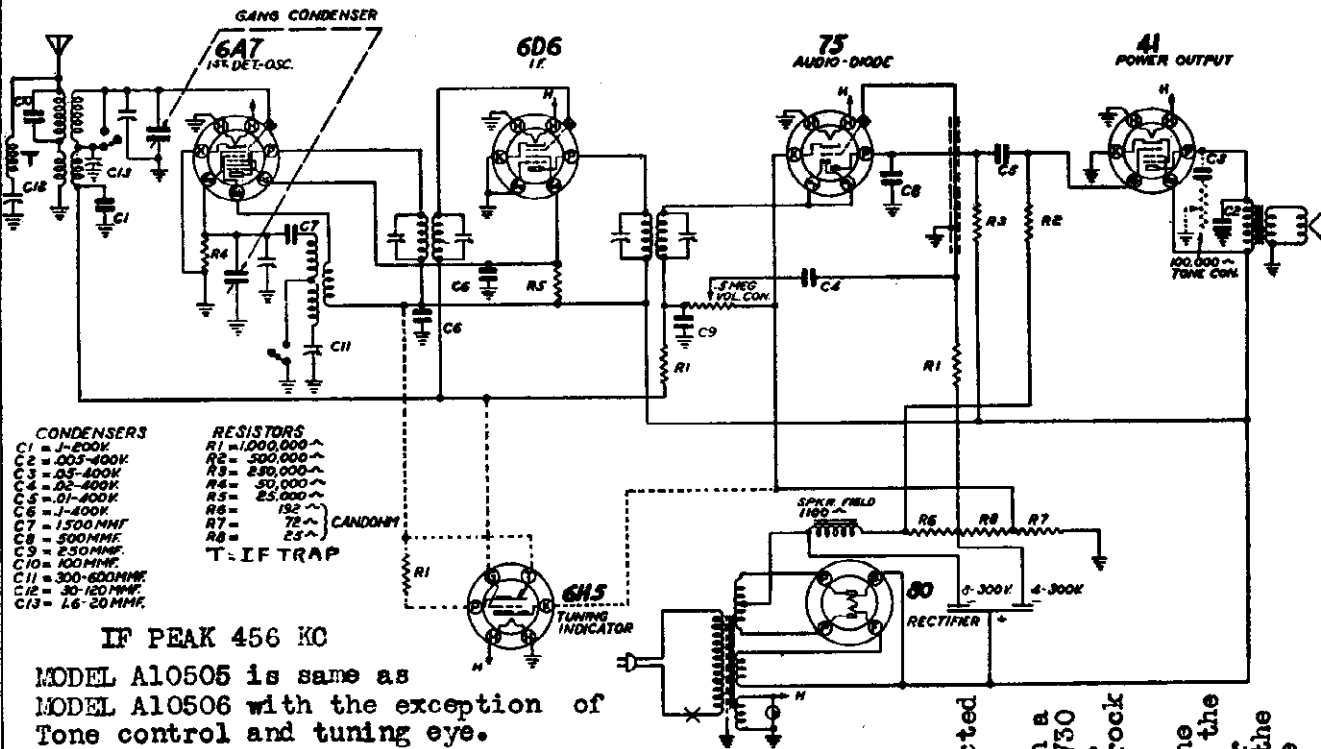

IF ALIGNMENT - Wave switch on B.C. position. Generator connected to grid of 6A7 through a .05 IFD condenser. Align four trimmers.

BROADCAST - Connect generator to antenna lead through a 100 MFD condenser. Gang condenser at minimum. Generator set at 1730 KC and adjust oscillator trimmer to peak. Set generator at 1400 KC, adjust Antenna trimmer to peak. Generator and receiver set at 600 KC, rock gang condenser while padding oscillator to maximum peak.

SHORT WAVE - Generator set to 6000 KC, while rotating gang condenser from the high frequency end of dial until the generator signal is heard, adjust the S.W. antenna trimmer for maximum peak. Be sure to align this trimmer on the first signal heard while rotating gang condenser from high frequency end. Repeat adjustments for maximum performance of the receiver.

Alignment, Notes

ANDREA RADIO CORP.

otherwise proceed with step 3 and 4.

Set the signal generator to 17,000 K.C. and the receiver dial pointer to 17 M.C. (17,000 K.C.). Adjust oscillator shunt trimmer slowly between maximum and minimum. A signal will be heard at two settings of this trimmer; one near the minimum capacity (plates open) of the trimmer, the other nearer to maximum capacity (plates closed). The trimmer should be left adjusted to the signal heard near its minimum (open plates). The adjustment nearer maximum is the image frequency setting, as can be determined from previous explanation on page 8-5.

3. Align R.F. shunt trimmer for maximum output deflection. During this adjustment, be certain to rotate the station selector knob back and forth slowly for each small R.F. shunt trimmer change. During this adjustment, be certain to rotate the station selector knob back and forth slowly for each small antenna shunt trimmer change until maximum output is obtained. Retrim R.F. shunt trimmer for small change. Check to see that alignment has not been made on the image. (See notes).

Set test generator to 6000 K.C., retune receiver until signal is heard. Adjust oscillator series trimmer slowly while rotating the gang condenser around the signal for each small adjustment of the series trimmer until further adjustment of the series trimmer decreases the output signal.

Never touch the ANT., R.F. and OSC. shunt trimmer during this adjustment. Reset test generator to 17,000 K.C.; tune receiver until correct signal is heard. Retune antenna and R.F. shunt trimmer for final critical setting. During this final adjustment, never touch the oscillator shunt trimmers. Individual coils can be checked very simply as follows:

Apply the test generator signal through a .1 mfd. coil to the 6AG3 grid, and carry out the procedure outlined above. This will tell you if the oscillator shunt trimmer only is correctly adjusted or the right signal setting has been used on the test generator. In this case, ONLY, the image and fundamental will have the sure intensity.

When you are sure the oscillator circuit is correct, place the signal on the grid of the 6K7S R.F. tube, and repeat the procedure on the R.F. coil. In this case when correctly aligned, the image will be lower in volume than the fundamental.

Replace the .1 mfd. condenser in the test generator lead with a 400 ohm resistor and repeat procedure on antenna.

This method now assures you of correct individual alignment on each coil. Then proceed to touch up each coil except the oscillator as outlined.

LONG WAVE BAND "L" ALIGNMENT (This band is included in the D7L chassis only)

1. Set signal generator for 175 K.C. and connect generator high potential lead in series with .1 mfd. condenser to grid of 6AG3 tube.
2. Set receiver dial to 175 K.C. (1714 meters).
3. Adjust L.W. series oscillator trimmer until the loudest signal is heard. This point is required because of the wide frequency range the L.W. series oscillator trimmer has on the oscillator frequency. Due to this wide change in frequency it is possible that several different adjustment points in the L.W. series oscillator trimmer will produce output signals, but only one of these is correct (the loudest).
4. Set the generator and receiver dial to 400 K.C. (750 meters) and adjust L.W. oscillator shunt trimmer until the signal is heard.
5. After readjusting the L.W. oscillator shunt trimmer it is very important that the generator and dial be set for 175 K.C. (1714 meters) and the L.W. series oscillator trimmer readjusted as given in paragraph 3. Set the generator and receiver dials back to 400 K.C. (750 meters) with the oscillator shunt trimmer until the signal is heard.
6. Remove generator and connect to antenna of receiver. .00025 mfd. condenser and connect to 400 K.C. (750 meters).
7. Set generator and receiver dial to 400 K.C. (750 meters).
8. Adjust antenna and R.F. shunt trimmer for maximum output deflection.
9. Change generator and dial to 175 K.C. (1714 meters). Adjust L.W. series oscillator trimmer for maximum deflection. (Be certain to rotate gang condenser for each adjustment of the series trimmer).
10. Repeat adjustments set forth in paragraph 8 or receiver will not be aligned correctly because of effect given in paragraph 3.
11. After carrying out 10 be sure to repeat 8.
12. Both 8 and 9 must be repeated until it is noticed that the trimmers no longer improve alignment. The receiver is then correctly aligned.

When aligning the "S" band at 17,000 K.C., any adjustment of the antenna shunt and R.F. shunt trimmer will affect the oscillator tuning. This must be compensated for during the alignment, but rotating the gang condenser slowly back and forth about the signal for each shunt trimmer adjustment, until maximum deflection on the output meter is obtained. If the gang condenser is not rotated, false alignment and poor receiver sensitivity will result.

When receiver is incorporated in a 1.0 volt bias cell in the grid circuit of the 75 tube (see circuit diagram), THIS CELL MUST NEVER BE SHORTED OR TESTED BY MEANS OF A LOW RESISTANCE 2000 OHM PER VOLT VOLTMETER. THE ONLY ACCURATE WAY TO MEASURE ITS POTENTIAL IS BY MEANS OF A VACUUM TUBE VOLTMETER. These cells can be expected to render at least three years service without replacement. If further data is required, write the manufacturer.

FUNDAMENTAL & IMAGE FREQUENCY NOTES

A simple method of checking to determine if the receiver and generator are tuned for correct alignment is as follows:

Set the signal generator to 17,000 K.C. Tune the receiver from 15,000 K.C. to 18,000 K.C. Two signals should be heard 940 K.C. apart on the receiver, namely, one lower in frequency than 17,000 K.C., the other higher. The correct point for alignment is the higher frequency on the receiver dial. The lower is the image. As a check, the receiver should be left tuned to the higher frequency. Increase the generator frequency which was set for 17,000 K.C. slowly to approximately 18,000 K.C. A signal should be heard near 18,000 K.C. If the first setting was correct for alignment, no signal would indicate that the original setting was on the image frequency. If this occurs, make certain that you start from the beginning to be sure of your results, make after the correct setting has been found, and the alignment has been carried out, it will be noted that the image or lower frequency responses on the receiver dial will always sound weaker than the true signal if the tuned circuits have been correctly adjusted.

470 K.C. I.F. ADJUSTMENT

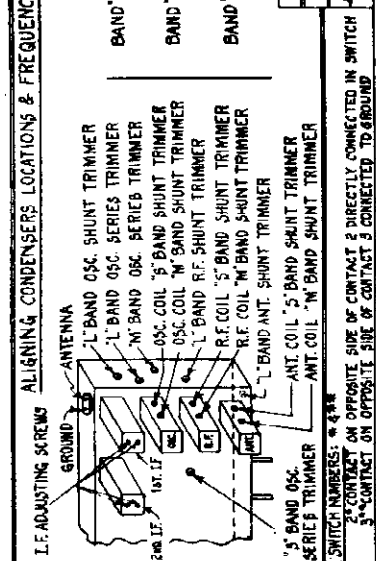

1. Connect high potential output lead from test generator in series with a .1 mfd. condenser to the grid of the 6AG3 with selector switch in "M" band position and dial at 1000 K.C. NEVER REMOVE CONTROL GRID CAP FROM TUBE.
2. Connect output voltmeter (copper oxide rectifier type) across voice coil of speaker.
3. Set generator to supply a modulated 470 K.C. signal. Adjust generator output attenuator until a small output reading is obtained on the output voltmeter.
4. Adjust both trimmers on top of the first and second I.F. transformers for maximum output.
5. Retrim slightly the first I.F. trimmer.

MEDIUM BAND "M" ALIGNMENT

1. Set test generator for 1400 K.C. Connect high potential lead of test generator in series with a .1 mfd. condenser to grid of 6AG3 tube. Tune receiver to 1400 K.C. (214.3 meters) on the tuning scale. If signal is not heard, leave scale pointer set to 1400 K.C. (214.3 meters), and adjust oscillator coil shunt trimmer slowly and carefully until signal is heard. The oscillator coil of the receiver and dial are now set correctly, assuming the test generator calibration is correct.
2. Remove test generator hot lead from 6AG3 grid. Replace .1 mfd. condenser with 250 mfd. (.00025 mfd.) and connect to antenna terminal of receiver "A", all other settings to remain the same.
3. Adjust "R.F." coil shunt trimmer and then "ANT" coil shunt trimmer for maximum output deflection.
4. Retune test generator to 600 K.C. (500 meters) and tune receiver to 600 K.C. (500 meters) until signal is heard.
5. Adjust oscillator coil series trimmer slowly while rotating the gang condenser slowly about the signal for each small adjustment of the series trimmer, until further adjustment of the series trimmer does not increase the output signal. During this adjustment, never touch the ANT., R.F. or OSC. shunt trimmers.
6. Reset test generator and receiver to 1400 K.C. Tune in signal on receiver. Adjust ANT. and R.F. shunt trimmers slightly for maximum output; never the OSC. shunt trimmer.

SHORT WAVE "S" BAND ALIGNMENT

1. Turn wave band selector switch to extreme right "S" band. Replace 250 mfd. (.00025 mfd.) condenser with 400 ohm resistor.
2. The following adjustment is necessary if the dial calibration is badly off;

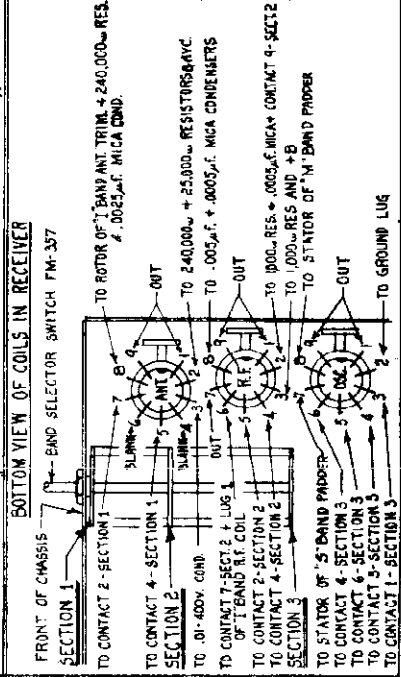

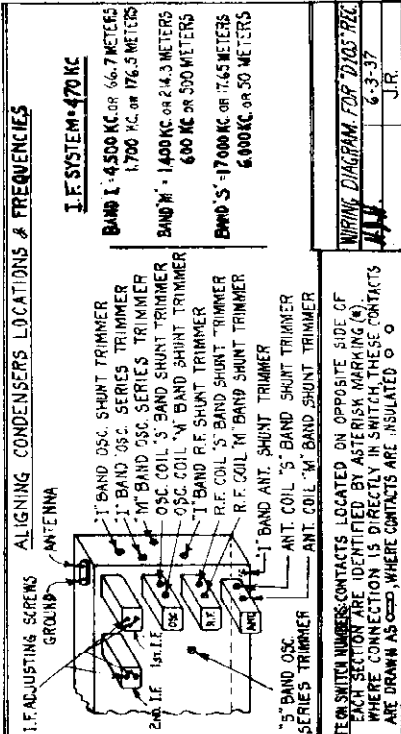

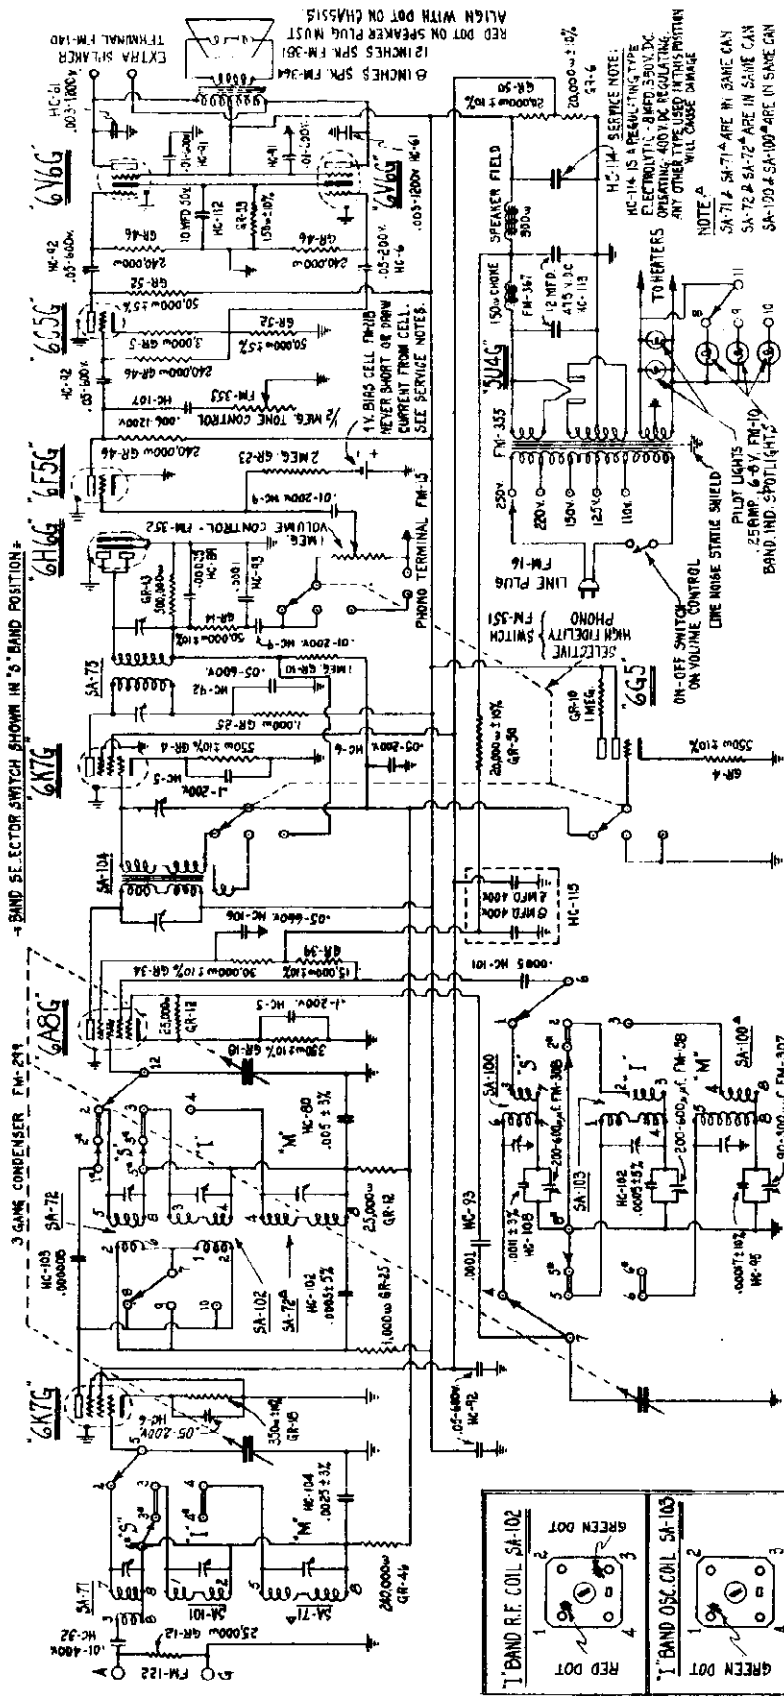

MODELS 2D10, 4D10, 6D10, 8D10, 10D10

Chassis D10S

8D10, 10D10
Chassis D10S
Alignment**

Just oscillator series trimmer slowly while rotating the gang condenser around the signal for each small adjustment of the series trimmer until no further adjustment of the series trimmer increases the output signal.
NEVER TOUCH THE ANT., R.F. AND OSC. SHUNT TRIMMER DURING THIS ADJUSTMENT.
Reset test generator to 17,000 K.C.; tune receiver until correct signal is heard. Remove antenna and R.F. shunt trimmer for final critical setting. During this final adjustment, never touch the oscillator shunt trimmers.

THE "S" BAND IS NOW ALIGNED.

Should the operator be inexperienced on "S" band alignment, the individual coils can be checked very simply as follows:
Apply the test generator signal through a .1 mfd. coil to the 6AG5 grid, and carry out the procedure outlined above. This will tell you if the oscillator shunt trimmer only is correctly adjusted or the right signal setting has been used on the test generator. In this case, ONLY, the image and fundamental will have the same intensity.
When you are sure the oscillator circuit is correct, place the signal on the grid of the 6AV6 R.F. tube, and repeat the procedure on the R.F. coil. In this case when correctly aligned, the image will be lower in volume than the fundamental.
Replace the .1 mfd. condenser in the test generator lead with a 400 ohm resistor and connect to antenna terminal "A", and repeat procedure on antenna. This method now assures you of correct individual alignment on each coil.
Then proceed to touch up each coil except the oscillator as outlined in 3 and 4.

LONG WAVE BAND "L" ALIGNMENT

- THIS BAND IS INCLUDED IN THE D10L CHASSIS ONLY.**
TURN THE WAVE BAND SELECTOR SWITCH TO THE "L" POSITION.
1. Set signal generator for 175 K.C. and connect generator high potential lead in series with .1 mfd. condenser to grid of 6AG5 tube.
2. Set receiver dial to 175 K.C. (1714 meters).
3. Adjust L.W. series oscillator trimmer until the loudest signal is heard. This point is required because of the wide frequency range the L.W. series oscillator trimmer has on the oscillator frequency. Due to this wide change in frequency it is possible that several different adjustment points in the L.W. oscillator series trimmer will produce output signals, but only one of these is correct (the loudest).
4. Set the generator and receiver dial to 400 K.C. (750 meters) and adjust L.W. oscillator shunt trimmer until the signal is heard.
5. After readjusting the L.W. oscillator shunt trimmer it is very important that the generator and the set dial be set for 175 K.C. (1714 meters) and the L.W. series oscillator shunt trimmer set to 400 K.C. (750 meters) as in paragraph 3. Set the generator dial to 400 K.C. (750 meters) and adjust L.W. oscillator shunt trimmer until the signal is heard.
6. Remove generator lead from grid of 6AG5. Replace .1 mfd. condenser with .00025 mfd. condenser and connect to antenna of receiver.
7. Set generator and receiver dial to 400 K.C. (750 meters).
8. Adjust antenna and R.F. shunt trimmer for maximum output deflection.
9. Change generator and dial to 175 K.C. (1714 meters). Adjust L.W. series oscillator trimmer for maximum deflection. (BE CERTAIN TO ROTATE GANG CONDENSER FOR EACH ADJUSTMENT OF THE SERIES TRIMMER).
10. Repeat adjustments set forth in paragraph 8 or receiver will not be aligned correctly because of effect given in paragraph 3.
11. After carrying out 10 be sure to repeat it.
12. Both 8 and 9 must be repeated until it is noticed that the trimmers no longer improve alignment.
INTERMEDIATE WAVE BAND "I" ALIGNMENT

THIS BAND IS INCLUDED IN THE D10S CHASSIS ONLY.

- TURN THE WAVE BAND SELECTOR SWITCH TO THE "I" BAND POSITION.**
1. In series with the generator high potential output lead connect a .00025 mfd. (.250 mf.) condenser and connect to antenna "A" terminal of the chassis.
2. Tune generator and receiver to 4500 K.C. - 4.5 megacycles.
3. If signal is not heard leave scale pointer set to 4.5 megacycles and adjust oscillator "I" band shunt trimmer slowly and carefully until the signal is heard. The oscillator coil and dial are now correctly aligned and require no further adjustment.
4. Adjust R.F. coil shunt trimmer and then the ANT. for maximum output deflection.
5. Reset generator and receiver to 1700 K.C. (1.7 megacycles). Pick up signal with receiver on either side of 1.7 megacycles.
6. Adjust "I" band oscillator series trimmer only while turning the gang condenser. Being careful not to touch antenna and forth about the signal for each small adjustment of the series trimmer.
Continue this until no further adjustment of the series trimmer produces an increase in the output deflection.
Return generator and receiver to 4500 K.C. (4.5 megacycles). Tune in signal on receiver. Readjust ANT. and R.F. shunt trimmers slightly for any small change.

FUNDAMENTAL & IMAGE FREQUENCY NOTES

A simple method of checking to determine if the receiver and generator are tuned for correct alignment is as follows:
Set the signal generator to 17,000 K.C. Tune the receiver from 15,000 slowly up to 18,000 K.C. Two signals should be heard 940 K.C. apart on the receiver, namely one lower in frequency than 17,000 K.C. the other higher. The correct point for alignment is the higher frequency on the receiver dial, whichever is the image. As a check, the receiver should be left tuned to the higher frequency on the generator frequency which was set for 17,000 K.C. slowly and carefully to 18,000 K.C. A signal should be heard near 18,000 K.C. if the original setting was on the image frequency. If a signal would indicate that the original setting was on the image frequency, the signal would indicate certain that you start from the beginning to be sure of your results, make after the correct setting has been found, and the alignment has been carried out, it will be noted that the image or lower frequency response on the receiver dial will always sound weaker than the true signal if the tuned circuits have been correctly adjusted.
470 K.C. I.F. ADJUSTMENT

- CAUTION:** The I.F. system must always be aligned with the SELECTIVE-EL-FI-PRONO in the SELECTIVE POSITION or insensitivity or poor selectivity will result.
1. Connect high potential output lead from test generator in series with a .1 mfd. condenser to the grid of the 6AG5 with selector switch in "M" band position and dial to 1000 K.C. NEVER REMOVE CONTROL GRID CAP FROM TUBE.
2. Connect output voltmeter (copper oxide rectifier type) across voice coil of speaker.
3. Set generator to supply a modulated 470 K.C. signal. Adjust generator output until a small output reading is obtained on the output voltmeter.
4. Adjust both knobs of the first and second I.F. transformers for maximum output (SEE CHECK THE SWITCH IS ON THE SELECTIVE POSITION).
5. Retain slightly the first I.F. adjustment.

MEDIUM BAND "M" ALIGNMENT

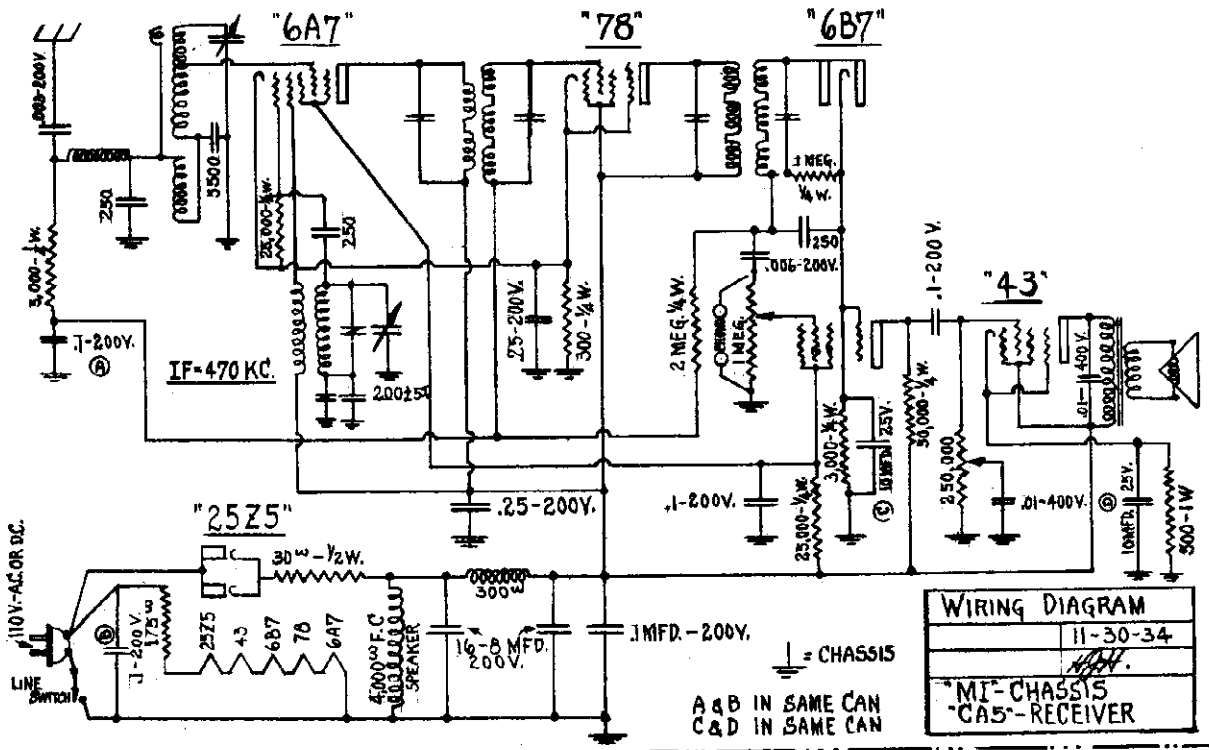

TURN THE WAVE BAND SELECTOR SWITCH TO THE "M" POSITION.
Set test generator for 1400 K.C. Connect high potential lead of test generator in series with a .1 mfd. condenser to grid of 6AG5 tube. Tune receiver to 1400 K.C. (214.3 meters) on the tuning scale. If signal is not heard, leave scale pointer set to 1400 K.C. (214.3 meters), and adjust oscillator coil shunt trimmer slowly and carefully until signal is heard.
The oscillator coil of the receiver and dial are now set correctly, assuming the test generator calibration is correct.
Remove test generator but lead from 6AG5 grid. Replace .1 mfd. condenser with 250 mf. (.00025 mfd.) and connect to antenna terminal of receiver "A", all other settings to remain the same.
Adjust R.F. coil shunt trimmer and then "ANT" coil shunt trimmer for maximum output deflection.
Remove test generator but lead from 6AG5 grid. Replace .1 mfd. condenser with 500 mf. (.00050 mfd.) and tune receiver to 600 K.C.
Adjust oscillator coil shunt trimmer slowly while rotating the gang condenser slowly about the signal for each small adjustment of the series trimmer until further adjustment of the series trimmer does not increase the output signal. During this adjustment, never touch the ANT., R.F. or Osc. shunt trimmers.
Reset test generator and receiver to 1400 K.C. Tune in signal on receiver. Adjust ANT. and R.F. shunt trimmers slightly for maximum output. NEVER THE OSC. SHUNT TRIMMER.

SHORT WAVE "S" BAND ALIGNMENT

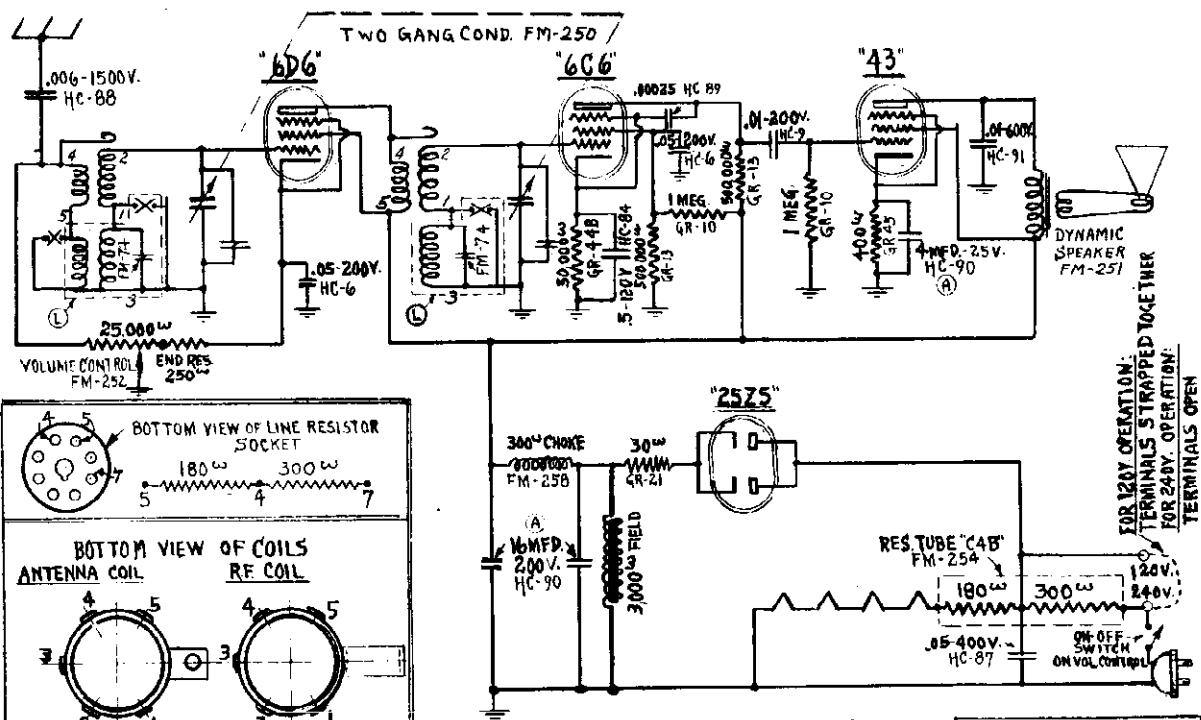

1. Turn wave band selector switch to extreme right "S" band. Replace 250 mf. (.00025 mfd.) condenser with 400 ohm resistor.
2. Off setting adjustment is necessary only if the dial calibration is badly off other than paragraph 4.
3. Set the signal generator to 17,000 K.C. and the receiver dial pointer to 17 M.C. (17,000 K.C.). Adjust oscillator shunt trimmer slowly between maximum and minimum. A signal will be heard at two settings of this trimmer; one near the minimum capacity (plates open) of the trimmer, the other nearer to maximum capacity (plates closed). The trimmer should be left adjusted to the signal heard near its minimum (open plates). The adjustment nearer maximum is the image frequency setting, as can be determined from previous explanation on image frequency.
4. Align R.F. shunt trimmer for maximum output deflection. During this adjustment, be certain to rotate the station selector knob back and forth slowly for each small R.F. shunt trimmer change.
5. Align antenna shunt trimmer for maximum output deflection. During this adjustment, be certain to rotate the station knob back and forth slowly for each small antenna shunt trimmer change until maximum output is obtained on the image. (See notes). Check to see that alignment has not been made on the image. (See notes).
Set test generator to 6000 K.C., return receiver until signal is heard. Ad-

Alignment, Trimmers

of the series trimmer, until further adjustment of the series trimmer does not increase the output signal. During this adjustment, never touch the ANT., R.F. or OSC. shunt trimmers.

Reset test generator and receiver to 1400 K.C. Tune in signal on receiver. Adjust Antenna and R.F. shunt trimmers slightly for maximum output - NEVER THE OSC. SHUNT TRIMMER.

SHORT WAVE "S" BAND ALIGNMENT

1. Turn wave band selector switch to extreme right "S" band. Replace 250 mfd. (.00025 mfd.) condenser with 400 ohm resistor.
2. The following adjustment is necessary only if the dial calibration is badly off, otherwise proceed with steps 3 and 4.

Set the signal generator to 15,000 K.C. and the receiver dial pointer to 15 K.C. (15,000 K.C.). Adjust oscillator shunt trimmer slowly between maximum and minimum. A signal will be heard at two settings of this trimmer, one near the minimum capacity (plates open) of the trimmer, the other nearer to maximum capacity (plates closed). The trimmer should be left adjusted to the signal heard near its minimum (open plates). The adjustment nearer maximum is the image frequency setting, as can be determined from previous explanation on Image Frequency.

3. Align R.F. shunt trimmer for maximum output deflection. During this adjustment, be certain to rotate the station selector knob back and forth slowly for each small R.F. shunt trimmer change.
4. Align antenna shunt trimmer for maximum output deflection. During this adjustment, be certain to rotate the station knob back and forth slowly for each small antenna shunt trimmer change until maximum output is obtained. Retrim R.F. shunt trimmer for any small change. Check to see that alignment has not been made on the image. (See notes)

Set test generator to 6000 K.C. Return receiver until signal is heard. Adjust oscillator series trimmer slowly while rotating the gang condenser around the signal for each small adjustment of the series trimmer until no further adjustment of the series trimmer increases the output signal.

NEVER TOUCH THE ANT., R.F. OR OSC. SHUNT TRIMMERS DURING THIS ADJUSTMENT.

Reset test generator to 15,000 K.C. Tune receiver until correct signal is heard. Return antenna and R.F. shunt trimmer for final critical setting. During this final adjustment, never touch the oscillator shunt trimmer.

THE "S" BAND IS NOW ALIGNED.

Should the operator be inexperienced on "S" band alignment, the individual coils can be checked very simply as follows:

Apply the test generator signal through a .1 mfd. coil to the 6D8G grid, and carry out the procedure outlined above. This will tell you if the oscillator shunt trimmer only is correctly adjusted, or the right signal setting has been used on the test generator. In this case ONLY the image and fundamental will have the same intensity.

When you are sure the oscillator circuit is correct, place the signal on the grid of the 6S70 R.F. tube, and repeat the procedure on the R.F. coil. In this case when correct alignment has been made, the image will be lower in volume than the fundamental.

Replace the .1 mfd. condenser in the test generator lead with a 400 ohm resistor and connect to antenna terminal "A", and repeat procedure on antenna.

This method now assures you of correct individual alignment on each coil. Then proceed to touch up each coil except the oscillator, as outlined in 3 and 4.

FUNDAMENTAL & IMAGE FREQUENCY NOTES

A simple method of checking to determine if the receiver and generator are tuned for correct alignment is as follows:

Set the signal generator to 15000 K.C. Tune the receiver from 15000 slowly up to 16000 K.C. Two signals should be heard 940 K.C. apart on the receiver, namely, one lower in frequency than 15000 K.C. and the other higher. The correct point for alignment is the higher frequency on the receiver dial, the lower is the image. As a check, the receiver should be left tuned to the higher frequency. Increase the generator frequency which was set for 15000 K.C. slowly to approximately 16000 K.C. A signal should be heard near 16000 K.C. if the first setting on the generator was correct for alignment. No signal would indicate that the original setting was on the image frequency. If this occurs, make certain that you start from the beginning to be sure of your results.

After the correct setting has been found, and the alignment has been carried out, it will be noted that the image or lower frequency response on the receiver dial will always sound weaker than the true signal, if the tuned circuits have been correctly adjusted.

470 K.C. I.F. ADJUSTMENT

1. Connect high potential output lead from test generator in series with a .1 mfd. condenser to the grid of the 6D8G tube.
2. Connect output voltmeter (copper oxide rectifier type) across voice coil of speaker.
3. Set generator to supply a modulated 470 K.C. signal. Adjust generator output attenuator until a small output reading is obtained on the output voltmeter.
4. Adjust both trimmers on top of the first and second I.F. transformers (see diagram) for maximum output.
5. Retrim slightly the first I.F. trimmer.

MEDIUM BAND "M" ALIGNMENT

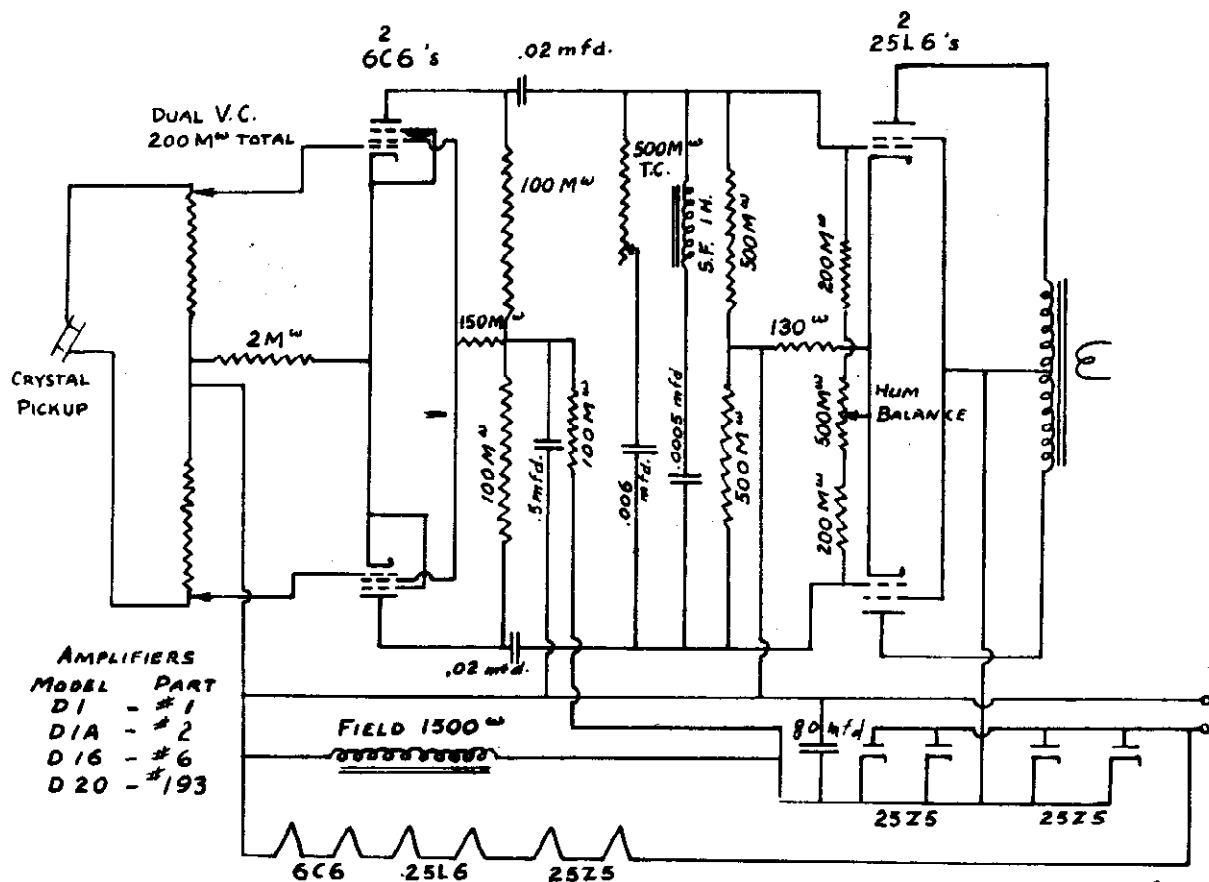

TURN THE WAVE BAND SELECTOR SWITCH TO THE "M" POSITION.
Set test generator for 1400 K.C. Connect high potential lead of test generator in series with a .1 mfd. condenser to grid of 6D8G tube. Tune receiver to 1400 K.C. (214.3 meters) on the tuning scale. If signal is not heard, leave scale pointer set to 1400 K.C. (214.3 meters), and adjust oscillator coil shunt trimmer slowly and carefully until signal is heard.

TOP VIEW OF CHASSIS

The oscillator coil of the receiver and dial are now set correctly, assuming the test generator calibration is correct. Remove test generator hot lead from 6D8G grid. Replace .1 mfd. condenser with 250 mfd. (.00025 mfd.) and connect to antenna terminal of receiver "A", all other settings to remain the same. Adjust R.F. coil shunt trimmer and then "ANT." coil shunt trimmer for maximum deflection. Return test generator to 600 K.C. (500 meters), and tune receiver to 600 K.C. (500 meters) until signal is heard. Adjust oscillator coil series trimmer slowly while rotating the gang condenser slowly about the signal for each small adjustment

MODELS M10-M20
I.F. 456KC

ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456 kc to the 6A7 grid. Connect an output meter across the secondary terminals of the speaker output transformer. With the weakest signal from the generator necessary to obtain .5 volt deflection on the output meter, peak the two trimmers on the first I. F. transformer and the single trimmer on the second I. F. transformer. This second I. F. transformer is located on the under side of the chassis.

R. F. Alignment. Insert a 200mmfd condenser in series with the antenna lead of the receiver and the signal generator. Set the receiver dial to 1400kc and the signal generator to the same frequency. Again with the weakest signal necessary to obtain .5 volt deflection of the output meter, adjust the terminals on both sections of the variable condenser. It is the utmost importance in making these various adjustments that the signal level be attenuated as far as possible in order to overcome the AVC action which would otherwise introduce serious errors and prevent obtaining optimum results.

ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456kc to the 6A7 grid. Connect an output meter across the secondary terminals of the speaker output transformer. With the weakest signal from the generator necessary to obtain a .5 volt deflection on the output meter, peak the trimmers on both I. F. Transformers.

R. F. Alignment. Insert a 200mmfd condenser in series with the antenna lead of the receiver and the signal generator. Switch the receiver to the broadcast band and set the dial to 1400kc. Set the signal generator at the same frequency. With the weakest signal necessary to obtain .5 volt deflection on the output meter, adjust the trimmers on the variable condenser. Set the receiver to 600kc and with a signal of the same frequency adjust the oscillator padder condenser. Repeat the above procedure until certain that optimum adjustment has been secured. Now rotate the band switch to the short wave position. With the signal generator feeding a 6.0mc signal into the set, adjust the trimmer condenser on the antenna coil while "rocking" the variable condenser with the dial indicating a setting of approximately 6.0mc. It is imperative that all of the above adjustments be made with the signal level attenuated as far as possible in order to overcome the AVC action which would otherwise introduce serious errors and prevent obtaining best results.

Wave Trap Alignment. With a signal of a fairly high order and a frequency of 456kc being fed into the antenna input, adjust the trimmer on the trap coil to minimum response.

AUTOMATIC RADIO MFG. CO., INC.

MODEL M60

REVISED ANTENNA CIRCUIT FOR MODEL M-60

For high capacity antenna (above 300 MMF), such as built in roof antenna or large running board antenna GREEN lead should be connected to antenna, RED lead connected to antenna cable shielding, and BLACK lead taped (not used).

For medium capacity antennas (150 to 300 MMF), such as rear vertical rod or overhead strip, RED lead is connected to antenna, BLACK lead should be grounded to cable shield, and GREEN wire taped (not used).

For low capacity antenna (below 150 MMF) such as a hinge mounted vertical rod or a cowl rod, the GREEN lead should be connected to the antenna, the BLACK lead should be grounded to the cable shield and the RED lead should be taped, and pushed back into the cable.

ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456 kc to the 6A7 grid. Connect an output meter across the secondary terminals of the speaker output transformer. With the weakest signal from the generator necessary to obtain .5 volt deflection on the output meter, peak the trimmers on both I. F. transformers.

R. F. Alignment. Insert a 200mmfd condenser in series with the antenna lead of the receiver and the signal generator. Set the receiver dial to 1400kc and the signal generator to the same frequency. Again with the weakest signal necessary to obtain 1 volt deflection of the output meter, adjust the trimmers on the oscillator, antenna and interstage sections of the variable condenser. Tune the receiver to 600kc and set the signal generator to this frequency. Adjust the padder condenser for maximum signal response to minimum signal input. Repeat the high frequency alignment.

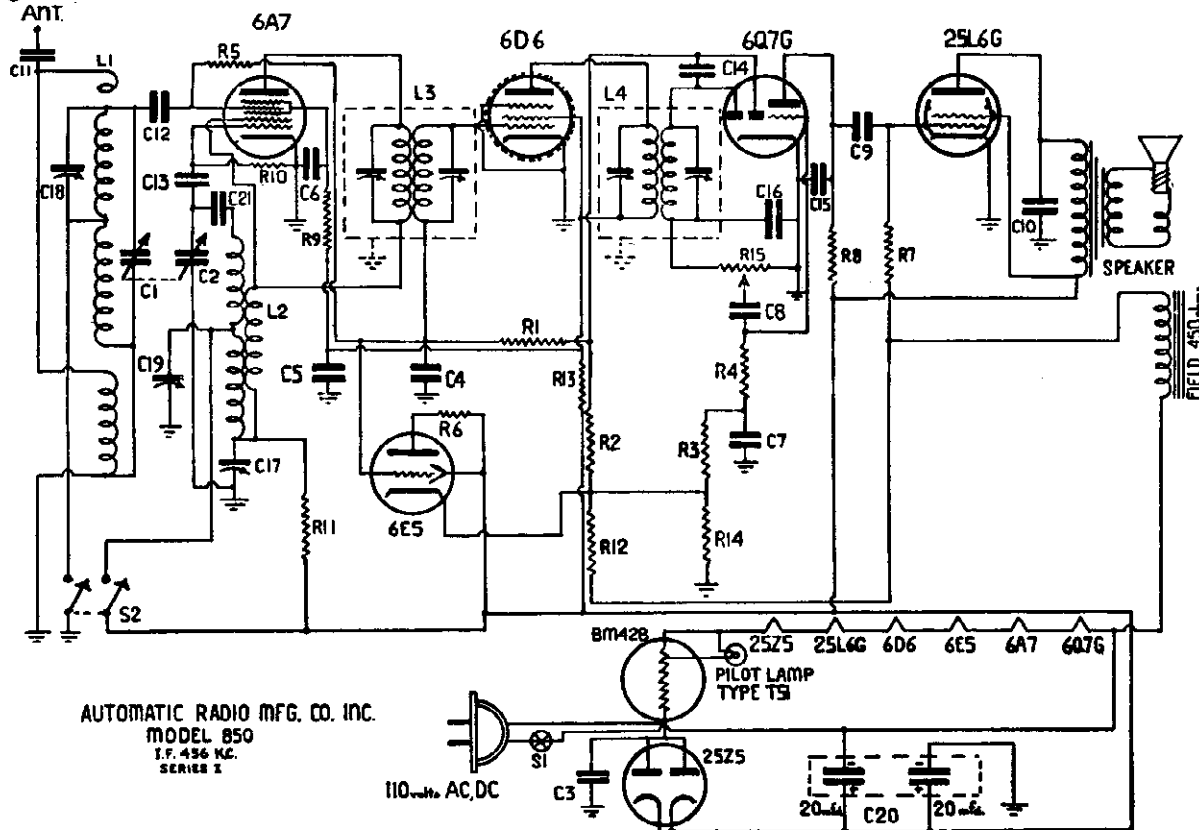

It is of the utmost importance in making these various adjustments that the signal level be attenuated as far as possible in order to overcome the AVC action which would otherwise introduce serious errors and prevent obtaining optimum results.

MODEL 850

Schematic, Parts Alignment

AUTOMATIC RADIO MFG. CO., INC.

AUTOMATIC RADIO MFG. CO. INC.
MODEL 850
I.F. 456 KC.
SERIES 2

ALIGNMENT PROCEDURE

I. F. Alignment. The intermediate frequency to which this set should be adjusted is 456 K.C. To align the intermediate frequency transformers properly, a signal generator emitting a signal of 456 K.C. should be coupled to the signal control grid of the 6A7 tube through a 200 mmfd condenser. An output meter should be connected across the voice coil of the speaker. The four trimmers mounted internally in the top of the two I. F. cans should be adjusted to resonance. The output of the signal generator should be attenuated so as to provide the weakest possible signal necessary to produce a .5 volt deflection on the output meter.

R. F. Alignment. Adjust the signal generator to 17.4 MC. Feed this signal into the antenna lead of the receiver through a 400 ohm resistor. Rotate the band switch on the receiver to the Short Wave position and set the tuning dial to 17.4 on the Short Wave Scale. Adjust the trimmer on the rear section for maximum signal output. Rotate the Band Switch to the broadcast position. Replace the 400 ohm resistor in the Oscillator lead with a 200 mmfd condenser. Set the signal generator to 1560 K.C. and tune the receiver to the same frequency. Adjust the small trimmer condenser which is located near the Oscillator coil underneath the Chassis, to maximum signal response. Attenuate the output of the signal generator to the extent necessary for maintaining a deflection of .5 volts on the output meter and adjust the trimmer mounted on the front section of the variable condenser to resonance. Set the signal generator and the receiver at 600 K.C. and adjust the padder condenser for optimum response. Repeat the last two adjustments to insure accuracy of alignment. Rotate the Band Switch to the Short Wave position and with the signal generator and receiver tuned to 15 MC, adjust the small trimmer condenser which is located near the Short Wave Antenna coil. This last operation should be made with the 400 ohm resistor in the antenna circuit.

It is imperative that all adjustments be made with the minimum signal necessary to obtain the designated deflection on the output meter. This will obviate any difficulty arising from the A.V.C. action of the receiver, and will permit adjustment to absolute resonance.

NOTE: R11, Part No. 101-44 Variable Filament Rheostat is adjusted at the factory to keep the filament voltage of the tubes at 2 volts.

TUBES:

The tube complement of this chassis consists of the following tubes:

The type and function of each tube is as follows:

- 1—Type 1A6 Pentagrid Mixer, First Detector-oscillator.
- 1—Type 1A4 Super Control R. F. Tetrode I. F. Amplifier (465 K.C.)
- 1—Type 1F6 Duplex Diode Pentode, Second Detector, A.V.C. and First Audio.
- 1—Type 1F4 Pentode Output Amplifier.

ALIGNING I.F. TRANSFORMERS: (465 K. C.):

- Part No. 108-85 Output I.F. Transformer.
- Part No. 108-84 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view)

1. With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - (a) Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 1A4 tube, and adjust the output I.F. transformer (No. 108-85) to resonance.
 - (b) Move oscillator output clip from grid of 1A4 to grid cap of 1A6 and adjust input I.F. transformer (No. 108-84) to resonance.
 - (c) With oscillator still connected to 1A6, readjust output I.F. transformer (108-85) if necessary.

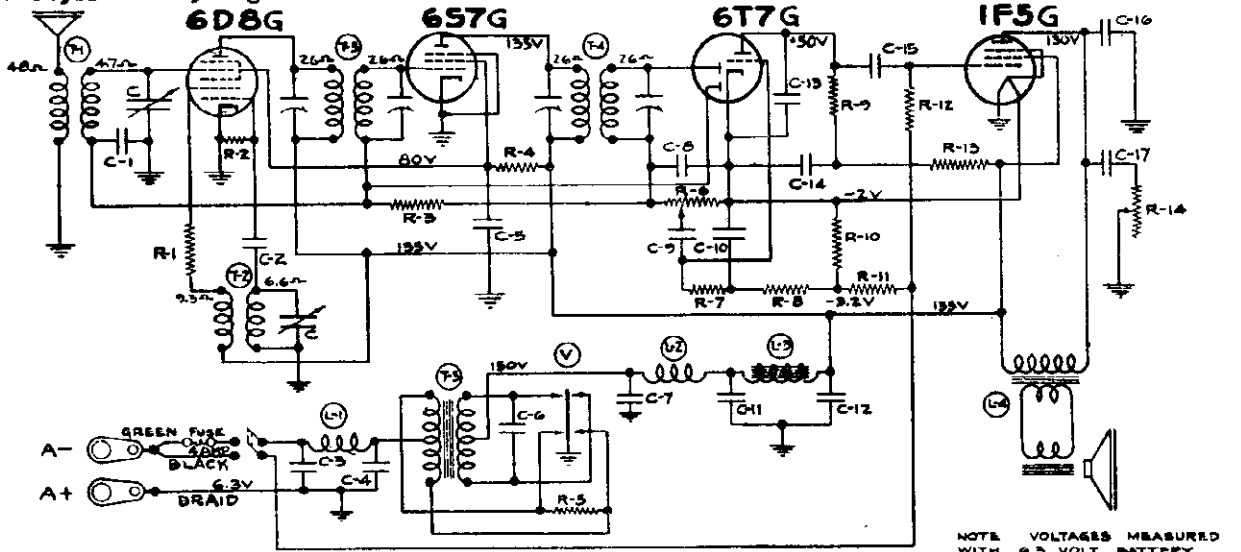

R.F. ALIGNMENT: (535-1720 K.C.)

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mfd. condenser to tan antenna and black ground leads and make the following adjustments:
 - (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer (rear of gang condenser).
 - (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance (front section of gang condenser).
 - (c) Check sensitivity at 600 and 1000 kilocycles.

 - L3 105-30 Filter Choke
 - L4 114-63 Speaker (P. M. Dynamic)
 - V 126-4 Vibrator
 - C Variable Condenser

The type and function of each tube is as follows:

- 1—Type 6D8G Pentagrid Mixer, First Detector-oscillator.
- 1—Type 6S7G Remote Cut-off Pentode I. F. Amplifier (465 K.C.)
- 1—Type 6T7G Duplex Diode Triode, Second Detector, A.V.C. and First Audio.
- 1—Type 1F5G Pentode Output Amplifier.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 1F5G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS: (465 K. C.):

- Part No. 108-85 Output I.F. Transformer.
- Part No. 108-84 Input I.F. Transformer.

These I.F. Transformers have two adjustments, both of which are accessible from the top of chassis (see fig. 1, top view page 2).

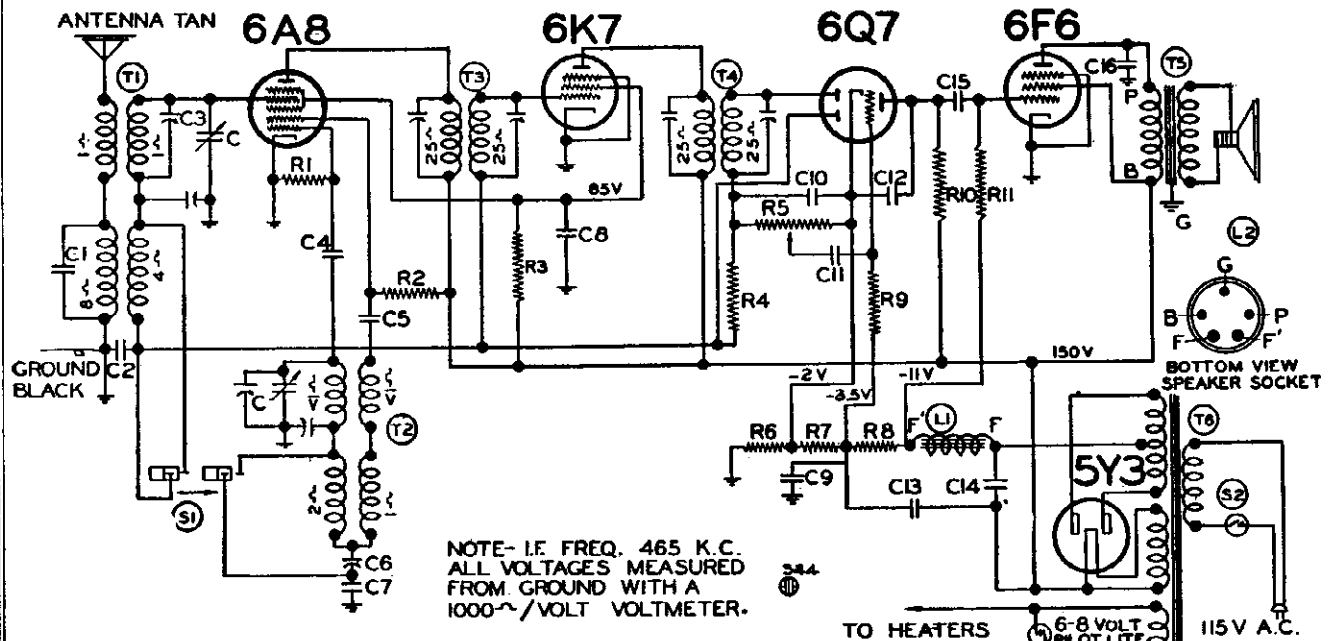

- With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments.
 - Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 6S7G tube, and adjust the output I.F. transformer (No. 108-85) to resonance.
 - Move oscillator output clip from grid of 6S7G to grid cap of 6D8G and adjust input I.F. transformer (No. 108-84) to resonance.
 - With oscillator still connected to 6D8G readjust output I.F. transformer (108-85) if necessary.

R. F. ALIGNMENT: (535-1720 K.C.)

- With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mmf. condenser to tan antenna and black ground leads and make the following adjustments:
 - With external oscillator set at 1720 kilocycles, adjust oscillator trimmer (rear of gang condenser).
 - Re-set external oscillator to 1400 kilocycles, rotate condenser, pick-up oscillator signal and adjust antenna trimmer to resonance (front section of gang condenser).
 - Check sensitivity at 600 and 1000 kilocycles.

FREQUENCY RANGE

2000 to 7000 K.C. (Kilocycles) Vol. Control On-Off Switch Tuning Band Control Switch

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes:

- 1—Type 6A8G Pentagrid mixer, first detector-oscillator.
- 1—Type 6K7G Remote cut-off pentode I.F. amplifier (465 K.C.)
- 1—Type 6Q7G duplex diode triode second detector, A.V.C. and audio.
- 1—Type 6F6G—pentode output amplifier.
- 1—Type 5Y3G or 5W4—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

MODEL 588, Series A
Trimmers, Alignment

BELMONT RADIO CORP.

FIG. 3.—BOTTOM VIEW SHOWING TRIMMERS

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-103 Output I.F. Transformer

Part No. 108-104 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser in its minimum capacity position, plates entirely out of mesh, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-103) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7G to grid cap of 6A8G and adjust input I.F. transformer (No. 108-104) to resonance.

SHORT WAVE BAND ALIGNMENT:

2000 to 7000 Kilocycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 6 megacycles and connected in series with "Dummy 3" to the antenna and ground leads, make the following adjustments:

(a) Move dial pointer to 6 megacycles and adjust short wave oscillator trimmer to resonance.

This adjustment is the trimmer mounted on the top of rear section of the variable gang condenser (see Fig. 1, top view).

(b) Adjust short wave antenna trimmer (Adjustment Number 1), to resonance (see Fig. 3, bottom view).

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground leads make following adjustments:

(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 3, see bottom view of chassis, Fig. 3).

(b) Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 2), to resonance.

(c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 4), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).

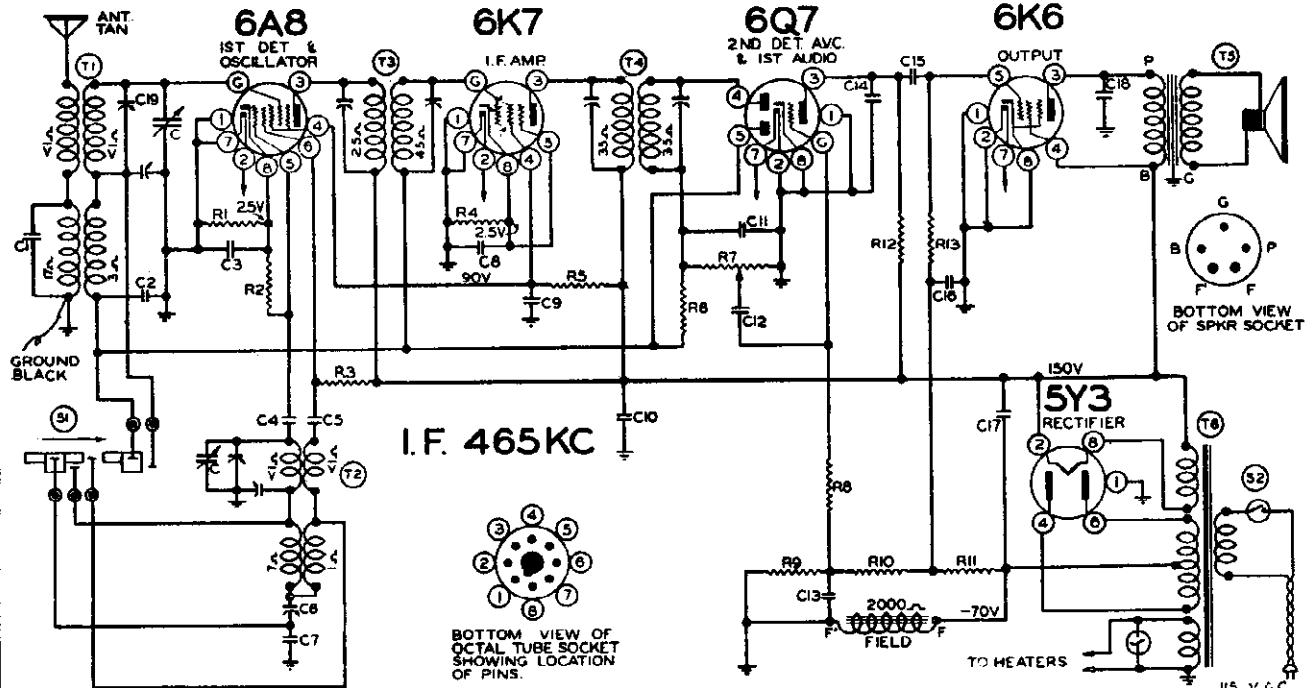

(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

(e) Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

NOTE--I.F. FREQ. 465 K.C.
ALL VOLTAGES MEASURED FROM
B- WITH A 1000 OHM PER
VOLT VOLTMETER. ANTENNA
GROUNDED TO CHASSIS Φ 352

- (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance. This adjustment is on the top of rear section of variable gang condenser. (See Fig. 1).
- (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. (Top of front section of gang condenser).
- (c) Check sensitivity at 600 and 1000 kilocycles.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 119 volt A.C. or D.C. line.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

- Part No. 108-83B Output I.F. Transformer
 - Part No. 108-82B Input I.F. Transformer
- These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see Fig. 1).

1. With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - (a) Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-83B) to resonance.
 - (b) Move oscillator output clip from grid of 6K7G to grid of 6A8G and adjust input I.F. transformer (No. 108-82B) to resonance.
 - (c) With oscillator still connected to 6A8G, readjust output I.F. transformer (108-83B) if necessary.

R.F. ALIGNMENT: (535-1720 K.C.)

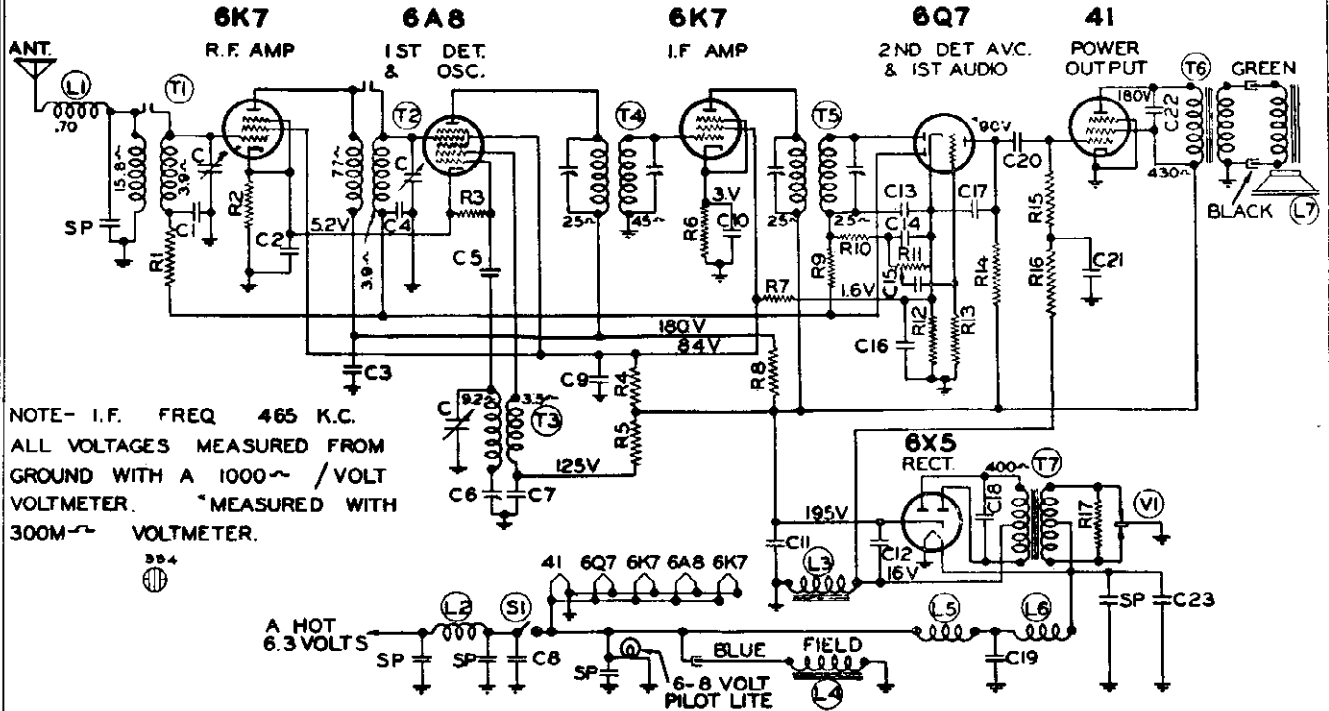

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mmf. condenser to the antenna lead and chassis ground and make the following adjustments:

CONNECTIONS TO BATTERY

The battery cable, number 107-82, (red wire with fuse receptacle at one end and terminal lug at other end) must be connected to battery terminal of ammeter. At the same time connect ammeter capacitor, number 148-3, to battery terminal of ammeter, other end of condenser to any convenient grounded screw on back of instrument panel. Make certain that insulating sleeve is slipped over fuse when fuse is placed in receptacle, before connecting to short battery cable from receiver.

When connected properly, the discharge due to current drawn by the receiver should not indicate on the ammeter. This is important, since if improperly connected, as shown by the deflection of ammeter, additional motor interference may be encountered.

MODEL 661

**Alignment, Assembly
Wiring Data**

BELMONT RADIO CORP.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

DESCRIPTION

Model No. 661 is a six-tube superheterodyne receiver having a tuning range of 530 K.C. to 1550 K.C., operates from a 6.0 volt storage battery and uses the automotive type 6.3 volt tubes. The "B" supply is obtained from a vibrator with a tube rectifier.

The I.F. frequency used is 465 K.C., the R.F. end of the receiver consisting of a high gain iron core antenna coil which gives high signal to noise ratio and an R.F. stage especially designed to give high image rejection and high I.F. attenuation. The I.F. transformers are designed to give high gain and selectivity and yet to have a broad nose for ease of tuning and hi-fidelity response. They are of the air core type and wound with solid wire to give minimum drift and variation of gain due to climatic changes.

This receiver has been carefully designed to facilitate servicing, the top and bottom covers are both removable and are fastened in place by spring clips, self tapping screws and trimount buttons.

DUMMY ANTENNAS

The dummy antennas referred to in the following instructions are:

"I.F. Dummy" —A .5 mfd. condenser connected in series with the test oscillator output lead.

"Broadcast Dummy"—A 175 mmfd. condenser connected in series with the output lead of the test oscillator.

RESONANCE INDICATOR

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 41 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

I.F. ALIGNMENT: (465 K.C.)

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 465 K.C. in series with I.F. dummy antenna, to grid of 6K7 I.F. tube.
2. Adjust trimmer condensers of output I.F. transformer No. 108-98 to resonance with oscillator.
3. Move test oscillator connection to grid of 6A8 tube and adjust trimmer condensers of input I.F. transformer No. 108-96B to resonance with oscillator. See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT

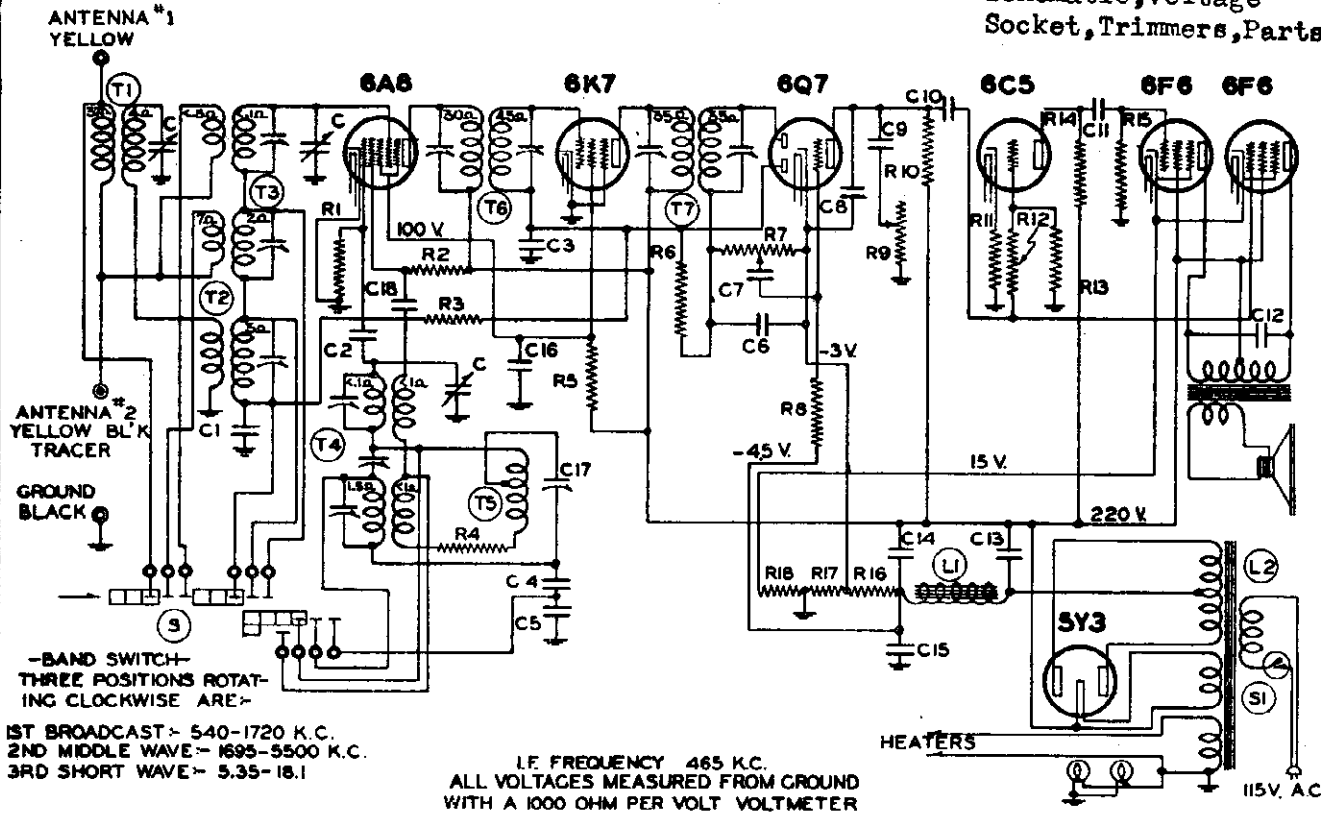

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. in series with broadcast dummy to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is on the middle section of the three-gang condenser—see top view, Fig. 2).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust R.F. and antenna trimmers to resonance (see top view, Fig. 2).
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to 600 K.C. Adjust series pad, rocking gang condenser to and fro, at the same time adjusting series pad for maximum gain. This adjustment is accessible from the top of chassis—see top view.
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again.
6. Check for sensitivity at 1000 K.C. by setting test oscillator to this frequency and picking up the signal by rotating variable condenser. Under no circumstances bend plates of variable condenser sections to correct tracking.

MODEL 740

Alignment, Trimmers

BELMONT RADIO CORP.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-106 Output I.F. Transformer

Part No. 108-105 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

- With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-106) to resonance.
 - With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6A8G and adjust input I.F. transformer (No. 108-105) to resonance.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

- With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
 - Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3.)
 - Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)

- Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

- With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
 - Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
 - Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

- With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
 - Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
 - Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.
 - Recheck broadcast band alignment.

BELMONT RADIO CORP.

MODEL 787 - Series A

DESCRIPTION:

Model 787 is a seven tube A.C. all wave superheterodyne receiver. It has a tuning range of 535 K.C. to 1625 megacycles in three bands, and is characterized by its exceptional selectivity and high fidelity.

A separate oscillator, effective automatic volume control, broad nose sharp skirt selectivity and new 0725 oval model.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 250 volts.

1. With volume control full on (the extreme right of the rotation), the band changing switch in the broadcast position (extreme left of the rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles in series with "Dummy 1", to the control grid cap of the type 6X7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-65 to resonance.

With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments:

- (b) With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments: (a) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (b) Re-set external oscillator to 1560 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (d) Re-set external oscillator to 1625 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (e) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.)

SERVICE NOTES:

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open bypass condensers, short each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, statoring, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open bypass condensers frequently cause oscillation and distorted tone.

DUMMY ANTENNAS: The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS; (465 K.C.): Part No. 108-22 Output I.F. Transformer. These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

MODEL 879 - Series A

DESCRIPTION

The tube complement of this chassis is as follows: 1-Type 6B7 Pentode cut-off pentode R.F. amplifier 1-Type 6B7 pentode first detector 1-Type 6C5 Oscillator 1-Type 6X7 Diode triode pentode I.F. amplifier (465 KC.) 1-Type 6Q7 Duplex diode triode second detector, A.V.C. and universal.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 250 volts.

1. With volume control full on (the extreme right of the rotation), the band changing switch in the broadcast position (extreme left of the rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles in series with "Dummy 1", to the control grid cap of the type 6X7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-65 to resonance.

With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments:

- (b) With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments: (a) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (b) Re-set external oscillator to 1560 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.)

SERVICE NOTES:

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open bypass condensers, short each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, statoring, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open bypass condensers frequently cause oscillation and distorted tone.

DUMMY ANTENNAS: The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS; (465 K.C.): Part No. 108-22 Output I.F. Transformer. These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of the rotation), the band changing switch in the broadcast position (extreme left of the rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles in series with "Dummy 1", to the control grid cap of the type 6X7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-65 to resonance.

With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments:

- (b) With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments: (a) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (b) Re-set external oscillator to 1560 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.)

SERVICE NOTES:

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open bypass condensers, short each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, statoring, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open bypass condensers frequently cause oscillation and distorted tone.

DUMMY ANTENNAS: The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

MODEL 879 - Series A

ALIGNING I.F. TRANSFORMERS (465 K.C.) Part No. 108-22 Output I.F. Transformer. These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view, Fig. 1).

1. With volume control full on (the extreme right of the rotation), the band changing switch in the broadcast position (extreme left of the rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles in series with "Dummy 1", to the control grid cap of the type 6X7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-65 to resonance.

With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments:

- (b) With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments: (a) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (b) Re-set external oscillator to 1560 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.)

SERVICE NOTES:

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open bypass condensers, short each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, statoring, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open bypass condensers frequently cause oscillation and distorted tone.

DUMMY ANTENNAS: The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS; (465 K.C.): Part No. 108-22 Output I.F. Transformer. These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of the rotation), the band changing switch in the broadcast position (extreme left of the rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles in series with "Dummy 1", to the control grid cap of the type 6X7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-65 to resonance.

With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments:

- (b) With "Dummy 1" still connected, move oscillator output tap to approximately 1400 kilocycle, make the following adjustments: (a) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.) (b) Re-set external oscillator to 1560 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 5) until maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.) 600 K.C. and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., reading if necessary, by 10 and 15 until by adjusting series pad maximum output is obtained, then adjustment is located which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 3.) (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum, and adjust I.F. transformer 108-65 to resonance. (See bottom view of chassis, Fig. 3.)

SERVICE NOTES:

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open bypass condensers, short each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, statoring, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open bypass condensers frequently cause oscillation and distorted tone.

DUMMY ANTENNAS: The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

MODEL 804

Alignment, Trimmers

BELMONT RADIO CORP.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the two plate terminals of the type 19 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-92 Output I.F. Transformer
Part No. 108-93 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6S7G tube, and adjust the output I.F. transformer (No. 108-92) to resonance.
- With "Dummy 1" still connected, move oscillator output clip from grid of 6S7G to grid cap to 6D8G and adjust input I.F. transformer (No. 108-93) to resonance.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 18 megacycles and connected in series with "Dummy 3" to the antenna and ground posts, make the following adjustments:

- Move dial pointer to 18 megacycles and adjust short wave oscillator trimmer (adjustment number 1) to resonance.
- Re-set external oscillator to 17 megacycles and pick up signal by rotating variable condenser and adjust short wave R.F. trimmer (adjustment number 8), and short wave antenna trimmer (adjustment number 9), to resonance.
- Re-set external oscillator and check set at 18.1 megacycles and 6 megacycles for band coverage and sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle signal can be tuned in not only at 18.3 on the dial but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5.5 megacycles and connected in series with "Dummy 3" to the antenna and ground posts make the following adjustments:

- Move dial pointer to 5.5 megacycles and adjust middle wave oscillator trimmer (adjustment number 2) to resonance.
- Re-set external oscillator to 5 megacycles and pick up signal by rotating variable condenser and adjust middle wave R.F. trimmer (adjustment number 10), and middle wave antenna trimmer (adjustment number 5), to resonance.
- Re-set external oscillator and check sensitivity at 1700 kilocycles.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground posts, make following adjustments:

- Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 4; see bottom view of coil assembly, Fig. 3)
- Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast R.F. trimmer (adjustment number 6) and broadcast antenna trimmer (adjustment number 7), to resonance.
- Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 3), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

MODEL 822
Alignment

BELMONT RADIO CORP.

BATTERIES REQUIRED:

The following batteries are required:

- 2—45 Volt "B" Batteries.
- 1—4½ Volt "C" Battery.
- 1—8 Volt Dry "A" Battery or 2 Volt Storage Battery.

TUBES:

The tube complement of this chassis is as follows:

- 1—Type 1A6 Pentagrid Mixer, First Detector.
- 1—Type 1A4 Tetrode First I.F. Amplifier (465 K.C.)
- 1—Type 34 Remote Cut-Off Pentode, 2nd I.F. Amplifier (465 K.C.)
- 1—Type 30 Oscillator.
- 1—Type 30 Second Detector and A. V. C.
- 1—Type 34 A.F. Amplifier.
- 1—Type 30 Driver Amplifier.
- 1—Type 19 Class "B" Push-Pull Output Amplifier.

SERVICE NOTES:

Voltagages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltagages as indicated on diagram, are measured with a new set of batteries.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

The approximate current consumption is as follows:

"A"—660 ma., "B"—18 to 24 ma.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the two plate terminals of the type 19 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

- Part No. 108-79 Output I.F. Transformer
- Part No. 108-78 Interstage I.F. Transformer
- Part No. 108-77 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 34 tube, and adjust the output I.F. transformer (No. 108-79) to resonance.

- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 34 to grid cap to 1A4 and adjust interstage I.F. transformer (No. 108-78) to resonance.

- (c) Move oscillator to grid cap of 1A6 and adjust input I.F. transformer (No. 108-77).

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground posts, make following adjustments:

- (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 1; see bottom view of coil assembly, Fig. 3)

- (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment).

- (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).

- (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

- (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.2 to 18.3 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the antenna and ground posts, make the following adjustments:

- (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 3) and short wave antenna (adjustment number 6) to resonance.

- (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.

- (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle signal can be tuned in not only at 18.3 on the dial but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1695 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the antenna and ground posts make the following adjustments:

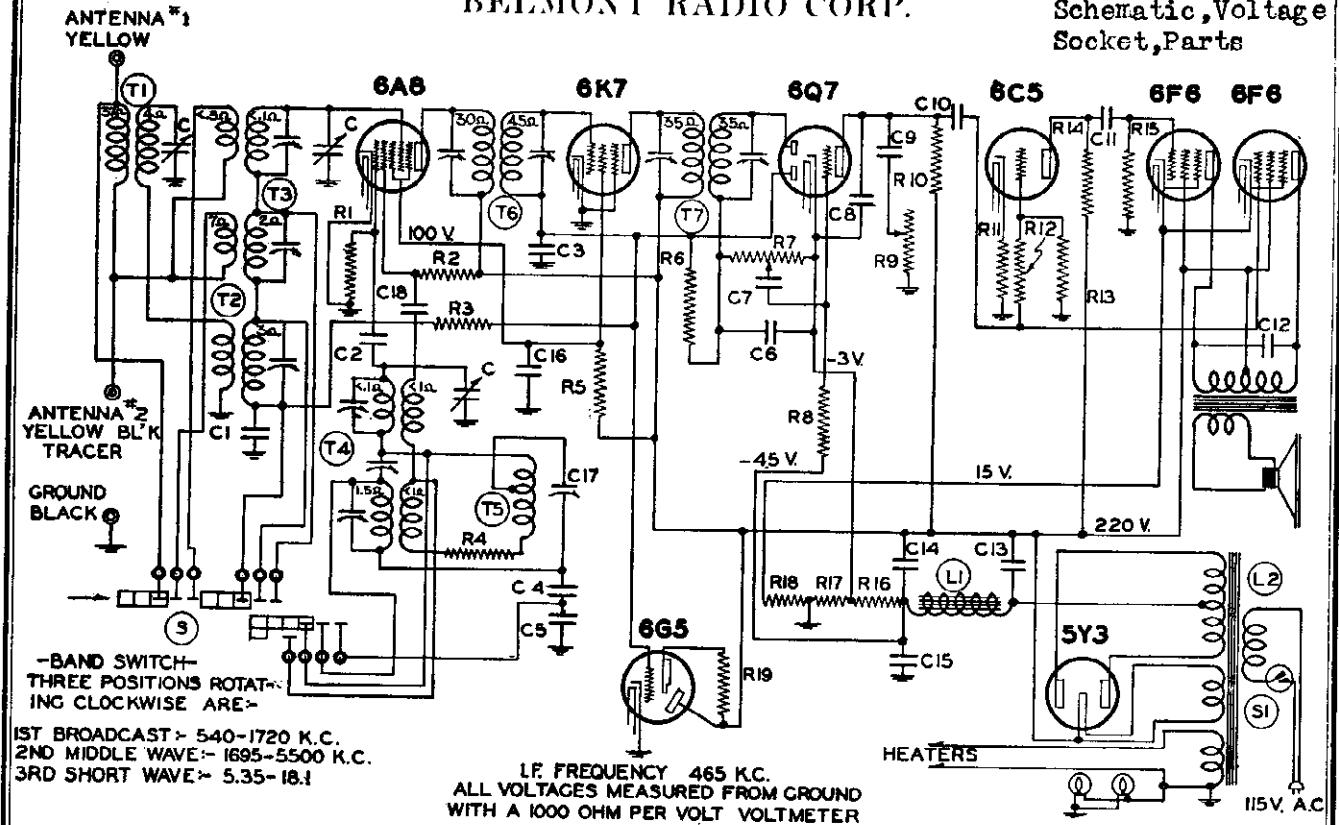

- (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (adjustment number 2) and middle wave antenna (adjustment number 5) to resonance.

- (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.

- (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

MODEL 840

Alignment, Trimmers

BELMONT RADIO CORP.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-106 Output I.F. Transformer
Part No. 108-105 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-106) to resonance.
- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6A8G and adjust input I.F. transformer (No. 108-105) to resonance.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:

- (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3.)
- (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)

- (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
- (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
 - (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
 - (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
 - (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
 - (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.
 - (d) Recheck broadcast band alignment.

BELMONT RADIO CORP.

across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION: No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS:
 (465 K.C.) (645.1 Meters)
 Part No. 108-73 Output I. F. Transformer.
 Part No. 108-88 Input I. F. Transformer.

- These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).
1. With volume control full on (the extreme right of its rotation), the band changing switch in the medium wave position, (center of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
 - (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-88) to resonance.
 - (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE:
 The following adjustments to be made after the I.F.'s have been aligned as explained above.

- SHORT WAVE BAND ALIGNMENT:**
 16.5 Meters (18.2 Mc.) to 56.5 Meters (5.3 Mc.)
1. With band changing switch in the short wave position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Set external oscillator to 16.5 meters (18.2 Mc.) and adjust short wave oscillator trimmer (adjustment number 3, see Fig. 3) to resonance.
 - (b) Re-set external oscillator to 17.6 meters (17.0 Mc.) and pick up signal by rotating gang condenser. Adjust short wave antenna trimmer (adjustment number 6) to resonance.
 - (c) Re-set external oscillator to 50 meters (6.0 Mc.) and check for sensitivity.

MEDIUM BAND ALIGNMENT:
 588 Meters (510 K.C.) to 187 Meters (1600 K.C.)

1. With band changing switch in the medium wave position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out-of mesh, and

LONG WAVE BAND ALIGNMENT:
 860 Meters (350 K.C.) to 2150 Meters (140 K.C.)

1. With band changing switch in the long wave position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator, connected in series with "Dummy 2," to tan antenna lead and black ground lead, make following adjustments:
 - (a) Set external oscillator to 860 meters (350 K.C.), and adjust long wave oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3).
 - (b) Re-set external oscillator to 925 meters (325 K.C.), rotate variable gang condenser and pick up signal. Adjust long wave antenna trimmer (Adjustment number 4) to resonance.
 - (c) Re-set external oscillator to 2000 meters (150 K.C.), and adjust long wave series pad to resonance by rotating condenser to approximately 2000 meters, rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
 - (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

IMPORTANT: This band must be completely rechecked after the medium wave band has been rechecked.

FIG. 3--BOTTOM VIEW (Showing Trimmers)
 Dummy Antennas:

The following dummy antennas are used in aligning the receiver, and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Medium and long wave) — Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

TEST FREQUENCIES USED:

Kilocycles	Meters
465	645.1
150	2000
350	850
325	925
600	500
1400	214
1600	187
6000	50.0
17000	17.6
18200	16.5

Resonance Indicator:
 Use as a resonance indicator an output meter connected

- with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
- (a) Set external oscillator to 187 meters (1600 K.C.) and adjust medium wave oscillator trimmer to resonance (adjustment number 2; see bottom view of coil assembly, Fig. 3).
 - (b) Re-set external oscillator to 214 meters (1400 K.C.), rotate variable gang condenser and pick-up signal. Adjust medium wave antenna trimmer (Adjustment number 5) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
 - (c) Re-set external oscillator to 500 meters (600 K.C.), and adjust medium wave series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
 - (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
 - (e) Check for tracking and sensitivity at 300 meters (1000 K.C.) Under no circumstances bend plates of variable condenser sections to correct tracking.
- IMPORTANT:** This band must be completely rechecked after the long wave band has been adjusted.
- LONG WAVE BAND ALIGNMENT:**
 860 Meters (350 K.C.) to 2150 Meters (140 K.C.)
1. With band changing switch in the long wave position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator, connected in series with "Dummy 2," to tan antenna lead and black ground lead, make following adjustments:
 - (a) Set external oscillator to 860 meters (350 K.C.), and adjust long wave oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3).
 - (b) Re-set external oscillator to 925 meters (325 K.C.), rotate variable gang condenser and pick up signal. Adjust long wave antenna trimmer (Adjustment number 4) to resonance.
 - (c) Re-set external oscillator to 2000 meters (150 K.C.), and adjust long wave series pad to resonance by rotating condenser to approximately 2000 meters, rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
 - (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

IMPORTANT: This band must be completely rechecked after the medium wave band has been rechecked.

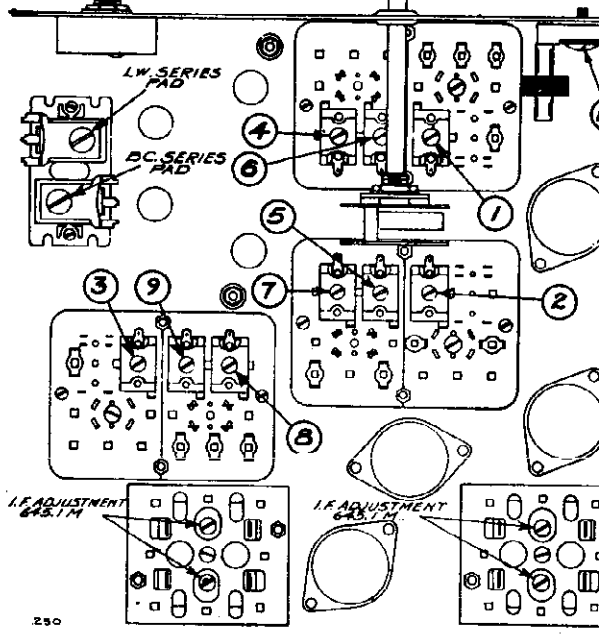

FIG. 2-BOTTOM VIEW (Showing Trimmer)

MODEL 856, Series A
Alignment**BELMONT RADIO CORP.****POWER SUPPLY:**

This receiver is normally supplied with a transformer for operation on 50 cycles (may be higher in frequency, not lower) and with a primary designed for operation on 190-280 volts.

Mains transformer is provided with two taps, one for voltages 190-240 volts another for voltages 240-280 volts. These taps are accessible upon removing plate fastened with two wing nuts to back of chassis.

ALIGNING INSTRUCTIONS**Dummy Antennas**

The following dummy antennas are used in aligning the receiver, and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast and long wave)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

TEST FREQUENCIES USED

	Kilocycles	Meters
I. F.	465	645.1
Long Wave	150	2000
	370	810
	350	857
Broadcast	550	545
	1300	230
	1530	196
Short Wave	6000	50.0
	17000	17.6
	18100	16.6

ALIGNING I.F. TRANSFORMERS
(465 K.C.) (645.1 Meters)

Part No. 108-63 Output I.F. Transformer.
Part No. 108-64 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view).

- With volume control full on (the extreme right of its rotation), the band changing switch in the medium wave position (center of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 230 meters (1300 K.C.), make the following adjustments:
 - Connect external oscillator set at 645.1 meters (465 K.C.), in series with "Dummy 1," to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer (108-63) to resonance.
 - With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
 - With oscillator still connected to 6J7, readjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

SHORT WAVE BAND ALIGNMENT:
16.6 Meters (18.1 Mc.) to 54.5 Meters (5.5 Mc.)

- With band changing switch in the short wave position, extreme right of its rotation, and with the gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Set external oscillator to 16.6 meters (18.1 Mc.) and adjust short wave oscillator trimmer (adjustment number 8, see Fig. 2) to resonance.
 - Re-set external oscillator to 17.6 meters (17.0 Mc.) and pick up signal by rotating gang condenser. Adjust short wave R.F. trimmer (adjustment number 7) and short wave antenna trimmer (adjustment number 6) to resonance.

- Re-set external oscillator to 50 meters (6.0 Mc.) and check for sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MEDIUM OR BROADCAST BAND ALIGNMENT:
590 Meters (508 K.C.) to 196 Meters (1530 K.C.)

- With band changing switch in the medium wave position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
 - Set external oscillator to 196 meters (1530 K.C.) and adjust medium wave oscillator trimmer to resonance (adjustment number 9; see bottom view of coil assembly, Fig. 2.)
 - Re-set external oscillator to 230 meters (1300 K.C.), rotate variable gang condenser and pick up signal. Adjust medium wave R.F. trimmer (adjustment number 5) and medium wave antenna trimmer (adjustment number 4) to resonance.
 - Re-set external oscillator to 545 meters (550 K.C.) and adjust medium wave series pad to resonance by rotating condenser to approximately 550 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)
 - Repeat adjustments "a" and "b" until sensitivity is at its maximum.
 - Check for tracking and sensitivity at 300 meters (1000 K.C.) Under no circumstances bend plates of variable condenser sections to correct tracking.

IMPORTANT: This band must be completely rechecked after the long wave band has been adjusted.

LONG WAVE BAND ALIGNMENT:
810 Meters (370 K.C.) to 2100 Meters (143 K.C.)

- With band changing switch in the long wave position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
 - Set external oscillator to 810 meters (370 K.C.), and adjust long wave oscillator trimmer to resonance (adjustment number 3; see bottom view of coil assembly, Fig. 2.)
 - Re-set external oscillator to 857 meters (350 K.C.), rotate variable gang condenser and pick up signal. Adjust long wave R.F. trimmer (adjustment number 2) and long wave antenna trimmer (adjustment number 1) to resonance.
 - Re-set external oscillator to 2000 meters (150 K.C.), and adjust long wave series pad to resonance by rotating condenser to approximately 2000 meters, rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 2.)
 - Repeat adjustments "a" and "b" until sensitivity is at its maximum.

IMPORTANT: This band must be completely rechecked after the medium wave band has been rechecked.

WAVE TRAP ADJUSTMENT:

The circuit diagram of this receiver shows a wave trap part number 108-50 (T1) in the antenna circuit.

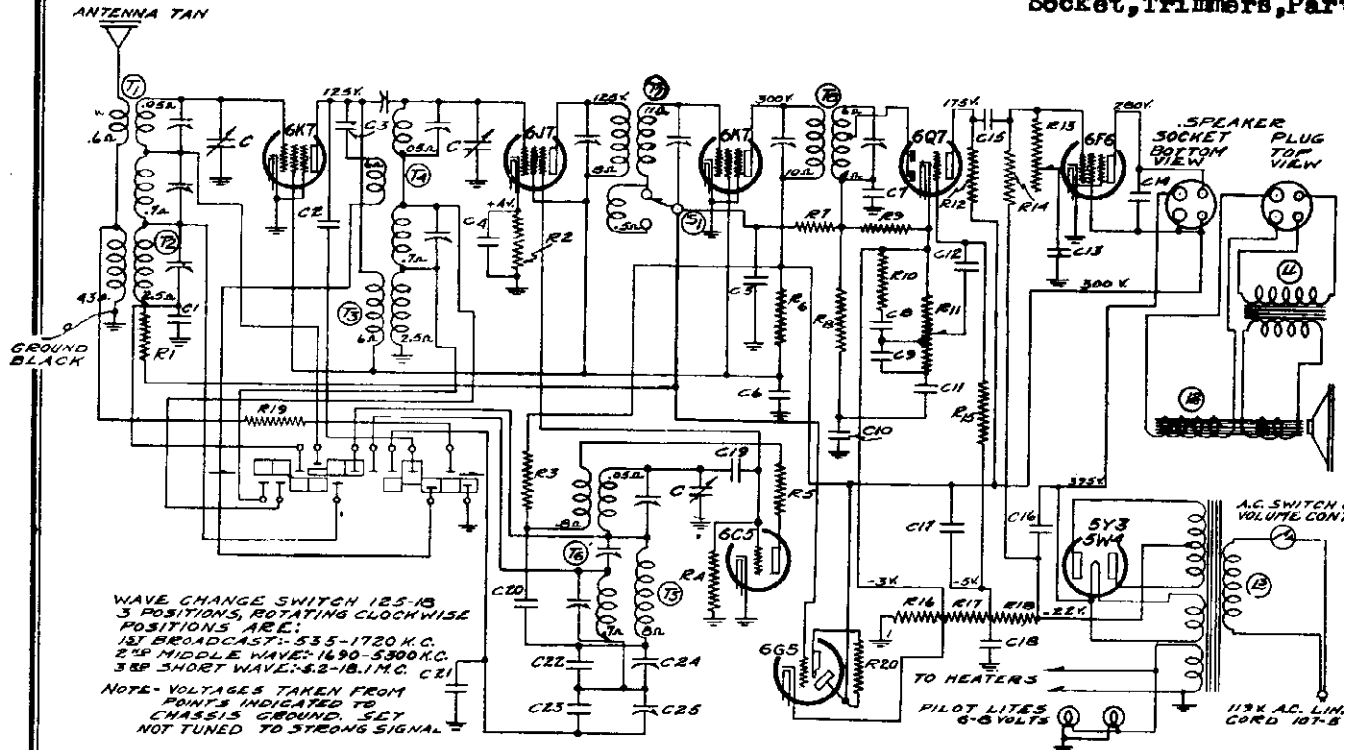

The purpose of this part is to trap out interfering frequencies close to the intermediate frequency (645.1 meters, 465 K.C.) used for the I.F. stage.

To properly adjust the trimmer for the wave trap (adjustment number 10, Fig. 2, page 2), proceed as follows:

- With band changing switch in the medium wave position, center of its rotation and the dial pointer set at 545 meters, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make the following adjustment:
 - Set external oscillator to 645.1 meters (465 K.C.) and adjust wave trap trimmer (adjustment number 10) for minimum response.

Alignment

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 119 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view, Fig. 1).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.
- With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
- With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:

FOR SERIES "A"

- Adjust broadcast series pad (adjustment number 5) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.

FOR SERIES "B"

- Adjust broadcast series pad (adjustment number 3) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.
- Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 1.
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

- With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.
 - Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

MIDDLE WAVE BAND ALIGNMENT:

FOR SERIES "A"

- With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 1800 K.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Rotate variable condenser to approximately 1800 K.C., tune in oscillator signal and adjust M.W. series pad (adjustment number 3) (see top view) to resonance. Slowly rock condenser to and fro while making this adjustment to be sure maximum output is obtained.
 - Set external oscillator at 5 M.C., rotate condenser, pick up signal and adjust intermediate wave R.F. (adjustment number 10), intermediate wave antenna (adjustment number 11) and intermediate wave oscillator (adjustment number 2) to resonance.

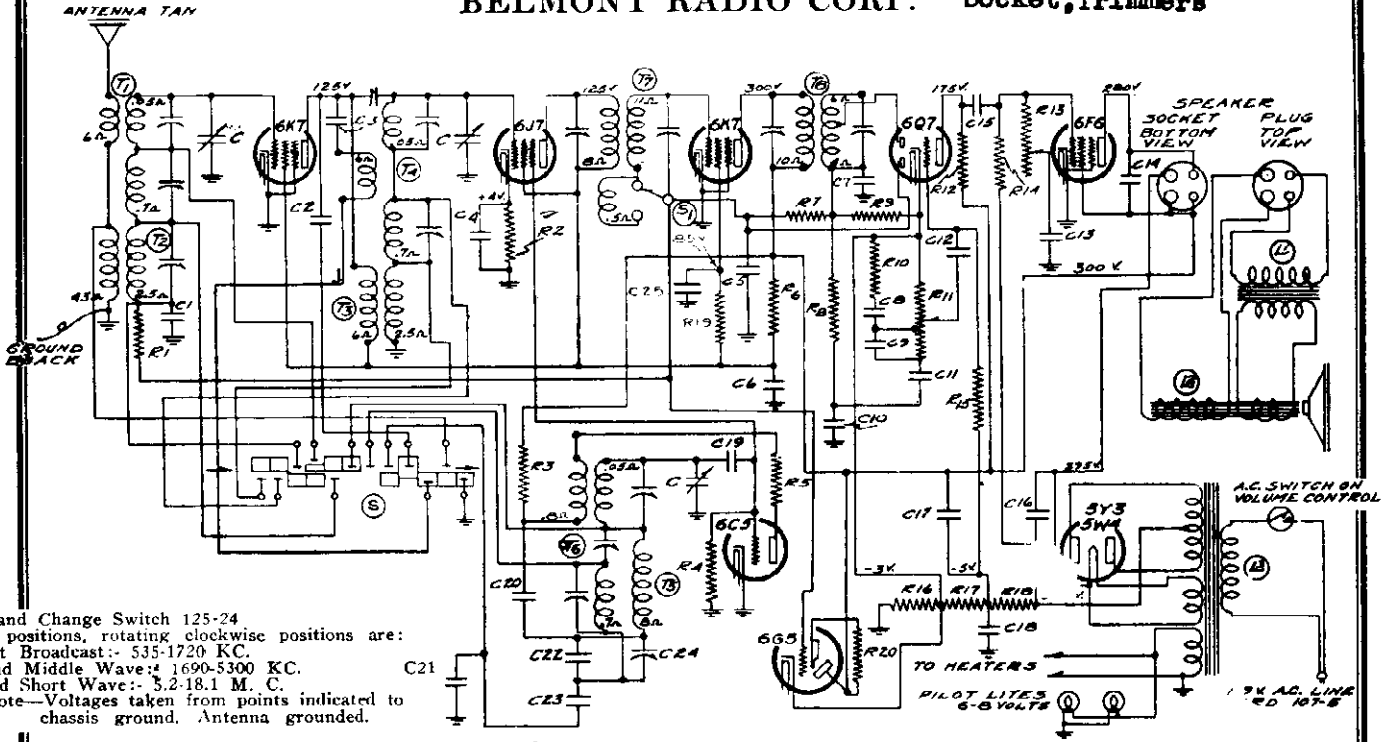

FOR SERIES "B"

- With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.
- NOTE—** Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. middle wave adjustments.

MODEL 890, Series A
Alignment
BELMONT RADIO CORP.
RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-92 Output I.F. Transformer
 Part No. 108-93 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-92) to resonance.
- With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6J7 and adjust input I.F. transformer (No. 108-93) to resonance.

BROADCAST BAND ALIGNMENT:
535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground leads make following adjustments:

- Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 4; see bottom view of coil assembly, Fig. 3)
- Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast R.F. trimmer (adjustment number 6) and broadcast antenna trimmer (adjustment number 7), to resonance.
- Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 3), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:
5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the antenna and ground leads, make the following adjustments:

- Move dial pointer to 17 megacycles and adjust short

wave oscillator trimmer (adjustment number 1) to resonance.

- Adjust short wave R.F. trimmer (adjustment number 8), and short wave antenna trimmer (adjustment number 9), to resonance.
- Re-set external oscillator and check set at 18.1 megacycles and 6 megacycles for band coverage and sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 17 megacycle signal can be tuned in not only at 17 on the dial but also at approximately 16.1 megacycles.

MIDDLE WAVE BAND ALIGNMENT:
1695 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 megacycles and connected in series with "Dummy 3" to the antenna and ground leads make the following adjustments:

- Move dial pointer to 5 megacycles and adjust middle wave oscillator trimmer (adjustment number 2) to resonance.
- Adjust middle wave R.F. trimmer (adjustment number 10), and middle wave antenna trimmer (adjustment number 5), to resonance.
- Re-set external oscillator and check sensitivity at 1800 kilocycles.
- Recheck broadcast band alignment.

ANTENNA AND GROUND LEADS:

You will notice three wires coming out of the back of the chassis, — the yellow wire and the yellow with black tracer wire are used for doublet antenna connections. The black wire is the ground connection.

For conventional types of antennas connect the yellow wire to the antenna lead and the yellow with black tracer and the black wire together to the ground lead.

When a doublet antenna is used connect the yellow wire and the yellow with black tracer wire to the doublet antenna and the solid black wire to the ground lead. (See Fig. 1—Top View, page 2).

ANTENNA:

For the best results an outside antenna approximately 75-100 feet long including the lead-in should be used. It should be erected as high as possible and as far from surrounding objects as practical. Both the antenna and lead-in should be placed at right angles to street car lines and incoming power lines and as far from any electrical apparatus which may be in the vicinity (such as elevator motors) as practical.

An inside antenna is not recommended, although it occasionally may serve as a temporary installation especially near powerful broadcasting stations. This type of antenna, however, will not be satisfactory in buildings of steel construction.

Reception on the short wave band can be sometimes improved by means of an approved doublet antenna.

DESCRIPTION:

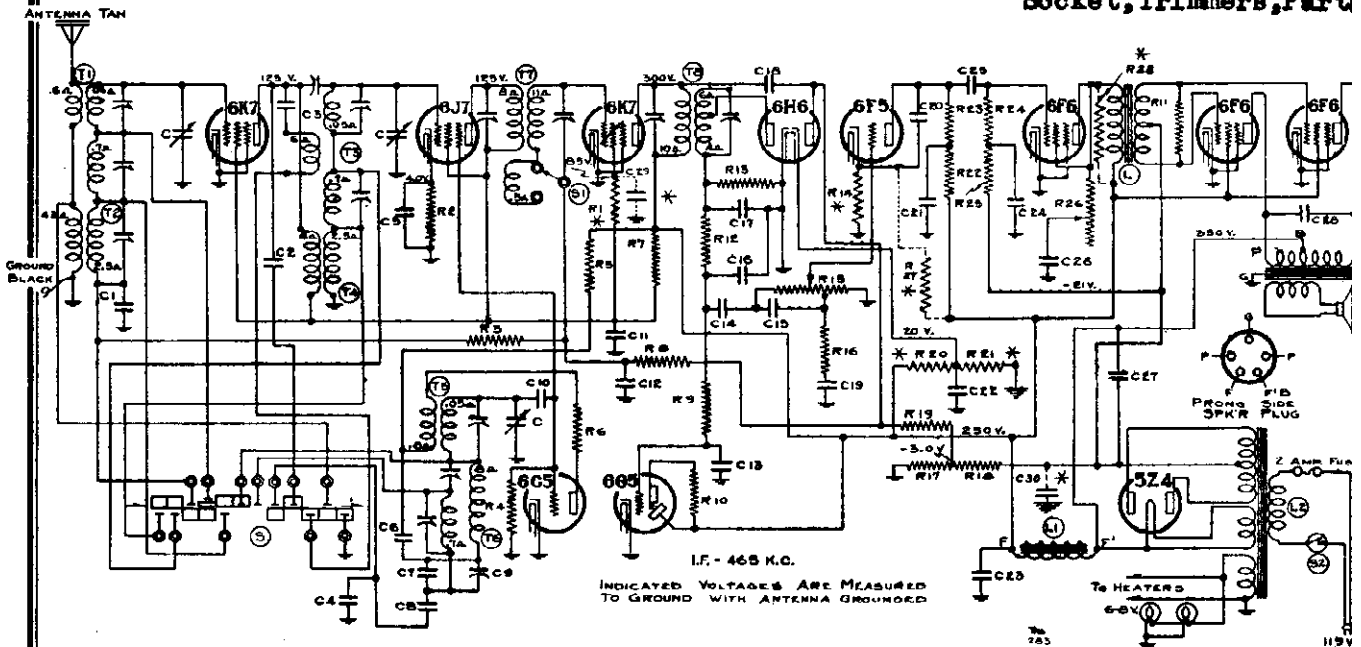

The tube complement of this chassis consists of the following metal and octal base glass tubes which are interchangeable with metal tubes:

- 1—Type 6K7 Remote cut-off pentode R.F. amplifier.
- 1—Type 6J7—pentode first detector.
- 1—Type 6C5 Oscillator.
- 1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
- 1—Type 6Q7G duplex diode triode second detector, A.V.C. and audio.
- 1—Type 6F6G—pentode output amplifier.
- 1—Type 5Y3G or 5W4—high vacuum rectifier.
- 1—Type 6G5 Cathode ray tuning indicator.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 110, 130, and 230 volts.

NOTE: Resistors and Condensers which are pre fixed with an asterisk (*) on the circuit diagram and parts list were added or the values changed during production to meet certain conditions. Resistors R1, R27, R28, and Condensers C29, C30 were added to correct certain variances of tube characteristics. Resistors R14, R20, R21 the values were changed. In some chassis the values of these resistors are as follows:
R14—2500 Ohm—1/4 Watt
R20—200M Ohm—1/4 Watt
R21—20M Ohm—1/4 Watt
Present values of these resistors are:
R14—500 Ohm—1/4 Watt
R20—100M Ohm—1/4 Watt
R21—10M Ohm—1/4 Watt

FIG. 1—BOTTOM VIEW SHOWING TRIMMERS

MODELS 1170, 1172**Alignment****BELMONT RADIO CORP.****DESCRIPTION**

The tube complement of this chassis is as follows:

- 1—Type 6K7 Remote cut-off pentode R.F. amplifier
- 1—Type 6J7 Pentode first detector
- 1—Type 6C5 Oscillator
- 1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
- 1—Type 6H6 Duplex diode second detector and A.V.C.
- 1—Type 6F5 First audio amplifier
- 1—Type 6F6 Triode driver stage
- 2—Type 6F6 Class AB Output pentodes in push-pull
- 1—Type 5Z4 High vacuum rectifier
- 1—Type 6G5 Cathode Ray Tuning Indicator.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

NOTE: DeLuxe Model 1172 differs only from the Model 1170 in that dual speakers and a de luxe console cabinet are used. Both chassis are identical and the circuit diagram, the alignment procedure and the parts list contained in this manual apply to both models.

Attention is called to the circuit diagram contained in this manual. Several minor changes were made during production of these models to correct certain conditions. These changes are shown on the circuit diagram in dotted lines and explained in detail. Some of the chassis were equipped with 5Z3 rectifier tubes in place of the 5Z4 and do not have a fuse assembly in the power line.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

This chassis is protected against damage from faulty tubes or abnormal line conditions by a fuse in the primary circuit.

If when set is turned on pilot lights do not light, look for a blown fuse.

This fuse is made accessible for replacement by removing fuse cover located on back flange of chassis, replace only with a 2 ampere fuse. If replacement fuse blows out, check tubes, (particularly 5Z4 rectifier) circuit, repair or replace defective tubes or parts.

NEVER ATTEMPT TO REPLACE FUSE WITHOUT FIRST DISCONNECTING POWER.

NEVER REPLACE WITH FUSE OTHER THAN 2 AMPERE RATING.

ALIGNING INSTRUCTIONS**Dummy Antennas**

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

- Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.
- Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.
- Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer

Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view Fig. 1).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.
 - (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
 - (c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Adjust broadcast series pad (adjustment number 3) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.
 - (b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 1.
 - (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

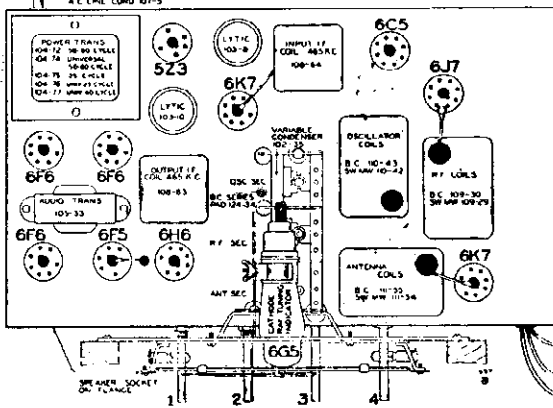

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.
 - (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

MIDDLE WAVE BAND ALIGNMENT:

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.
 - (b) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. middle wave adjustments.

MODEL 1170E
Alignment

BELMONT RADIO CORP.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a voltmeter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of the multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I. F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view Fig. 3).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the

type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.

- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
- (c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Adjust broadcast series pad (adjustment number 3) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 1.
 - (b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 3.
 - (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
 - (d) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.3 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.
 - (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle can be tuned in not only at 18.3 on the dial, but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

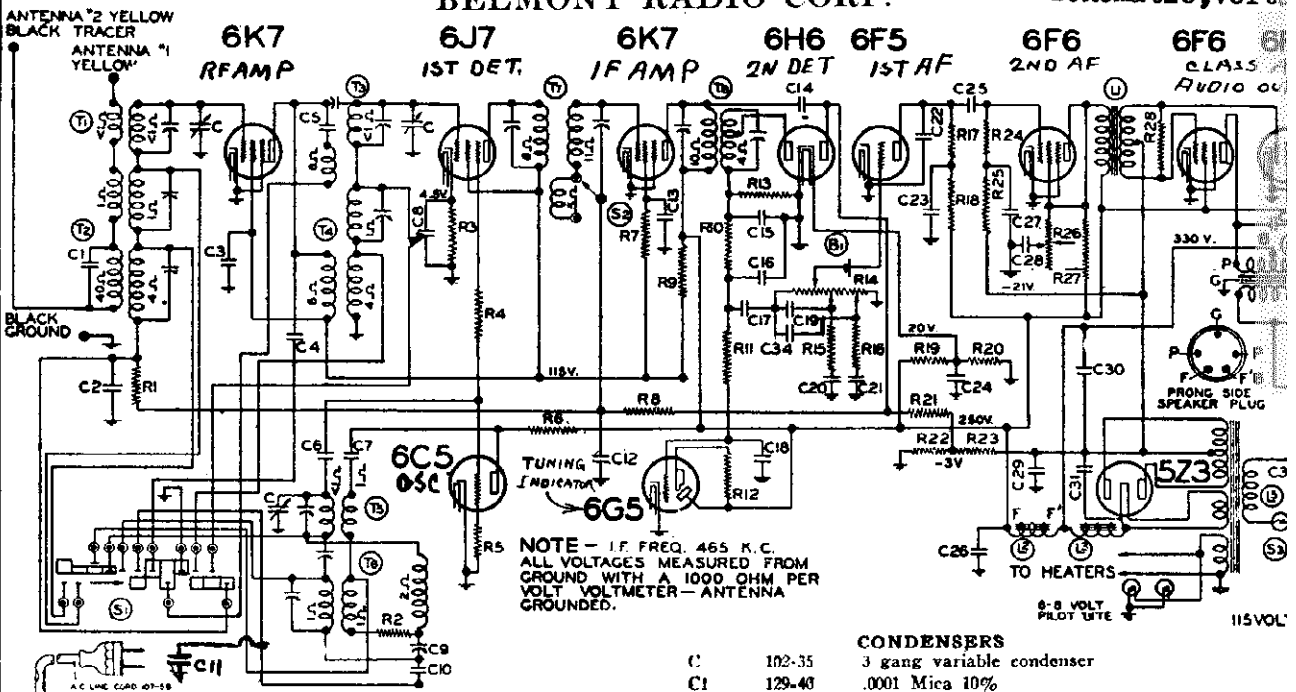

1690 to 5300 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - (a) Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.
 - (b) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. middle wave adjustments.

MODEL 1174

Alignment

BELMONT RADIO CORP.

Service Data for Service Men

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a voltmeter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

ALIGNING INSTRUCTIONS:

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adaptor between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of the multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view Fig. 3).

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.
- With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
- With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

- With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the antenna and ground leads, make the following adjustments:
 - Move dial pointer to 17 megacycles and adjust short wave oscillator trimmer (adjustment number 1) to resonance.
 - Adjust short wave R.F. trimmer (adjustment number 8), and short wave antenna trimmer (adjustment number 9), to resonance.
 - Re-set external oscillator and check set at 18.1 megacycles and 6 megacycles for band coverage and sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 17 megacycle signal can be tuned in not only at 17 on the dial but also at approximately 16.1 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1695 to 5500 Kilocycles

- With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 megacycles and connected in series with "Dummy 3" to the antenna and ground leads make the following adjustments:
 - Move dial pointer to 5 megacycles and adjust middle wave oscillator trimmer (adjustment number 2) to resonance.
 - Adjust middle wave R.F. trimmer (adjustment number 10), and middle wave antenna trimmer (adjustment number 5), to resonance.
 - Re-set external oscillator and check sensitivity at 1800 kilocycles.

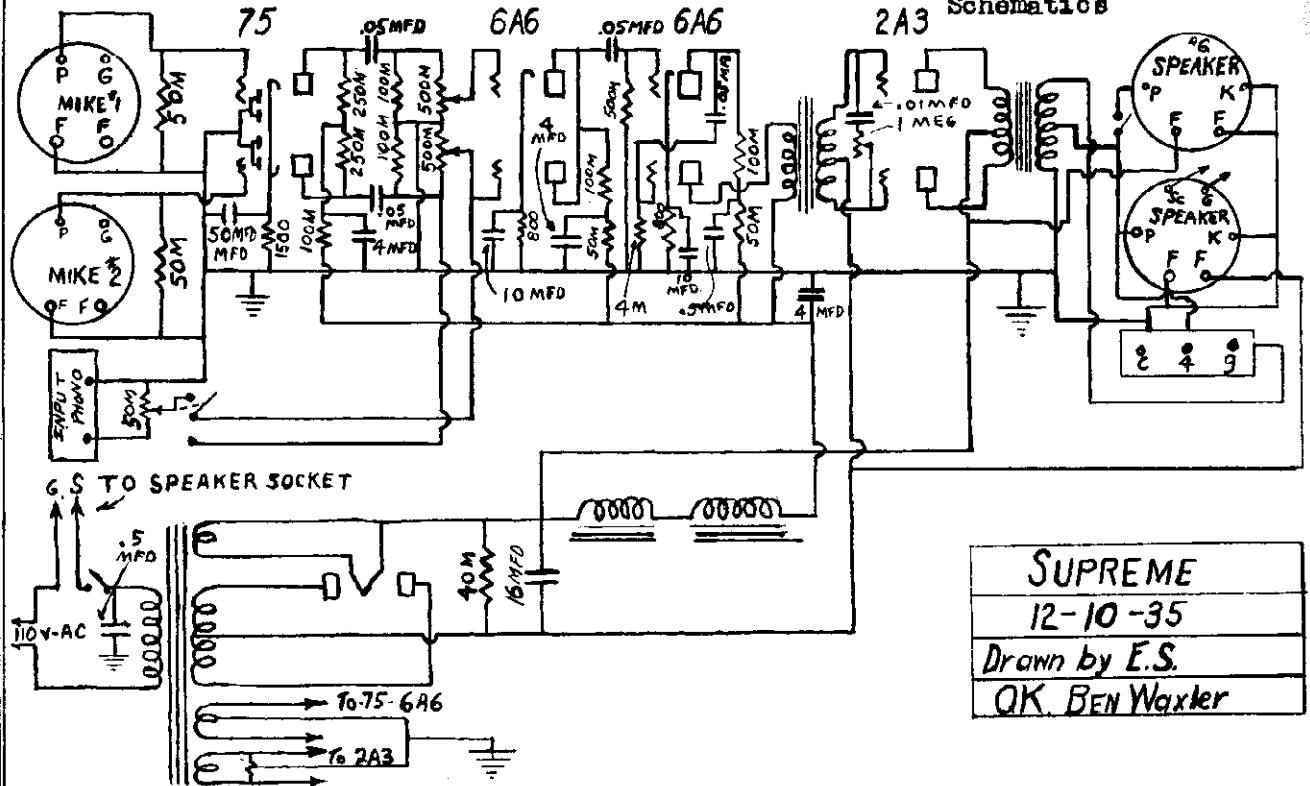

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

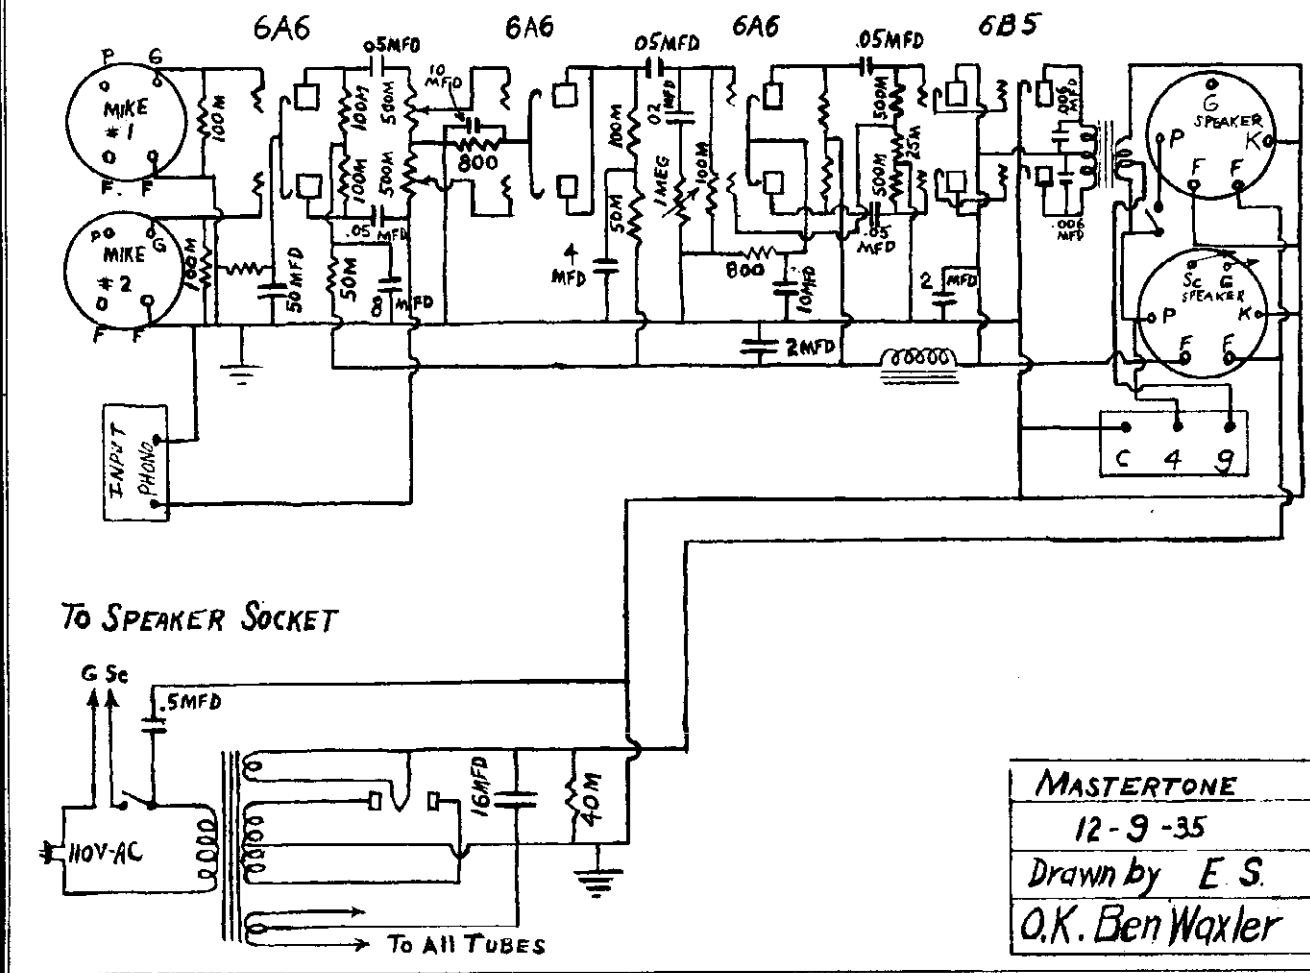

- With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground leads make following adjustments:
 - Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 4; see bottom view of coil assembly, Fig. 3)
 - Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast R.F. trimmer (adjustment number 6) and broadcast antenna trimmer (adjustment number 7), to resonance
 - Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 3) to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
 - Repeat adjustments "a" and "b" until sensitivity is at its maximum.
 - Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.
 - Recheck short wave and middle wave band alignment

MODEL 2SC Communicator
Schematic, Data
MODEL 5SC Communo-Phone
Schematic

**INSTRUCTIONS FOR MODEL 2SC**

The two station Supreme Communicator consists of two units. The master station is unit #1 and the extension station is unit #2. The master uses two tubes: 1-12A7 and 1-6J7. A three wire cable is used to inter-connect the units. The master unit is connected to the power line. The communicator works equally as well on A.C. or D.C., 110 volts.

CONNECTIONS:-

The three terminal strip located on the rear of each unit is used to inter-connect the units. The three wires are connected in numerical sequence, i.e. - 1 to 1, 2 to 2, 3 to 3. The line cord incorporates a self contained resistor, hence, must not be tampered with. The line plug is inserted in any source of 110 volts A.C. or D.C.. In D.C. operation, if the system fails to operate, reverse the polarity by removing the plug from the receptacle, giving it a half turn, and reinserting. On A.C., if a hum is noticed, reverse plug as explained above.

CONTROLS:-

Master Unit - The switch located on the front panel at the left, controls the power for both units, and is put on or off as denoted by the on-off plate. In the center of each unit there is a plate marked "RELEASE TO LISTEN" and "PRESS TO TALK". Conversation is started by pressing the switch down and is held down while talking. When through talking, release and the switch will automatically come back to "RELEASE TO LISTEN" position. Then, the second party will push the switch and talk. This operation is repeated.

REMARKS:-

This amplifier is licensed by agreement with Electrical Research Products, Inc., under patents owned or controlled by Western Electric Co., and American Telephone and Telegraph Co.

CAUTION:-

Do not use any ground or let any of the connecting wires touch any ground, such as water or gas pipes or metal ceilings, etc.

MODEL 5SC Communo-Phone
Instructions

DAVID BOGEN CO., INC.

INSTRUCTIONS FOR MODEL 5SC

The Supreme Communo-Phone is a self powered combination microphone loud speaker system. It operates on either A.C. or D.C. current, 105-125 volts. Each unit draws 35 watts and is designed for continuous service. The tubes used are:- 1-25Z6, 1-6J7, 1-6C5, 1-25A6, and 1-25 watt, 120 volt bulb.

The simplest inter-communication system consists of two of these units connecting one office to a second and permitting instantaneous communication. These units may be combined into a more elaborate inter-communication system by using any number of units up to five. The standard Supreme Communicator is equipped with all the switches and a socket so that a five way system may be connected with a minimum of time and difficulty and without the necessity of additional equipment other than the cable and connector box.

System units with a selection of more than five stations can be supplied in accordance with specified requirements.

CONNECTIONS:-

These units are connected together by means of the Supreme Communicator connector box. Cables are supplied in any length to meet requirements and come equipped with a six prong male plug on each end. The connector box is supplied with a five foot length of cable and a six prong male plug. The cable from the connector box is plugged into the socket marked "A" (see Fig. #1) located on the rear of the first station. To connect the other stations insert one plug of the cable into the socket on the rear of the station, and insert the other plug into a socket on the connector box (see Fig. #2). When less than five stations are used the cables should be plugged into consecutive sockets on the connector box.

Insert the plugs of the line cords into any source of 110 Volt A.C. or D.C. Snap the line switches on and observe the 25 watt lamp. If the lamp is brilliant, reverse the line plug which will give the correct operating polarity. With each unit at correct polarity, the system should be operating. As a check, the line cord should grow slightly warm in operation. Do not attempt to shorten this line cord since the operation of the set is dependent upon a self-contained resistor in it. If you desire to connect your own connector box and cables - refer to figure #3.

WHEN USING THESE UNITS ON D.C.:-

When all units are plugged in as outlined above, inter-communication may be started among the various stations, making sure that the volume control is turned up. If no sound is heard, the polarity of the units is incorrect and all the plugs must be reversed at the same time. This applied to D.C. only.

NOTE:- Do not under any circumstances connect a ground to the chassis.

CONTROLS:-

On the panel there are four momentary contact switches, two on each side of the power switch. Each switch is a selector calling another unit or station. All call switches are normally set in the up or listening position. To call another station, press the appropriate switch down and talk. To listen, release the switch. In setting up this system, it may be found that the volume of voice at the listening end is insufficient for efficient operation. To adjust the volume of the loudness use the screwdriver control adjustment on the rear ("B" Fig. #1).

A headset may be used if it is undesirable to have others, who may be standing near the station, hear the conversation. A magnetic headset should be used with an ordinary phone plug which can be inserted in the jack on the rear panel ("C" Fig. #1). The names of the stations can be assigned to the respective switches by writing in the name. For new names remove the name plate, by taking off five nuts, and insert new paper.

The Supreme Communicator should be used at a distance of arm's length from the unit so as to prevent uncomfortable loud speech at the receiving end.

The person speaking should not raise his voice over that used in ordinary conversation since the Supreme communicator is designed to have enough sensitivity to pick up low voices of moderate distances.

One of the useful features obtainable with the Supreme Communicator System is the possibility of instantaneous call to all stations by pressing all the switches down, whereupon, all other stations listen to the master station. Any unit can become a master to call any number of stations at once.

It is possible for any station to speak to the listening station, although the latter is listening to another station. The station breaking in cannot, however, eavesdrop on any conversation not being directed to him.

Another feature obtainable with the 5-Way Supreme Communicator System is that any two stations can talk to each other, while two other stations are talking without interfering with each other. In other words, each two units comprise a voice channel very much like a telephone switchboard.

NOTE: CAUTION - DO NOT UNDER ANY CIRCUMSTANCE CONNECT A GROUND TO THIS CHASSIS.

REMARKS:

This amplifier is licensed by agreement with Electrical Research Products, Inc., under patents owned or controlled by Western Electric Co., and American Telephone and Telegraph Co. -

DAVID BOGEN CO., INC.

MODEL 2W CommunoPhone
Schematic, Data

The model 2W Bogen Wireless Communo-Phone is an intercommunicating telephone system using the usual power lines both for power and to carry the voice currents. Two or more stations may be operated, but since this model is not selective, all stations will hear all conversations.

Talk-Listen: The knob in the center of the front panel controls the direction of conversation. It normally holds itself in the "Listen" position. To call the other station, depress the knob and speak. Release knob to hear the response from the answering station. The person at the remote or called station must depress his own "Talk" knob before speaking.

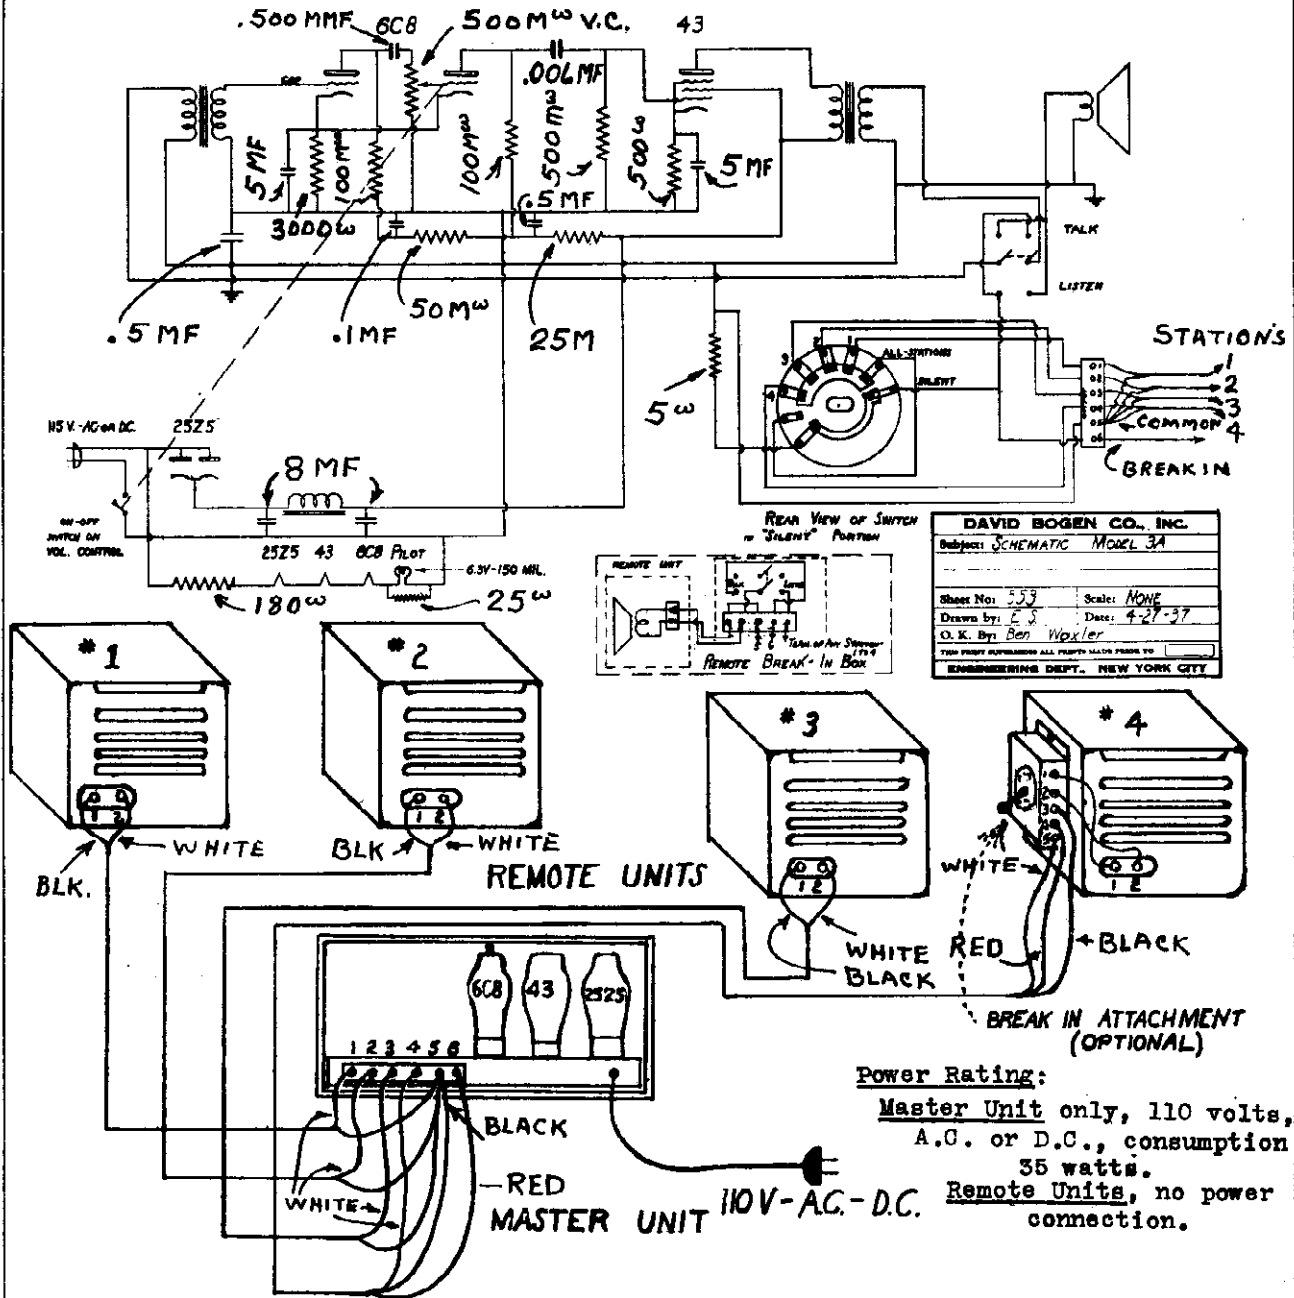

Connections: Insert the attachment cord plug from each unit into the nearest electrical outlet of proper voltage. There are no other connections to make unless the two electrical outlets used are wired on opposite sides of the common ground. In this case the two circuits should be bridged at the fuse box or meter with a paper condenser of a capacity of about 1 mfd. 400 volts. The two "hot" or ungrounded wires are joined thru the condenser as shown in figure 1.

Adjustments: These units are adjusted at the factory to match each other. However if there is reason to attempt to improve the match between the stations, the trimmer condenser screw located on the rear of the chassis may be adjusted. Turn the screw slightly left or right until the best results are observed as determined by the volume and quality of the received voice.

Noise: Some electrical devices such as small motors, flashing signs, oil burners, etc. radiate "man made static" which in some locations causes considerable annoyance to radio listeners and may cause a similar disturbance in the Wireless Communo-Phone. If the source of the noise can be determined, it can be reduced or entirely eliminated by the use of condensers or noise filters on the device creating the noise.

MODEL 3A CommuPhone
Schematic, Data

DAVID BOGEN CO., INC.

Power Rating:
Master Unit only, 110 volts, A.C. or D.C., consumption 35 watts.
Remote Units, no power connection.

The model 3A Bogen Selective Commu-Phone provides selective communication between the Master Station and one to four Remote Stations.

Connections: Using a two wire cable connect all the Remote Units so that their #1 terminals connect to #5 on the Master Unit. Then the remaining wire from each Remote Unit (Terminal #2) connects to its own selective terminal numbered 1, 2, 3 or 4 on the Master Unit. Plug line cord into the usual power outlet. If the device is silent when first connected to Direct Current the power line plug should be removed and rotated so that its prongs are reversed - this is done to correct the polarity.

Station Selector: The center knob is used to select the station called. It may be set to communicate with any single Remote Station or to call all at once. It is normally left in the "Silent" position. The Master Station can listen-in on any or all Remote Stations without warning.

Talk-Listen: The lower knob automatically remains in the "Listen" position. When it is desired to speak from the Master Station the knob is pressed down to the "Talk" position. It must be released to hear the reply from the station called. Because of the sensitivity of the Remote Units it is not necessary for the person called to approach the box closer than about 20 feet, thus saving steps and interruption of work. The Remote Stations can only "Talk" or "Listen" when the Master Switch is properly set.

DAVID BOGEN CO., INC.

- is supplied with each amplifier and is connected as follows:-
1. Skin outer rubber covering about 3/8" exposing the shield.
 2. Remove all cotton sleeving which in some cable is present over the metal shield and insert over the shield the metal sleeve supplied with the connector.
 3. Remove the exposed shielding up to the sleeve making sure to bend back over the sleeve all loose metal wires.
 4. Skin second rubber covering about 1/8" from the sleeve exposing about 1/4" of the conductor.
 5. Insert the cable thus prepared into one part of the connector, drop the spring washer in the recess, place bakelite washer over it allowing the conductor to pass through eyelet.
 6. Clean and solder conductor to eyelet, cut excessive wire, and screw set screw over the sleeve.
 7. Do not use soldering paste or acid on any connection on microphone or cable.

OUTPUT CONNECTIONS:-

Two, one thousand ohm speakers must be connected to the amplifier by means of sockets marked "SP" located on the right side of the amplifier. As a safety measure, these sockets are so wired that the A.C. to the amplifier is cut off unless both speaker plugs are inserted. The speakers are wired as shown in Fig. 1. Additional speakers having their own source of field supply may be connected by using the taps on the strip marked "OUTPUT". The terminal connections are as follows: Terminal #1 is common; #2 is four ohms; #3 is nine ohms; #4 is fifteen ohms and #5 is five hundred ohms.

A.C. RECEPTACLE:-

An A.C. receptacle is located on the rear panel. This can be used to connect the A.C. for additional speaker excitors, phonographs, etc. The A.C. to this outlet is controlled by the master switch on the front panel.

FIELD SUPPLY:-

The built-in field supply will furnish 100 mils. at 125 volts to each of two 1000 ohm speakers. This field supply is not taken from the plate voltage supply but has its own source of power.

FUSE:-

If the amplifier fails to operate when turned on, examine the fuse clip. A five ampere fuse is used. If this fuse is burned out, examine the connections for a possible short circuit.

CONTROLS:-

Mixer Fader - The first control on the left governs the gain for either channel #1 or #2. With this control it is possible to fade from channel #1, a high gain input to channel #2, a low gain input. The second control from the left governs the gain for either channel #3 or #4 similarly. By using both controls simultaneously it is possible to mix the inputs from channels #1 and #2 with those of channels #3 and #4.

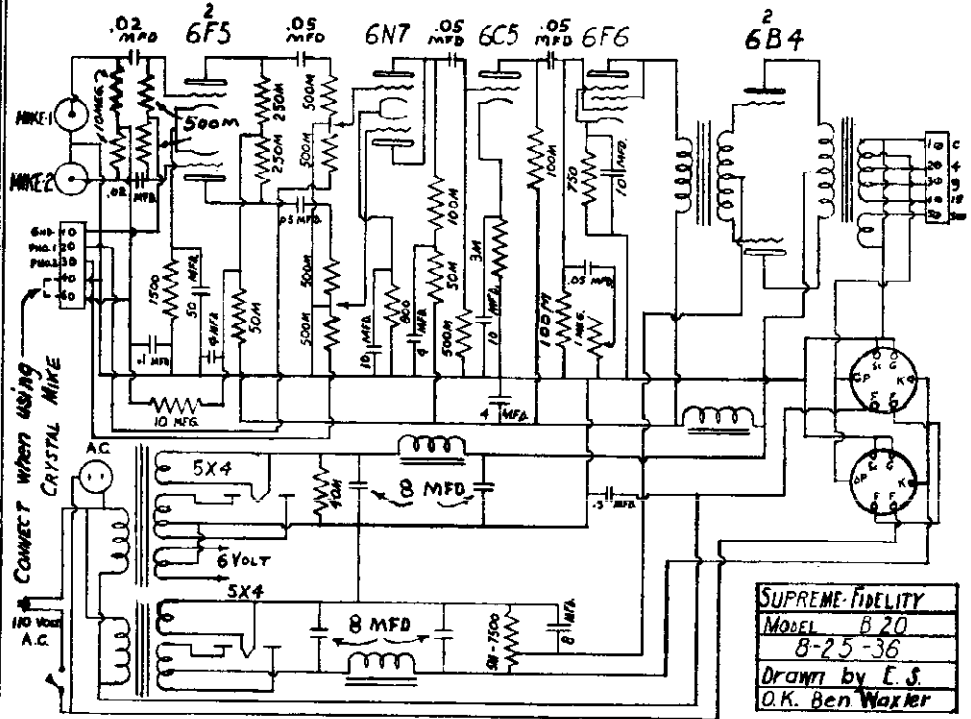

Tone - The control marked "Tone" is used for tone correction effects.

Master Switch - The switch at the extreme right on the control panel controls all A.C. The pilot light indicates when the amplifier is operating.

REMARKS:-

If any hum is noticed, when using the microphone, reverse the line polarity, by pulling out the line plug, giving it a half turn and reinserting.

Hum can be caused by faulty tubes, particularly with a high gain amplifier of this design. Check all tubes carefully before looking elsewhere. In rare cases an external ground may be necessary.

INSTRUCTIONS FOR MODEL B-20

The Supreme Fidelity Model B-20 is a nine tube amplifier operating on 110-125 volts, 50-60 cycles with a drain of 275 watts. The tubes used are: 2-6F5M, 1-6N7, 1-6C5, 1-6F6, 2-6B4, 2-5X4G.

INPUT CONNECTIONS:-

The five post input strip is used as follows: Terminals #1-2 are channel #2 for a phonograph or other low gain input. Terminal #1 is the ground side; terminals #1-3 are channel #4, for another phonograph or low gain input. When using a Crystal microphone connect posts #4 and #5 by a wire. Do not jump these terminals when using a Velotron or Velocity microphone.

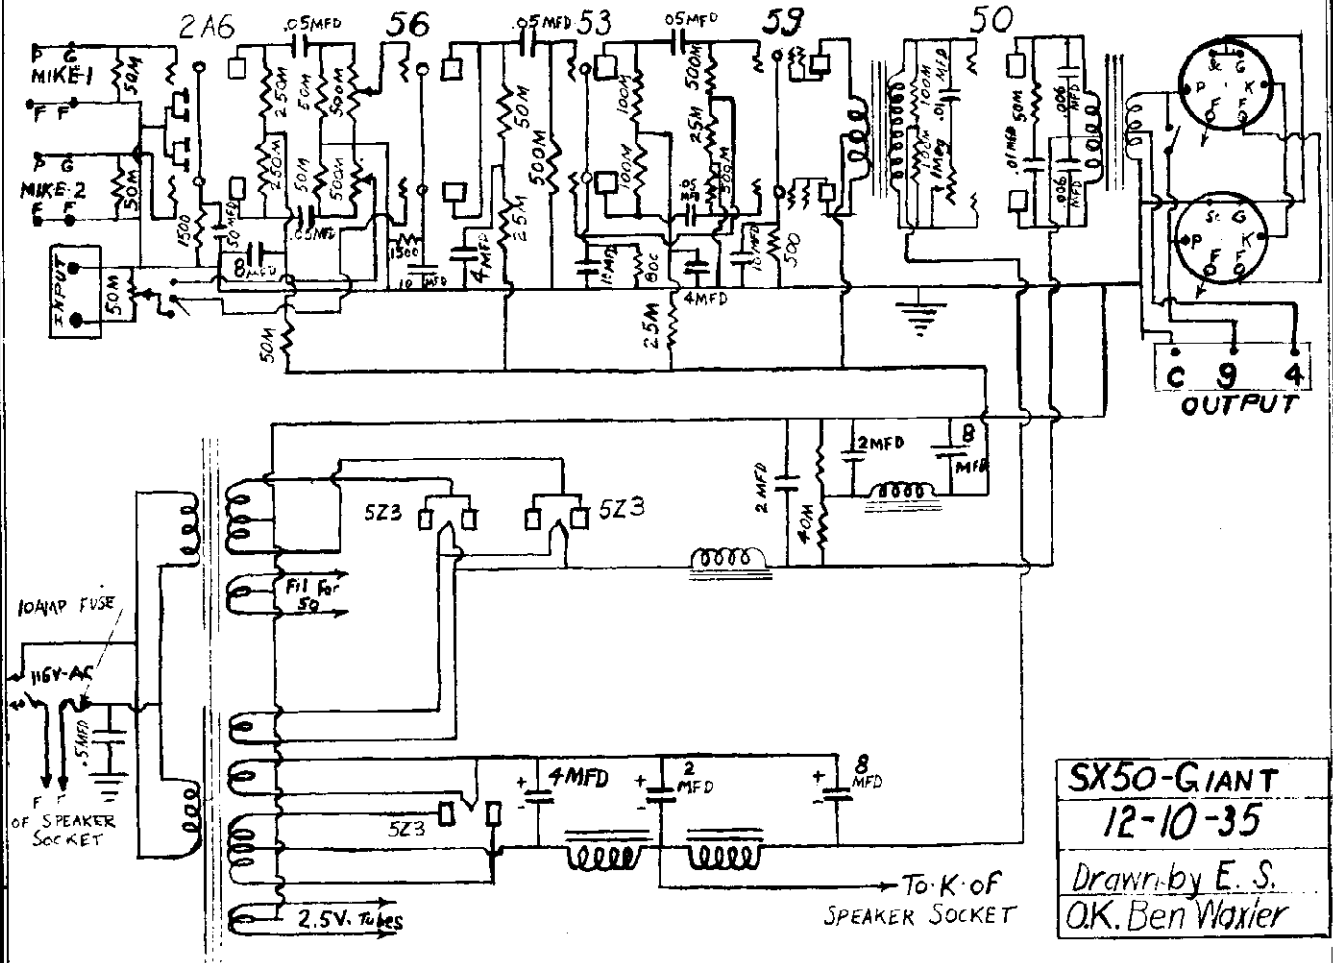

MICROPHONE CONNECTIONS:-

Above the five post strip are two screw cable connectors. These are the two channel inputs #1 and #3, for Velotron, Velocity or Crystal microphones. For each microphone, a single conductor shielded cable must be employed. The plug that is used on the microphone cable

CONNECTIONS

On the left side of the amplifier, there are two sockets marked "MIKE #1" and "MIKE # 2". One or two microphones can be connected to the amplifier by plugging into these sockets. For microphone connections see Fig.1. Shielded cable and plug must be used between the amplifier and the microphone. The metal cover of the plug must be used between the amplifier and the microphone. The metal cover of the plug must be grounded to the shield as shown in Fig.1.

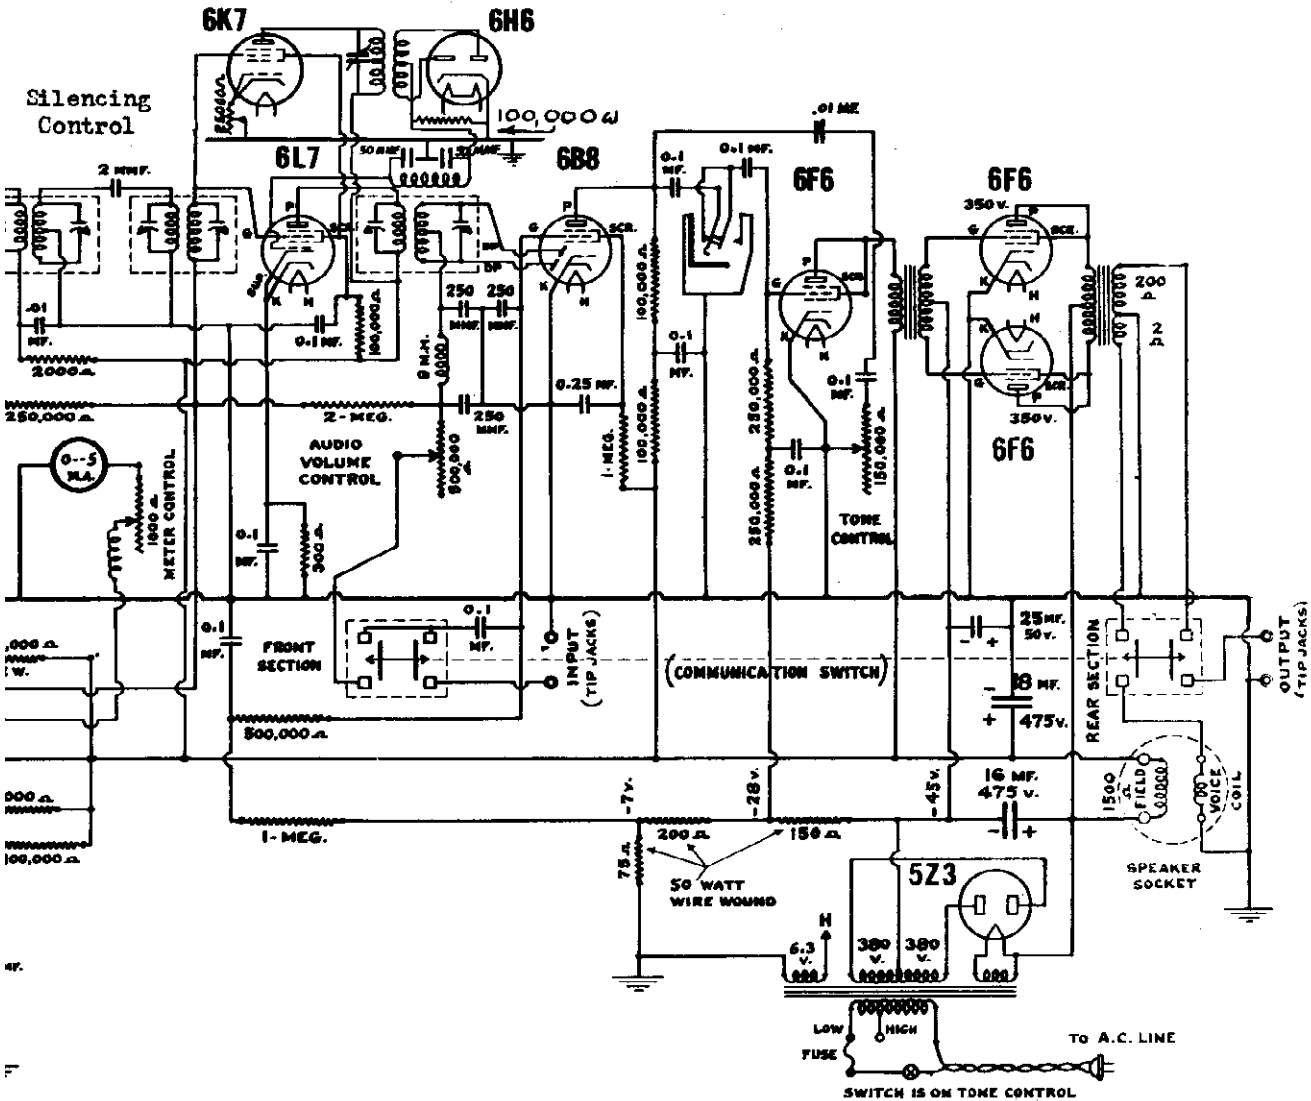

On this same side there is a tip jack marked "PHONO". This jack is used to connect phonographs having tip connectors. Above this jack is a two terminal strip marked "INPUT". These terminals can be used for various input connections such as any low gain input, phonograph, or microphone (dynamic), or radio. The jack and input strip are controlled by the # 3 control.

On the right side of the amplifier there are two six prong sockets marked "SPEAKER". These sockets are used to connect the two speakers required by the amplifier. For the speaker plug connections see Fig.2. The built-in field supply will furnish 100 mils, at 125 volts to each speaker. This field supply is not taken from the plate voltage supply, but has its own poer supply. A three terminal output strip marked C-4-9, is located at the right of the speaker sockets. These terminals can be used to match the voice coils of any additional speakers. Additional speakers must have their on source of field supply, either built in or external.

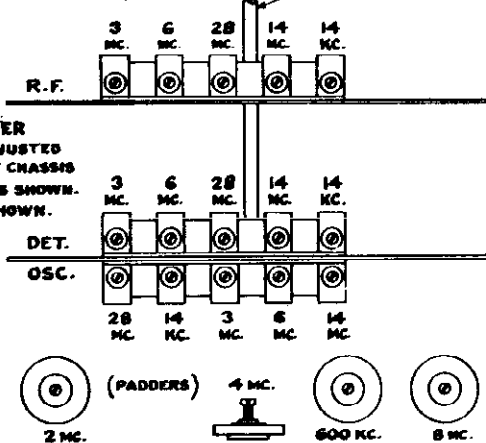

MODEL 14
Alignment, Notes

ANTENNA: To insure best results it is absolutely essential that a first-class antenna be used. We recommend a single solid wire, 50-75 feet in length, including lead-in. Height over any obstruction in the immediate vicinity is, of course, highly desirable, and should be obtained whenever possible. An ideal situation with respect to antenna would be the use of two or three antennas running in different directions and using a switch mounted near the radio. This procedure would enable the operator to select the antenna giving the best results in any particular location.

On the higher frequencies a short antenna will usually give better results, and on the 10 meter band a 16 ft. vertical generally proves most efficient.

The only advantage obtained in using a doublet antenna would be to locate the antenna pick-up portion out of a noisy field, such as is usually found in a location near a street car line or much traveled highway. In locations of this kind the antenna proper can be located as far away as possible from the disturbing factor, and the long lead-in can be brought to the receiver without a great amount of loss. Almost all commercially made doublets are furnished with the matching transformer equipped with electro-static shields to eliminate any capacity pick-up in the lead-in. There are many coupling transformers on the market that may be obtained by anyone who desires to construct their own doublet, but when this is done a matching transformer should be used that is equipped with electro-static shield.

NOISE SILENCER CONTROL: The noise silencer is equipped with a filament switch that turns the two noise silencer tubes off when in the extreme left position. To operate the silencer the control should be turned to the right, and after the tubes have had sufficient time to heat advancing the control will cause the set to block when a station is tuned in. The point of operation is very critical and just below the blocking point. The weaker the signal the more effective becomes the noise silencer. It is worthless on a strong signal and on certain types of noise. The silencer cannot be used on local or extremely strong signals. The silencer is not a cure-all for static generally speaking, but it is very efficient in eliminating certain types of interference.

COMMUNICATION SWITCH: The communication switch disconnects the audio amplifier from the radio and connects it to the tip jacks on the rear of the chassis. The middle terminals on rear of chassis are connected to the 200 ohm line, the bottom one of which is grounded to the chassis. The terminals nearest the speaker plug when opened break the B+ to the RF portion of the receiver. Needless to say, these terminals are hot with respect to the chassis. The audio amplifier

will drive any type of final amplifier, and if used as a modulator, will modulate approximately 100 watts. When using the receiver as a modulator, a modulation transformer with a 200 ohm primary and a secondary with a correct load to match the transmitter must be used. Numerous speaker transformers when reversed will operate satisfactorily for this purpose and several manufacturers have special transformers expressly made for this service, such as Inca Models N18 and N17.

A large number of amateurs are modulating at speech frequencies, 100W transmitters. In case feed back difficulties are encountered, try reversing connections on the external transformers and shielding all connecting wires. Sometimes a separate switch on the B+ terminals will be necessary while transmitting. A microphone transformer and volume control will be necessary for high level carbon microphones, and a high gain preamplifier is necessary for low level microphones. A single high gain stage is generally sufficient for the diaphragm type crystal microphones.

The filament and plate power for the preamplifier stage can be supplied by the receiver. On rotary type communication switch extra terminals are supplied to turn transmitter on with the communication switch.

CRYSTAL PHASING CONDENSER: To obtain results with the crystal circuit, a complete understanding of crystal selectivity must be had by the operator.

Let us consider the ordinary C. W. signal as received by a super with the crystal in the off position. The band width of the carrier is about 10,000 cycles and is heard as a series of dot and dash hissing sounds as the receiver is tuned thru the range of the 10,000 cycles. If the beat oscillator is turned on and adjusted when the dial is set to the center of the carrier, you will notice that the C. W. signal becomes a howl and the pitch varies as the beat oscillator adjustment is turned from one side to the other. It starts as an extremely high pitch howl down to a zero beat point and then up the other side until the pitch becomes so high it is lost to the ears.

Now set the beat oscillator until a 1,000 cycle note is heard. Next adjust the crystal trimmer until the background noise is at minimum and a ringing sound is heard in the speaker. The C. W. signal will probably have been lost during this operation and the main dial will have to be readjusted until you find the narrow peak of the signal.

Remember that the peak of the crystal is only 50 cycles wide compared to 10,000 cycles without crystal. You can understand by comparing the above figures why the average amateur never finds the C. W. peak on the crystal and is ready to condemn its performance. The signal strength should not change as the trimmer is turned from the left hand off position to the right hand position.

Greatest selectivity of the crystal will be found as the trimmer is turned about two-thirds of the way to the right. If the signal strength changes as the trimmer is adjusted, the signal is not tuned in on the peak or else the beat oscillator is not adjusted 1,000 cycles to one side of zero beat. Different degrees of selectivity can be obtained on C. W. by not bringing the crystal trimmer in exact phase. The broad positions are on either side of where minimum noise is heard.

For phone reception leave beat oscillator off and keep crystal in either position. At best the reception will be poor.

On C. W. turn the volume control three-quarters on and use the manual control to bring up the signal level. Do not advance it too far on the crystal as it will overload the first detector and motor booting will result.

BEAT FREQUENCY OSCILLATOR SWITCH: The beat oscillator control turns the R meter off and converts the vacuum tube volt meter tube into a beat oscillator. It also shorts out the AVC circuit requiring the manual volume control to be turned to the left to keep from blocking the receiver.

To locate weak stations, turn beat oscillator switch to the right. This should produce a hissing sound in the speaker, and as the tuning dial is rotated, all stations will be heard with a definite squeal. After locating station, retune to greatest volume.

Adjust beat oscillator by turning the condenser shaft extending through the bottom front, left corner until the desired pitch is obtained. To make the beat oscillator adjustable from the front panel solder a heavy wire or handle to the shaft and allow it to extend out under the base pan.

RF GAIN CONTROL OR MANUAL VOLUME CONTROL: The RF gain control is used for code reception and should be rotated to the left when silent tuning is desired.

R METER ADJUSTMENT: To adjust the R meter, disconnect the antenna, and after the receiver has been on a few minutes, turn the control marked "R" METER ADJUSTMENT until the pointer swings to the maximum left hand position. The meter is at ground potential and cannot be damaged except through rough handling in a mechanical way.

ANTENNA TRIMMER ADJUSTMENT: Adjust the antenna trimmer on any station around 14 megacycles. Turn adjusting screw carefully until greatest signal strength is shown on the R meter. DO NOT ADJUST ANY OTHER TRIMMERS. The trimmer is adjusted correctly at the factory and should not require over 1/2 turn in either direction.

ALIGNMENT PROCEDURE

Tune the Intermediate Frequency transformers to resonant point of Crystal. This point may be 200 to 1000 cycles different from the oscillating point of the crystal (if crystal was used as oscillator control). Adjust IF transformers in following sequence :-

- (1) Align the 2nd Detector stage.
- (2) Band-pass IF stage located in center of chassis.
- (3) Crystal grid coil.
- (4) 1st Detector plate coil (On rear of chassis)

Place crystal in the filter circuit, tune in a low frequency broadcast station of 600 KC, adjust sensitivity control until "R" meter reads R6. Then phase crystal and retune dial to minimum modulation and maximum R strength location. Turn crystal off, without disturbing dial, retune IF trimmers as before to greatest "R" strength. Next align crystal resonant point with the IF. Crystal oscillator not necessary if IF adjustments have not been disturbed.

To adjust Low Frequency of each band. Trimmers are located on top of chassis, 75 meter trimmer located on the rear. High frequency trimmers are located on coil switch. At most trimmers should not require more than 1/8 turn for correction.

If variable condenser plates have become bent, realign rear unit of the three double sections of variable condenser, using 20 to 40 meter band as a standard. The broadcast portion of variable condenser is located in front unit of the 3 double sections of variable condenser, and plates can be bent slightly for maximum gain and correct alignment when set is used on different antennas.

The oscillator section is located in rear double gang. In case the gear has slipped on condenser shaft or the belt damaged, set pointer at 580 KC when the condenser plates are even with front of condenser frame. This can be checked by laying knife along frame, opening the variable until rotor plates touch the knife. The pointer should be within 2 KC of 580 KC. For greater variations loosen gear on the condenser and slide rotors.

Alignment, Notes

CADILLAC MOTOR CAR CO.

Calibrating the Radio

Tune in a signal of known frequency at about the center of the dial. Choose a station with a frequency which corresponds to one of the numbers on the dial drum. For example, WLW, with a frequency of 700 KC, corresponds to 70 on the dial.

Hold the tuning knob. Using a clean eraser on the end of a lead pencil, turn the dial drum until the frequency of the station tuned in is at the center of the dial opening.

Inserting Antenna Plug

IMPORTANT—The antenna plug can be inserted in two ways depending on whether the antenna is of high or low capacity.

Referring to Fig. 3, it will be noted that the letters HC and LC are stamped on the case. There is a spot of paint on the antenna plug. When the plug is inserted with the spot of paint on the LC side, it is properly inserted for a high capacity antenna and when it is inserted with the spot of paint on the HC side, it is properly inserted for a low capacity antenna.

If the total capacity of the antenna and shielded lead is approximately 300 mmf., which would be the case in a running board or ordinary roof antenna (not metal roof), insert the antenna plug for a high capacity antenna or with the mark on the LC side.

If the total capacity of the antenna and shielded lead is approximately 70 mmf., such as may be the case if a "fish pole" antenna is used, insert the antenna plug for a low capacity antenna or with the mark on the HC side.

1400 KC Adjustment

Set the signal generator for 1400 KC. Turn the rotor of the tuning condenser, carefully until maximum output is obtained. Adjust the 1st det. and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained.

Adjust the antenna 600 KC trimmer to maximum. This trimmer is reached from the outside of the case. See Fig. 3.

After the alignment procedure is completed, the antenna plug may be withdrawn and re-inserted for a low capacity antenna (mark on HC side) if a low capacity car antenna is used.

Adjusting Antenna 600 KC Trimmer

After the radio is installed and the car antenna is connected, it will be necessary to readjust the antenna 600 KC trimmer.

Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 3 for location of this trimmer.

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the 1st det. section of the tuning condenser. (See Fig. 2. for location of this section.)

Connect the ground lead of the signal generator to the chassis. The chassis should be in the "Distance" position and keep it in this position for all adjustments.

Set the volume control at the maximum position. Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1581 KC Adjustment

Set the signal generator for 1581 KC. Turn the rotor of the tuning condenser to the full open position.

Insert the antenna plug for a high capacity antenna (mark on LC side). Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—See Fig. 2 for location of this trimmer.

MODEL 6R

Alignment, Voltage

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the antenna lead of the signal generator thru a .05 mf. condenser to the stator of the 1st detector section of this section. (See Fig. 2 for location of this section.) This can be done by pushing a wire or conductor between the stator plates or by extending an insulated wire thru the hole in the shield over the stator and pushing the wire thru the hole in the lug which extends up from the insulated stator assembly.

Connect the ground lead of the signal generator to the chassis ground.

Short out the oscillator section of the tuning condenser.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1650 KC. Adjustment

Set the signal generator for 1650 KC.

Turn the rotor of the tuning condenser to the full open position.

Connect the shielded antenna lead from the chassis through a 150 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC. Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC. with the volume control about three-fourths on. Remove the cover of the chassis case. The antenna trimmer is on the center tuning condenser section—see Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

MODEL 68

Alignment, Voltage Socket, Trimmers

Changes, Notes

- Power Output - 3 Watts Maximum
- Sensitivity - 1.5 Microvolts Absolute
- Frequency Range - 530 to 1650 KC

CADILLAC MOTOR CAR CO.

- Speaker - 6 Inch Dynamic
- Power Consumption - 5.75 Amperes at 6 Volts
- I. F. - 175 KC

I. F. Adjustment

- Remove chassis from case.
- Establish ground connection between chassis and power supply.
- Reconnect A and B wires from power supply to chassis.
- Set the signal generator for a signal of 175 KC.
- Connect the antenna lead of the signal generator thru a .05 mf. condenser to the stator of the 1st detector (middle) section of the tuning condenser. This can be done by pushing a wire or conductor between the stator plates or by extending an insulated wire thru the hole in the shield over the stator and pushing the wire thru the hole in the lug which extends up from the insulated stator assembly.
- Connect the ground lead of the signal generator to the chassis ground.
- Short out the oscillator section of the tuning condenser.
- Set the volume control at the maximum position.
- Attenuate the signal from the signal generator to prevent the levelling off action of the A.V.C.
- Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers are shown in Fig. 2.

1650 KC. Adjustment

- Set the signal generator for 1650 KC.
- Turn the rotor of the tuning condenser to the full open position.
- Connect the shielded antenna lead from the chassis through a 250 mmf. condenser to the antenna post of the signal generator.
- For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A. V. C. action.
- Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 K C. Adjustment

- Set the signal generator for 1400 KC.
- Turn the rotor of the tuning condenser carefully until maximum output is obtained.
- Adjust the 1st detector and antenna trimmers for maximum output.
- Do not change the setting of the oscillator trimmer.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC. with the volume control about three-fourths on. Remove the cover of the chassis case. The antenna trimmer is the trimmer condenser closest to the terminal strip—see Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Calibrating the Receiver

After installing the receiver in the car the control unit or flexible shaft will probably cause the setting of the dial pointer to change. The receiver may then be recalibrated as follows: Tune in a station of known frequency at about the center of the dial. Then loosen the set screw which secures the station selector knob to the shaft.

The station selector shaft is made up of two sections—an inner and an outer shaft. By loosening the set screw in the station selector knob one turn, the knob and the outer shaft are disengaged from the inner shaft. The inner shaft is directly connected to the tuning condenser in the chassis.

By turning the station selector knob it will be found that the dial scale can be adjusted without disturbing the tuning of the receiver. Turn the knob until the dial scale is exactly at the frequency of the station which has been tuned in.

Retighten the set screw in the station selector knob.

Circuit

The circuit consists of a 6D6 R.F. stage, a 6C6 1st detector-oscillator stage, a 6D6 I.F. stage, a 75 dual diode-triode tube, which functions as a diode 2nd-detector and a triode 1st audio stage, and a single 41 output stage. An 84 full wave rectifier is used in the power unit. The intermediate frequency is 175 KC. The diode current establishes a drop across a resistor which is used as additional bias voltage for the R.F. and I.F. tubes giving automatic volume control action. The manual volume control varies the audio voltage to the grid of the 75 tube.

Changes In Early Models

In the early models, resistor R14, and condenser C30, were not used. In these models resistor R11 was rated at 200,000 ohms. The capacity range of the 1st I.F. Trimmer Condensers C9 and C10, was from 130 to 300 mmf. in the early models.

MODEL 61
Schematic, Motor

Power Output - 8 Watts Maximum
Sensitivity - 1.5 Microvolts Absolute
Frequency Range - 530 to 1650 KC
Size of Speaker - 8" and 10"
Field Resistance - 5.4 Ohms (hot)

Power Consumption - at 6 Volts
Chassis - - - - 2.3 Amperes
Genemotor - - - 3.5 Amperes
Speaker Field - - 1.1 Amperes
Pilot Light - - - 0.1 Amperes
TOTAL - - - - 7.0 Amperes

Genemotor Assembly
The genemotor assembly contains all of the parts shown within the dotted lines in Fig. 4. We do not recommend that the genemotor itself be serviced in the field. The filter unit associated with the genemotor may be checked and any defective parts repaired or replaced. However, if the genemotor itself is at fault, it should be sent back to the factory for repair.

The circuit of this receiver consists of a 6D6 R. F. stage, a 6C6 1st detector-oscillator stage, a 6D6 I. F. stage, a 6B7 dual diode-pentode tube, which functions as a diode 2nd-detector and pentode 1st audio stage, and a 42 push pull output stage. A genemotor supplies the high voltage to the receiver. The intermediate frequency is 262.5 KC. The diode current establishes a drop across a resistor (R8) which is used as additional bias voltage for the R. F. and I. F. tubes.

Circuit
NOTE: THE WIRE SHIELD, WAVE COIL AND FIELD RETURN SOLDERED TOGETHER. THE FRAME OF SPEAKER MUST BE ELECTRICALLY CONNECTED TO SHIELD. GROUPS OF CIRCUIT ELEMENTS ENCLOSED IN DOTTED RECTANGLES COMPRISE DISTINCT MECHANICAL ASSEMBLIES. CIRCUIT ELEMENTS ENCLOSED IN DOTTED CIRCLES DO NOT EXIST AS DISTINCT UNITS BUT OCCUR AS A RESULT OF THE MUTUAL POSITION OF OTHER CIRCUIT ELEMENTS OR THEIR PARTS.

MODEL 6T
Alignment, Voltage

Data

CADILLAC MOTOR CAR CO.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the standard wave band and an accurately calibrated signal at 262.5 K. C., the intermediate frequency and an output indicating meter are necessary.

The chassis must be removed from the case.

I. F. Adjustment

Set the signal generator for a signal of 262.5 KC.

Connect the antenna lead of the signal generator thru a .05 mf. condenser to the coil end of the grid leak resistor R2. This connection can be made at either end of the lead between the stator of the 1st detector section of the gang condenser and the interstage R. F. coil.

Connect the ground lead of the signal generator to the chassis ground.

Short out the oscillator section of the tuning condenser. Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling off action of the A. V. C.

Then adjust the three I. F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the back of the chassis - see Fig. 1.

CAUTION:—Use an insulated screwdriver for adjusting these trimmers to prevent short circuiting to ground.

1650 KC. Adjustment

Set the signal generator for 1650 KC.

Turn the rotor of the tuning condenser to the full open position.

Connect the shielded antenna lead from the chassis through a 250 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A. V. C. action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 4 for location of this trimmer.

1400 KC. Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser until maximum output is obtained.

Adjust the antenna and 1st detector trimmers of the gang condenser for maximum output—see Fig. 4 for location of these trimmers. Do not change the setting of the oscillator trimmer.

Fig. 1—Location of Trimmer Condensers

Fig. 3—Block Condenser

600 KC. Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Use a non-metallic screwdriver for this adjustment.

Turn the rotor slowly back and forth at the same time adjusting the oscillator padding condenser until the peak of greatest intensity is obtained. See Fig. 1 for location of this trimmer.

1400 KC. Adjustment Check

Set the signal generator for 1400 KC.

Check the setting of the antenna and 1st detector trimmers of the gang condenser for maximum output. Do not change the setting of the oscillator trimmer section.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 KC. with the volume control about three-fourths on. The location of the antenna trimmer is shown in Fig. 4. This trimmer may be reached by removing the small metal plate on the end of the chassis case. Turn the adjusting screw of this condenser up or down until maximum output is obtained. **CAUTION:**—Do not turn any of the other trimmer adjusting screws for this adjustment.

Calibrating the Receiver

After reinstalling the receiver in the car the control unit or flexible shaft will probably cause the setting of the dial pointer to change. The receiver may then be recalibrated as follows: Tune in a station of known frequency at about the center of the dial. Then loosen the set screw which secures the station selector knob to the shaft.

The station selector shaft is made up of two sections—an inner and an outer shaft. By loosening the set screw in the station selector knob one turn, the knob and the outer shaft are disengaged from the inner shaft. The inner shaft is directly connected to the tuning condenser in the chassis.

By turning the station selector knob it will be found that the dial scale can be adjusted without disturbing the tuning of the receiver. Turn the knob until the dial scale is exactly at the frequency of the station which has been tuned in.

Retighten the set screw in the station selector knob.

ALIGNMENT PROCEDURE

If at any time it becomes necessary to realign this receiver, the following procedure should be employed: Set pointer so it is perfectly horizontal when the variable condenser is fully engaged. Connect the green antenna lead in series with a 200 mmfd. mica condenser to the output of the signal generator. Connect the black lead to the ground lead of the signal generator. Set the signal generator to 456 K.C. and turn the variable condenser on the receiver until the plates are completely intermeshed. Turn the selector switch to the Broadcast position and set the volume control knob to maximum. Connect an output meter between the plate and screen of the 42 output tube. Adjust trimmers C1, C2, C3 and C4 for maximum output as indicated by the meter. At all times keep the output control on the signal generator turned down as low as possible so as to obtain only a very small reading on the output meter. (At larger inputs the automatic volume control system may tend to obscure the correct adjustment.) Next set the signal generator to 1400 K.C., and turn the dial of the receiver to correspond to that frequency. Adjust trimmer C8 for maximum reading of the output meter and then adjust C6 to secure final adjustment. Next rotate the receiver dial to about 600 K.C. and set the signal generator at the same frequency. Adjust trimmer C7 while rocking the condenser back and forth until maximum output results. If it is necessary to turn that adjustment screw more than about one turn, it will be necessary to repeat the adjustment at 1400 K.C. again. This completes the alignment of the Broadcast band.

LEFT S.W. - RIGHT A.C. BAND SELECTOR SWITCH

ON-OFF SWITCH & VOLUME CONTROL

PILOT LIGHT CONTROL

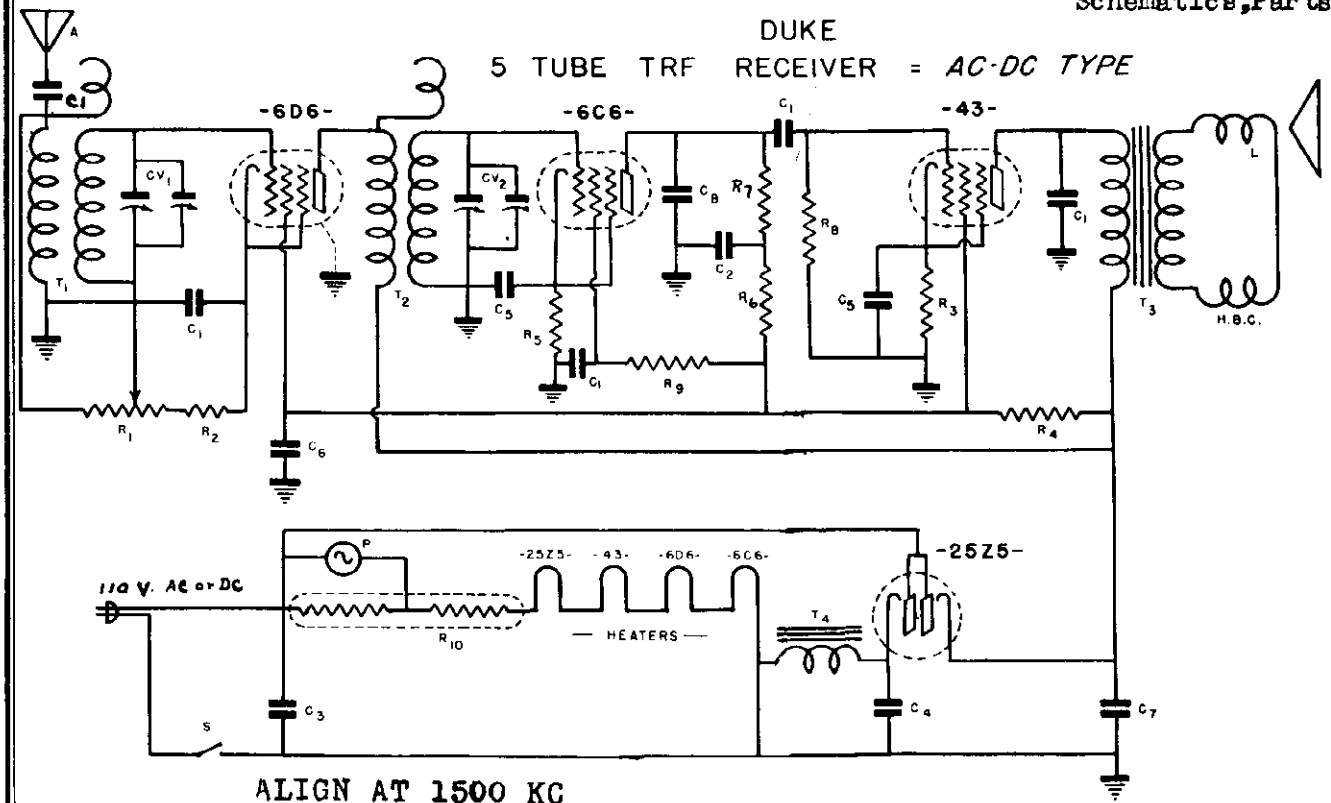

TOP VIEW

Next, substitute a 400 ohm carbon resistor for the series mica condenser between the receiver and the signal generator and set the switch to the short wave position. Rotate the receiver dial to 14M.C. and set the signal generator to the same frequency. Adjust trimmer C5 to resonance and then increase the generator frequency to 14.9M.C. and observe if the signal can be heard without changing the receiver dial setting. If it can be heard, then the image is properly placed and the signal generator should again be set to 14 M.C.. Adjust trimmer C9 for final adjustment.

5M Chassis

This receiver is designed to operate from a power supply main of 110-120 volt, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

ANTENNA
Use a standard outside antenna of at least 50 feet including lead-in. Connect the antenna to the "Blue" lead.

In remote locations that are far away from powerful broadcasting stations, a longer antenna may be used for increased receiving range. Antennas as long as 150 to 200 feet may be employed in "dead spots." (Longer antennas increase sensitivity and decrease selectivity slightly.)

The ground wire should be connected to the "Black" lead.

Six Tube 6 Volt Battery Superheterodyne 6P Chassis ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, and 18,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6D8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** Approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the

same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the antenna. Retune to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

POLICE BAND ALIGNMENT

The police band is adjusted by first replacing the .004 dummy with a 400 ohm resistor and setting the gang to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to get maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit at this frequency as described in the instructions for padding the broadcast circuits.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the gang to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC and adjust the "short wave antenna" to get maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 6D8G (signal and rotor plates of oscillator section on gang condenser). Oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

MODEL 6P Chassis
Socket, Trimmers CONTINENTAL RADIO & TELEV. CORP.
Notes, Parts

tion does not in any way enter the interior of the battery.

ANTENNA

REGULAR ANTENNA Use a standard outside antenna of at least 50 feet including lead-in. Connect the antenna to the "Blue" lead.

In remote locations that are far away from powerful broadcasting stations, a longer antenna may be used for increased receiving range. Antennas as long as 150 to 200 feet may be employed in "dead spots." (Longer antennas increase sensitivity and decrease selectivity slightly.)

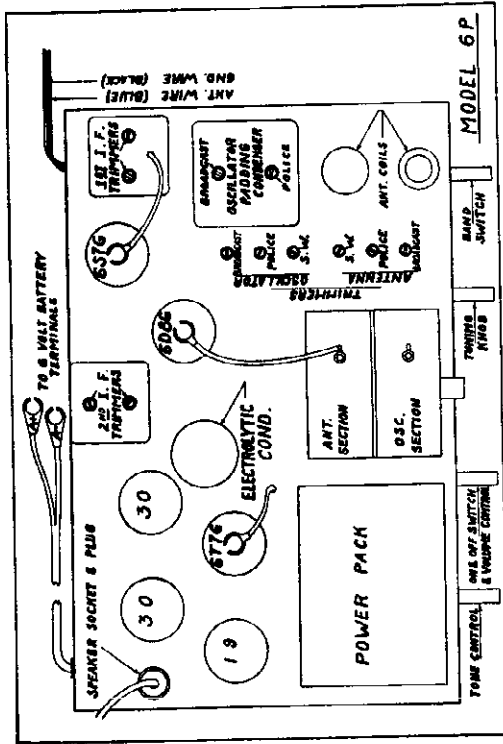

GROUND

This receiver requires a good ground. Water pipes make a very desirable ground connection. Where the wire makes contact, the pipe must be clean and free of paint or corrosion. The ground wire should be connected to the "Black" lead.

Where the above mentioned ground facilities are not available, a good outside ground may be had by staking a metal pipe or ground rod about six feet into moist earth. An excellent bed can be prepared by digging a hole and filling with charcoal, in which the ground rod is placed. The charcoal bed surrounding the ground rod will maintain a desirable moist condition throughout the year.

IMPORTANT NOTE: The battery must never be charged while set in operation. If a recharger, when it should always be disconnected from the set, is being used, an insulating switch can be used for disconnecting the battery from the set. This will increase the life of the tubes and give additional economy to the use of the receiver.

This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (176 to 545 meters), Police and Aviation Band which extends from 1700 to 5400 Kilocycles (KC) (56 to 176 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) (16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

NOTICE — MICROPHONIC NOISE CORRECTION
 If this radio instrument appears to be microphonic during operation, loosen the four (4) mounting screws that secure the chassis to the cabinet and remove the two (2) wooden strips that are underneath the chassis. This allows the chassis to float and rest on the four (4) rubber pads used for this purpose. After the strips have been removed, adjust the

INSTALLATION

BATTERY CONNECTIONS At the rear of the receiver there will be found extending from the right end of the chassis, the battery connecting cable. Observation will show that 5 wires are brought out from the braided cable. The red and red with black tracer wires are joined together and should both be securely fastened to the positive (+) terminal of the 6 volt storage battery. The other 3 wires which are brown, black with green tracer and metallic shield lead are also joined together and should be securely connected to the negative (-) post of the battery.

Note: It is extremely important that only the best possible means of obtaining a secure connection to the battery terminals be employed. If a battery with auto-

mobile terminal posts is used, the large post is the positive (+) post; the smaller post is the negative (-) terminal. It is suggested, when using a battery with auto type posts that large heavy lead covered battery clips be used in making connections. Make sure that all wires are firmly connected to clips (solder if possible). Also see that the low teeth of the clips are clean, and firmly bite into the post. It is very important that the battery posts and battery clip teeth be cleaned at frequent intervals to assure maintaining good connections. Corrosion may be readily removed by cleaning with a solution of 3 tablespoons of bicarbonate of soda (baking soda) and one cup of water. This solution neutralizes the acid coating that causes the corrosion and leaves a protective condition that retards further corrosion. It is important that this solu-

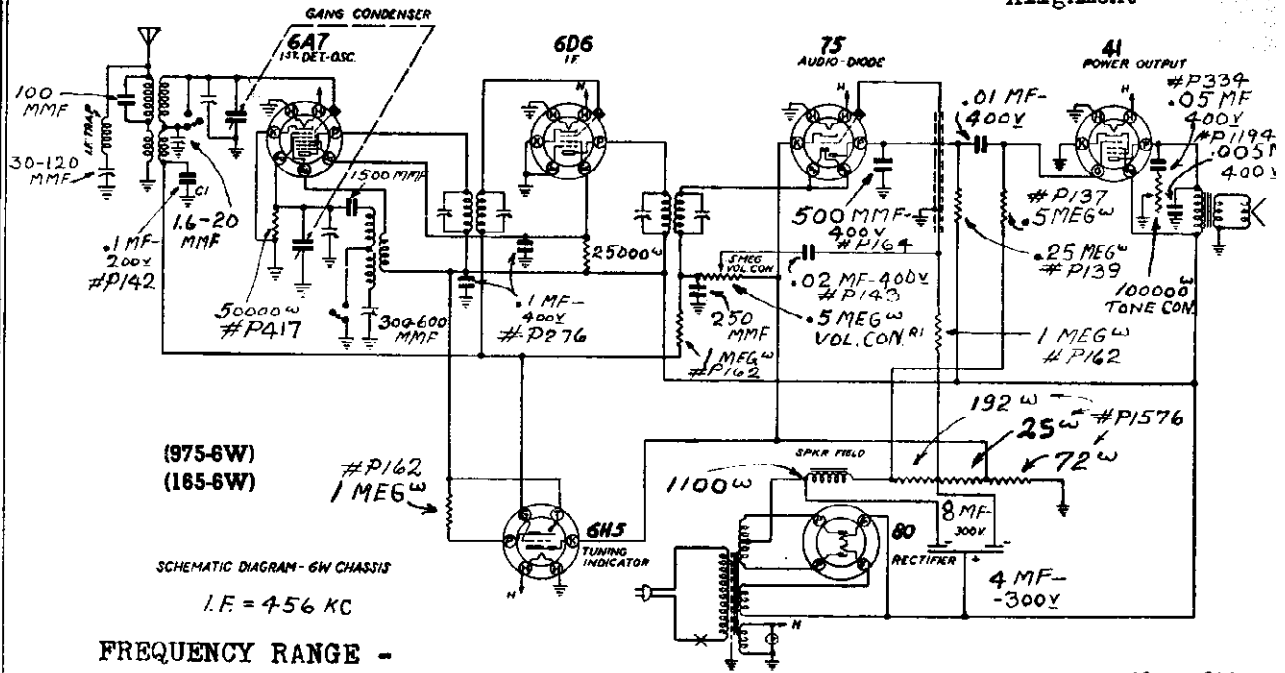

tion be used in the cabinet so that the dial will be in the center of the front escutcheon plate. Do not retighten the mounting screws.
 "Should this radio set be moved any great distance, it is best to put the wooden strips back under the chassis and have the mounting screws securely tightened. If this is not done, damage may be done to the instrument, cabinet or tubes."

MODEL 7M CHASSIS

This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (176 to 545 meters), Police and Aviation Band which extends from 1700 to 5400 Kilocycles (KC) (56 to 176 Meters) and International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) (16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this done by slowly increasing or decreasing the oscillation of the receiver requires the frequency tuning knob and, at the same time, connect the tuning knob and forth across the signal of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, 16,000 with the maximum reading is observed on the output meter to be connected with the receiver until the maximum reading is observed on the output meter. This adjustment may be made with the volume control on maximum and the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stage should be aligned properly on the first step. After the I.F. transformer has been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the Broadcast Band maximum output As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 5000 KC and the gang condenser set at minimum. Adjust the sensitivity of the receiver through a .002 mica antenna lead. Then set the gang to minimum and adjust the "oscillator trimmer" to receive this signal. Then set the generator to 1730 KC and tune in this set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set the generator to 180 KC and tune in this set the generator to 600 KC and adjust the antenna trimmer to receive maximum output. Owing to the nature of the long wave antenna trimmer, the trimmer and padding condensers react upon each other to quite a degree; consequently several re-adjustments at the trimming and padding positions are required before the circuits are adjusted to the same sensitivity should be noted at this point.

SHORT WAVE BAND ALIGNMENT

Connect the output of their rugged construction and liberal ratings. The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 5000 KC and the gang condenser set at minimum. Adjust the sensitivity of the receiver through a .002 mica antenna lead. Then set the gang to minimum and adjust the "oscillator trimmer" to receive this signal. Then set the generator to 1730 KC and tune in this set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set the generator to 180 KC and tune in this set the generator to 600 KC and adjust the antenna trimmer to receive maximum output. Owing to the nature of the long wave antenna trimmer, the trimmer and padding condensers react upon each other to quite a degree; consequently several re-adjustments at the trimming and padding positions are required before the circuits are adjusted to the same sensitivity should be noted at this point.

BROADCAST BAND ALIGNMENT

Connect the output of their rugged construction and liberal ratings. The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 5000 KC and the gang condenser set at minimum. Adjust the sensitivity of the receiver through a .002 mica antenna lead. Then set the gang to minimum and adjust the "oscillator trimmer" to receive this signal. Then set the generator to 1730 KC and tune in this set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set the generator to 180 KC and tune in this set the generator to 600 KC and adjust the antenna trimmer to receive maximum output. Owing to the nature of the long wave antenna trimmer, the trimmer and padding condensers react upon each other to quite a degree; consequently several re-adjustments at the trimming and padding positions are required before the circuits are adjusted to the same sensitivity should be noted at this point.

MODEL 7MU CHASSIS

This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (173 to 562 meters), Longwave Band which extends from 375 to 150 Kilocycles (KC) (800 to 2000 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) (16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this for padding condenser and, at the same time, connect the tuning knob and forth across the signal of 16, 25, 380, 456, 600, 1400, 1730, 6000, 16,000 with the maximum reading is observed on the output meter to be connected with the receiver until the maximum reading is observed on the output meter. This adjustment may be made with the volume control on maximum and the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stage should be aligned properly on the first step. After the I.F. transformer has been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

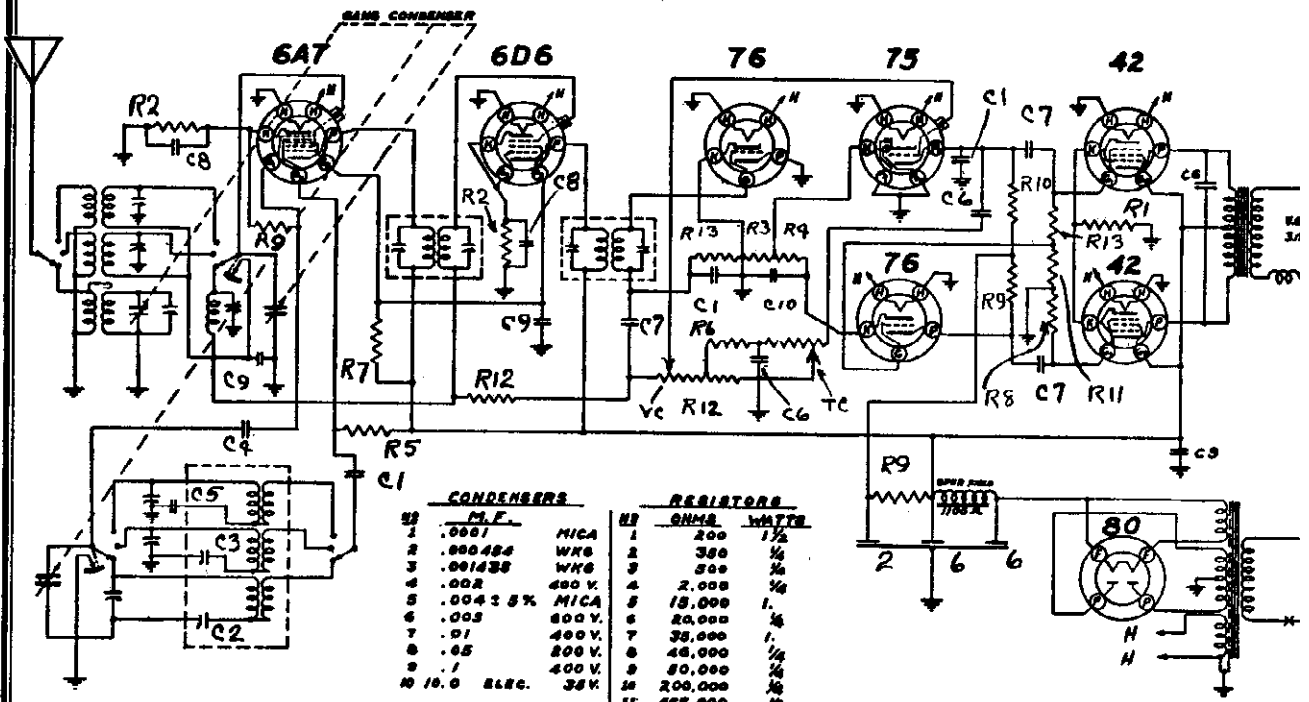

I.F. ALIGNMENT

With the wave switch in the Broadcast Band maximum output As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 5000 KC and the gang condenser set at minimum. Adjust the sensitivity of the receiver through a .002 mica antenna lead. Then set the gang to minimum and adjust the "oscillator trimmer" to receive this signal. Then set the generator to 1730 KC and tune in this set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set the generator to 180 KC and tune in this set the generator to 600 KC and adjust the antenna trimmer to receive maximum output. Owing to the nature of the long wave antenna trimmer, the trimmer and padding condensers react upon each other to quite a degree; consequently several re-adjustments at the trimming and padding positions are required before the circuits are adjusted to the same sensitivity should be noted at this point.

BROADCAST BAND ALIGNMENT

Connect the output of their rugged construction and liberal ratings. The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 5000 KC and the gang condenser set at minimum. Adjust the sensitivity of the receiver through a .002 mica antenna lead. Then set the gang to minimum and adjust the "oscillator trimmer" to receive this signal. Then set the generator to 1730 KC and tune in this set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set the generator to 180 KC and tune in this set the generator to 600 KC and adjust the antenna trimmer to receive maximum output. Owing to the nature of the long wave antenna trimmer, the trimmer and padding condensers react upon each other to quite a degree; consequently several re-adjustments at the trimming and padding positions are required before the circuits are adjusted to the same sensitivity should be noted at this point.

 8K Chassis
 ALIGNMENT DATA AND SERVICING**

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, 16,000 and 18,100 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillating condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the preselector of the R.F. section. Return to 1400 KC and again go over the adjustments of this frequency to be certain if they were not put slightly out of alignment when adjustment was made at 600 KC.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

POLICE BAND ALIGNMENT

The police band is adjusted by first replacing the .01 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit of this frequency as described in the instructions for padding the broadcast circuits.

I.F. ALIGNMENT

With the wave switch in the Broadcast Band and the gang condenser set at minimum. Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "preselector" and "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** approximately the same sensitivity should be noted at this point as was at 1400 KC. The

MODEL 8K Chassis

 Dial Adjustments

CONTINENTAL RADIO & TELEV. CORP.

**PROCEDURE FOR SETTING TELEPHONE DIAL STATIONS
 CHOOSING THE STATIONS TO BE USED**

The telephone dial has 10 buttons located in a ring within the dial scale. Make a list of 10 of your favorite stations, stations which are tuned in regularly. Shown in Fig. 1 is the approximate frequency

range that each button will cover. **Note:** If 2 stations happen to fall within the range of one button, one station will necessarily have to be tuned in with the selector knob.

**PROCEDURE FOR ADJUSTING THE
 TELEPHONE DIAL BUTTONS**

(1) Choose one of the stations out of the list of stations selected and by means of the station selector very carefully tune in this station, noting at the same time the exact pointer location on the dial.

(2) Now select the proper button for the first station chosen by referring to Fig. 1 and noting the button into whose range the station falls. For example, station WGN with a frequency of 720 KC comes under the button whose frequency ranges from 670 to 755 KC. Usually the button nearest the tuning point or the bottom of the dial will be the proper button.

(3) Loosen the button by unscrewing it (not the dial) 1/2 turn to the left. Now press the button in all the way and rock the dial back and forth a trifle until a click is heard. Do not release the button now but set the pointer to its former location and with the dial in this position, being careful not to move it, proceed to tighten the button by turning it in the opposite direction (to the right). Make sure the button is very securely tightened as it may get out of adjustment.

(4) From the station call sheet supplied remove the proper station disc and insert into the push button so that the wording is horizontal when the button is at the bottom, and then insert a clear celluloid insert. Follow this same procedure for the remaining buttons.

(5) If for any reason it is necessary to remove a station call letter disc, the use of a pen knife or any sharp pointed instrument will facilitate the removal.

**HOW TO TUNE IN STATIONS ON
 THE TELEPHONE DIAL**

Press in the button of the station desired tuned and rotate the dial slowly until a click is heard and the dial will not turn in either direction until the button is released. The station is now tuned in and can be adjusted to the volume desired by means of the volume control. The proper direction of rotation of the dial can be determined by turning the dial in the direction which will not allow the wide space adjacent to the pointer to converge into the space at the bottom of the dial. See Fig. (1).

CONTINENTAL RADIO & TELEV. CORP.

PROCEDURE FOR SETTING TELEPHONE DIAL STATIONS CHOOSING THE STATIONS TO BE USED

The telephone dial has 10 buttons located in a ring within the dial scale. Make a list of 10 of your favorite stations, stations which are tuned in regularly. Shown in Fig. 1 is the approximate frequency range that each button will cover. **Note:** If 2 stations happen to fall within the range of one button, one station will necessarily have to be tuned in with the selector knob.

(3) Loosen the button by unscrewing it (not the dial) $\frac{1}{2}$ turn to the left. Now press the button in all the way and rock the dial back and forth a trifle until a click is heard. Do not release the button now but set the pointer to its former location and with the dial in this position, being careful not to move it, proceed to tighten the button by turning it in the opposite direction (to the right). Make sure the button is very securely tightened as it may get out of adjustment.

(4) From the station call sheet supplied remove the proper station disc and insert into the push button so that the wording is horizontal when the button is at the bottom, and then insert a clear celluloid insert. Follow this same procedure for the remaining buttons.

(5) If for any reason it is necessary to remove a station call letter disc, the use of a pen knife or any sharp pointed instrument will facilitate the removal.

Figure 1

HOW TO TUNE IN STATIONS ON THE TELEPHONE DIAL

Press in the button of the station desired tuned and rotate the dial slowly until a click is heard and the dial will not turn in either direction until the button is released. The station is now tuned in and can be adjusted to the volume desired by means of the vol-

ume control. The proper direction of rotation of the dial can be determined by turning the dial in the direction which will not allow the wide space adjacent to the pointer to converge into the space at the bottom of the dial. See Fig. (1).

I.F. ALIGNMENT

With the wave switch in the Broadcast Band and the gang condenser set at minimum. Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "preselector" and "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the preselector of the R.F. section. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 K.C.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

LONG WAVE BAND ALIGNMENT

The long wave band is adjusted by connecting the output of the signal generator through a .0002 Mfd. mica condenser to the blue antenna lead. Then set the gang to minimum and the generator to 380 KC and adjust the long wave oscillator trimmer to receive this signal. Then set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set generator to 160 KC and pad the circuits to maximum output. Owing to the nature of the long wave band, the trimmer and padding condensers react upon each other to quite a degree; consequently, several re-adjustments at the trimming and padding positions are required before the circuits are adjusted properly.

ANTENNA WIRE (BLUE) GROUND WIRE (BLACK) POWER CORD & PLUG

MODEL 118**Alignment
Notes****CONTINENTAL RADIO & TELEV. CORP.****ALIGNMENT DATA AND SERVICING****GENERAL DATA**

The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, 16,000 and 18,100 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

**CORRECT ALIGNMENT
PROCEDURE**

The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure, after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the Broadcast Band and the gang condenser set at minimum push in the white button until it locks. Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align the first four I.F. trimmers to peak or maximum reading on the output meter.

After the first two I.F. transformers have been tuned, the discriminator transformer should be aligned. This is a critical adjustment and must be performed with care.

First — connect a 0-200 micro ammeter between the ungrounded cathode of the 6J5G tube serving as a diode rectifier, and ground. This cathode is indicated as point "A" in the circuit diagram. Then place a .0001 mfd. mica condenser across the secondary of the discriminator transformer. These terminals are indicated as points "D1" and "D2" on the circuit diagram. This condenser is used to detune completely the secondary circuit during the following primary adjustment.

The primary is tuned by impressing an I.F. signal on the converter (6A8-G) grid and adjusting the trimmer marked "DISC. PRI." on the chassis layout diagram, to give maximum audio output. Signal strength should be the same as in an ordinary aligning operation. For this particular receiver about 30-micro volts of I.F. signal is required for standard output. (50 milliwatts). At this point it would be well to go over the adjustments of the two other I.F. transformers and bring the entire system to maximum sensitivity. Now without further adjustments of either the frequency setting of the signal generator or the I.F. transformer trimmers the "DISC. SEC." trimmer should be tuned.

After removing the .0001 mfd. mica condenser from the 6J5G grids "D1 and D2" increase the I.F. signal input to the maximum that the signal generator will supply (at least 100,000 micro volts). Then, with the volume control turned down to limit the audio output, slowly turn the "DISC. SEC." trimmer until a sudden, sharp drop in current as indicated by the micro ammeter is seen. The meter will now probably read in reverse and off scale. The trimmer should be reversed and the meter reading brought to zero. If a metallic screw driver is used it will be necessary, continually, to

lift the screw driver away from the trimmer screw after each slight adjustment to observe the meter reading.

It is sometimes convenient to use an offset of "remote zero" setting of the micro ammeter in making this adjustment so that the zero current setting is higher on the scale than the conventional zero point.

After the current has been brought to zero by the above described method the I.F. alignment and discriminator tuning is completed and the R.F. tracking may be done.

**BROADCAST BAND
ALIGNMENT**

Connect the output of the signal generator to the antenna lead (blue) through at .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "preselector" and "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the preselector of the R.F. section. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

**POLICE BAND
ALIGNMENT**

The police band is adjusted by first replacing the .0002 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit of this frequency as described in the instructions for padding the broadcast circuits.

**SHORT WAVE BAND
ALIGNMENT**

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

CONTROLS AND OPERATION**RIGHT HAND KNOB**

(Three Position Wave Band Selecting Switch)—Turned to the right, it is set for Standard Broadcast Band; turned to the extreme left, it is set for Foreign and American Short Wave Reception; when in the center position, it is set for reception of Police, Aviation, Amateurs, and Ships at Sea.

SHORT WAVE TUNING

When tuning short wave stations, the selector knob must be turned more slowly and carefully, due to the sharp selectivity of the receiver in these bands. If you tune rapidly, many stations will be skipped entirely. When a response is heard, work the dial a little from left to right until you hit a point where the station comes in at maximum volume. This critical tuning is necessary if results are to be expected. It may require a little patient experimenting to become accustomed to short wave tuning. The use of a short wave "log" will be of great assistance in picking up short wave stations. Such logs are available from any of the leading radio magazines. They list the location, frequency and operating time schedules of short wave stations all over the world.

(Three Position Wave Band Selecting Switch)—**LEFT HAND KNOB**

Turned to the extreme right. The switch will click and the dial will become illuminated. Wait about one-half minute for the tubes to become heated.

LEFT CENTER KNOB

(Continuous Variable Tone Control)—The tone control permits tonal regulation to meet individual musical taste. When turned completely to the right the normal proportion of high to low notes is obtained. Upon turning the control from the extreme right position toward the center a gradually increasing emphasis of the low notes is noted. Further, increase in this direction serves to eliminate the more extreme "highs" which result in a greater apparent bass increase. A very useful application of this particular type of tone control is its ability to compensate for apparent lack of base at low volume levels. If when listening to a musical program at a low volume level the tone control is set at a position half way between its extreme settings a very pleasing effect is obtained.

(Manual Volume Control and "On-Off" Switch)—

Turn the left

(Continuous Variable Tone Control)—

The tone control permits tonal regulation to meet individual musical taste. When turned completely to the right the normal proportion of high to low notes is obtained. Upon turning the control from the extreme right position toward the center a gradually increasing emphasis of the low notes is noted. Further, increase in this direction serves to eliminate the more extreme "highs" which result in a greater apparent bass increase. A very useful application of this particular type of tone control is its ability to compensate for apparent lack of base at low volume levels. If when listening to a musical program at a low volume level the tone control is set at a position half way between its extreme settings a very pleasing effect is obtained.

CONTINENTAL RADIO & TELEV. CORP.

MODEL 11S
Electric Tuner
Data

11S Chassis

INSTRUCTIONS FOR ADJUSTMENT AND OPERATION OF THE ELECTRIC TUNE

It is very important to read the following instructions carefully before attempting to adjust the electric tuner. The electric tuner is made up of three integral units:

PUSH BUTTON SWITCH: The push button switch consists of one (1) white button (extreme left), and eight (8) brown buttons whose numerical sequence is reckoned from left to right. The white button is provided for converting the set from automatic electric push button tuning to manual knob tuning. The brown buttons are provided for automatic electric tuning.

SELECTOR MECHANISM: The selector mechanism is made up of the selector plate, eight (8) thumb screws, and the adjustment light bulb.

ELECTRIC MOTOR: The power for this tuner is provided by a small, efficient electric motor, of the brushless variety. It is fitted with an automatic clutch and a silent gear train. The bearings and the oil retainer hold sufficient oil to lubricate the motor for a lifetime.

Fig. 1

The first step to take in adjusting the electric push button de incorporated into this receiver is to choose eight (8) of the 1 powerful local stations, stations which are free from excess fat Turn on the receiver (broadcast band) and press in the white ton; tune in the station of the **lowest frequency**, using the stc selector knob. Now hold the white button in and press in bu number one (1), next to the white button. (See Figure 1). Both tons are now locked into place; a small pilot lamp located at rear of the chassis will light up unless the thumb screw at the accidentally happens to be correctly set. Loosen thumb screw r ber one (See Figure 2 for order of thumb screws) enough to a it to slide freely back and forth until the light goes out. I tighten the thumb screw; the adjustment for the first station is complete. Out of the station call letter sheet supplied remove proper station call block and insert into the window directly at button number one. Now release button number one by pres the white button in as far as it will go.

With the white button still in, tune in the station of the next hig frequency and holding the white button, press in button nur two. Both buttons are now locked into place. Loosen thumb sc number two (see Figure 2) and slide back and forth until a r is reached at which the pilot lamp in the rear goes out; tig the thumb screw. Insert the proper station call into the windo button number two.

Follow this same procedure for the remaining stations, alv choosing the station with the next highest frequency. After eight (8) stations have been adjusted, check each adjustmen tuning in each station. Note: In the window above the w button insert the word "OFF" found in the call letter sheet.

HOW TO TUNE IN STATIONS USING THE ELECTRIC PUSH BUTTON TUNER

In order to operate the receiver satisfactorily—using the electric push button tuner, the white button must be in released position, that is, all the way out. To tune in a station, merely press the selector button which designates the station desired. **Note:** Should the station fail to come in clearly, check the adjustment by following the adjustment procedure described in the paragraph above. If by chance all of the buttons are pressed in, they may be released by pressing any one button all the way in.

To change from electric tuning to manual selecting, simply press in the white button. When the white button is in, the set may be tuned as a conventional receiver. **Note:** If it is desired to tune Short Wave or Police while the set is being operated with push buttons, it is not necessary to change over from push button tuning to manual tuning. Simply turn the band switch and proceed to tune with the selector knob. When the band switch is returned to broadcast the station last selected by button will automatically tune in by itself.

RIGHT CENTER KNOB

narrow range of the dial at a point where the desired station is located, until the station is received with maximum volume; then re-adjust the volume control to the proper level. **Never** use the station selector to adjust volume as this practice results in dis-

Fig. 2

NOTE: The white push button must be pressed in, in order to tune the set manually.

(Station Selector)—Rotate the indicator needle slowly over a perted tone quality and deficient bass response. The Volume trol **only** is to be used for this purpose. For maximum clarit indicator needle should be adjusted to the center of the covered by the station being tuned.

MODELS 77, 770

Trimmers, Alignment

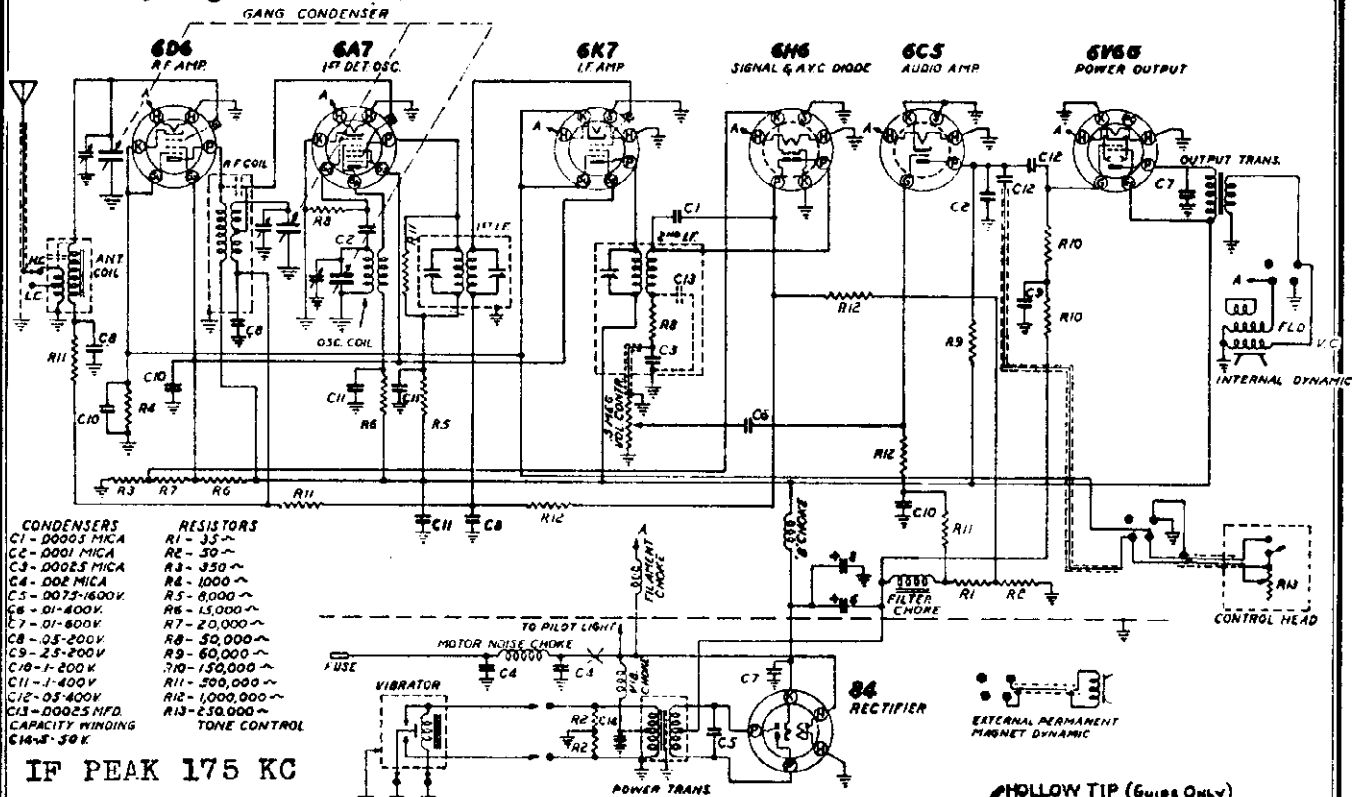

FIG. 17

7-Tube Auto Radio—
 Model 77 & 770 Chassis
 & Schematic

I.F. ALIGNMENT. Adjust the test oscillator to 175 K.C. and connect the output directly to the grid of the first detector tube (6A7), without the use of any series condenser or resistor; the omission of series condenser and resistor to block out the AVC action. The ground on the test oscillator can be connected to the chassis ground. Align the trimmers of the first and second I.F. transformers to peak or maximum reading on the output meter.

OSCILLATOR ALIGNMENT. Adjust the test oscillator to 1400 K.C. and connect the output to the antenna through

a .0001 mfd. mica condenser to give the equivalent of a low capacity type average auto antenna. Set the dial pointer to 1400 K.C. and adjust the oscillator trimmer to peak. (Front section of gang condenser.)

R.F. ALIGNMENT. The next step is to adjust the center and rear trimmers of the gang condenser to peak. The center section of the gang condenser tunes the antenna amplifier stage (6D6 tube), and the rear condenser section tunes the detector grid coil of the 6A7 tube.

Installation
Adjustments
Notes

Mount. Fasten tuner box cover in place, with the four screws. Replace the radio set cover.

MOUNTING BUTTON UNIT.

Included in the bag of parts:

- 1—Instructions
- 2—Driver screws
- 3—Steering Dash Mounting Bracket
- 4—8/32 x 3/4 R.H.M. screws
- 4—No. 8 lock washers
- 4—8/32 hex nuts
- 1—Celluloid strip
- 1—Station call letter sheet

Included with the TOUCH-O-MATIC is a printed sheet of station call letters, varying upward from 1000 wain and between 550 and 1430 K.C. These call letters are arranged in alphabetical order across the sheet. Each call letter can be selected by the use of a special call letter key. Remove the call letters to be used. Remove the celluloid strip by unscrewing the two small bolts (Fig. 2). Now place the call letters in the proper recess left exposed by the removal of the celluloid strip. Over them place the celluloid strip supplied in the bag of parts, replace the two small bolts, and fasten the station call letter sheet. The set has been mounted in the car, fasten the steering column either on the steering column or under the dash. To mount on the steering column, use the two steering post mounting straps. Bend straps to fit column. Slide bent straps through button case centered on the rear dash cover of the motor button car. Tighten the two screws. The set will hold securely to column (See Fig. 5).

For under dash mounting, a special angle bracket is supplied. This necessitates the drilling of two holes in the bottom edge of the dash. Bolts are supplied for fastening. (See Fig. 6). After the unit has been mounted in the position selected, the set is ready for operation.

OPERATION OF TOUCH-O-MATIC

Switch on the radio. Turn the volume up about half-way and wait about 30 seconds for the tubes to heat, before attempting to operate the set. Now turn the dial pointer as far as it will go to the left—to the high frequency end of the dial. Press the button corresponding to the station wanted. If the above instructions have been followed, and the adjustment has been made accurately, your station will come in precisely tuned. For manual tuning, simply press the white button and operate dial in conventional manner. For TOUCH-O-MATIC tuning, turn dial pointer to extreme high frequency end.

T-21 TOUCH-O-MATIC PARTS LIST

ADJUSTING TOUCH-O-MATIC FOR STATIONS CHOSEN.

Connect the radio to a battery and turn the set "on"; press the white button and hold down until clicking stops. (If clicking is not heard, press any red button, then press white button. If a clicking is not heard now, check all the above connections for errors.)

Turn the tuning condenser all the way out and by using a signal generator or a test oscillator, adjust the oscillator trimmer condenser located on tuning condenser to 1590 K.C. Having once made this adjustment it is important that this trimmer condenser remains untouched while making further adjustments. Now set the signal generator to 1400 K.C. and rotate the tuning condenser until the signal is received. Adjust the R.F. and Antenna trimmer condensers to the loudest signal or for the greatest deflection of an output meter. No further adjustments of trimmer condensers located by the set are necessary. Rotate the tuning condenser to the extreme high frequency end, that is, the position with the condenser plates all the way out. This is the position that the condenser plates must take when making adjustments on TOUCH-O-MATIC.

Select the five most desirable stations in your vicinity. The best selection will lie in the most powerful local stations having a frequency of less than 1430 K.C. For convenience, arrange the selected stations in order, according to their frequency—from the lowest to the highest. Press button No. 1, shown in Fig. 2. Select the station of low frequency; set the generator to this frequency. Remove the tuner box cover by removing the four screws, located in the corners of the cover, (Fig. 2). Now adjust trimmer screws "O1", "R1", and "A1" (Fig. 2) in the order named, for the loudest signal or greatest deflection of an output meter. If the frequency of the station cannot be reached with the trimmer screw completely open, cut jumper wire (See Note No. 2 below). It will be necessary to cut jumper wire for all stations having a frequency greater than 1000 K.C. When all three trimmer screws "O1", "R1" and "A1", have been adjusted for button No. 1, proceed with station No. 2.

Press button No. 2 and set the signal generator to the frequency of this station and adjust trimmers screws "O2", "R2", and "A2". Repeat this operation for the three remaining stations, using "O3", "R3", and "A3" for button No. 3; "O4", "R4", and "A4" for button No. 4; and "O5", "R5", and "A5" for button No. 5.

NOTE 2: If the frequency of the station selected cannot be reached when the trimmer screw is completely open on the cable side of the tuning unit, the four self-tapping screws (See Fig. 2) and the four nuts. Now the tuner box can be lifted off, leaving the inner mechanism exposed. Now cut jumper wire (Fig. 4) of trimmer which does not reach frequency. If any other trimmer condenser does not reach frequency when screw is completely opened, cut its trimmer wire. Now replace the tuner box, the four self-tapping screws, the four nuts, and the lug screw. Adjust trim-

mer of the installation. Depend largely upon the amount of these wires. Long leads may be used to the end of the dial.

The driver cover, No. 35 holes close to the side of the tuning condenser. Drill 3/16" holes close to the side of the tuning condenser. Locate these holes in such a manner as to provide the most direct path for the red, yellow, and blue leads. It is important that these wires be cut and filed, and that they are not in close relation to one another. Solder the wires to the tuner box to cross or come in close relation to the tuner box. The tuner box should be provided with some form of low capacity shield to capacity between any of the wires in the tuner box, as suppressor will cause excess oscillation and feed back. Solder the tuning condenser to the tuner box. Any tendency for the tuner to cause oscillation, or any tendency to capacity between these three wires. Proper shielding will stop the oscillation in all cases. If the installation will permit the choice of the yellow wire for the oscillator section, the red for the antenna section, and the blue wire for the frequency or R.F. section, the group letters "O", "A", "R", "MATIC" will have the following meaning: Oscillator, Antenna, and R.F., respectively.

If this selection of wires cannot be made, it may be necessary to add a small shield around the yellow wire in the TOUCH-O-MATIC unit. This shield should be of the low capacity variety, similar to that found on the blue wire, and not of the high capacity variety. Under every condition, the tuning condenser should be shielded. A fourth hole is necessary to allow the admittance of the shielded wire and the gray and black wire into the receiver container. The location of this hole is purely arbitrary as long as it is in the confines of the tuner box.

Fasten the tuner to the sides of the receiver by means of the four self-tapping screws provided in the bag of parts. After cutting to the proper size, solder the yellow, blue and red wires to the station-section lugs of the tuning condenser. The tuner box should be fastened to the receiver by means of the four screws provided in the bag of parts. The tuner box should be fastened to the receiver by means of the four screws provided in the bag of parts. The tuner box should be fastened to the receiver by means of the four screws provided in the bag of parts. The tuner box should be fastened to the receiver by means of the four screws provided in the bag of parts.

1. Determine whether or not the receiver in question has push-pull output.
2. Determine whether the output transformer is connected to the set or on the speaker; (if an external speaker, the speaker wires are easily accessible).
3. Determine whether the output transformer is connected to the set or on the speaker; (if an external speaker, the speaker wires are easily accessible).
After the above data is obtained, connect the gray and black wires according to the most suitable method suggested by one of the three diagrams, (Fig. 9, type 1-2-3). For sets with external or internal speaker with output transformer in chassis, use circuit Type 1. For sets with push-pull output, use circuit Type 2. For sets with push-pull output in set or on speaker, use circuit suggested in Type 3. For all other sets, use circuit suggested in Type 2.
Connect the receiver to battery and turn the set "on". Press white button and hold down until clicking stops. If no clicking is heard, check wiring carefully. Be sure that the shielded wire is connected to some source of "A" supply). Press white button again and hold down until the clicking stops. This places tuner in minimum capacity position in which no trimmer condensers are connected to the receiver. Align the set in the conventional manner. Adjust TOUCH-O-MATIC adjustment screws according to information given under the heading: ADJUSTING TOUCH-O-MATIC FOR STATIONS CHOSEN.

GENERAL INFORMATION.

The ADMIRAL TOUCH-O-MATIC Tuner can be installed on any radio receiver which uses a six volt source of supply, where the mechanical layout of the set is of such nature that the tuner unit of the TOUCH-O-MATIC may be mounted near the tuning condenser. TOUCH-O-MATIC is not a booster unit and will not increase the volume or range of the set since it contains no tubes.

INSTALLATION OF ADMIRAL TOUCH-O-MATIC ON MODELS 66, 660; 77, 770; 78, 780; 88, 880.

Remove the cover of the radio and take the set out of the container. Now press out the four knock-out slugs located on the condenser side of the container (See Fig. 1) (For models 88-880 see Note 1 before replacing set in container). Replace and secure the set in the container. Scrape away the paint from around each one of the four mounting holes, shown in Fig. 1, to insure good electrical contact with the tuner box. Fig. 2 shows a complete assembly view.

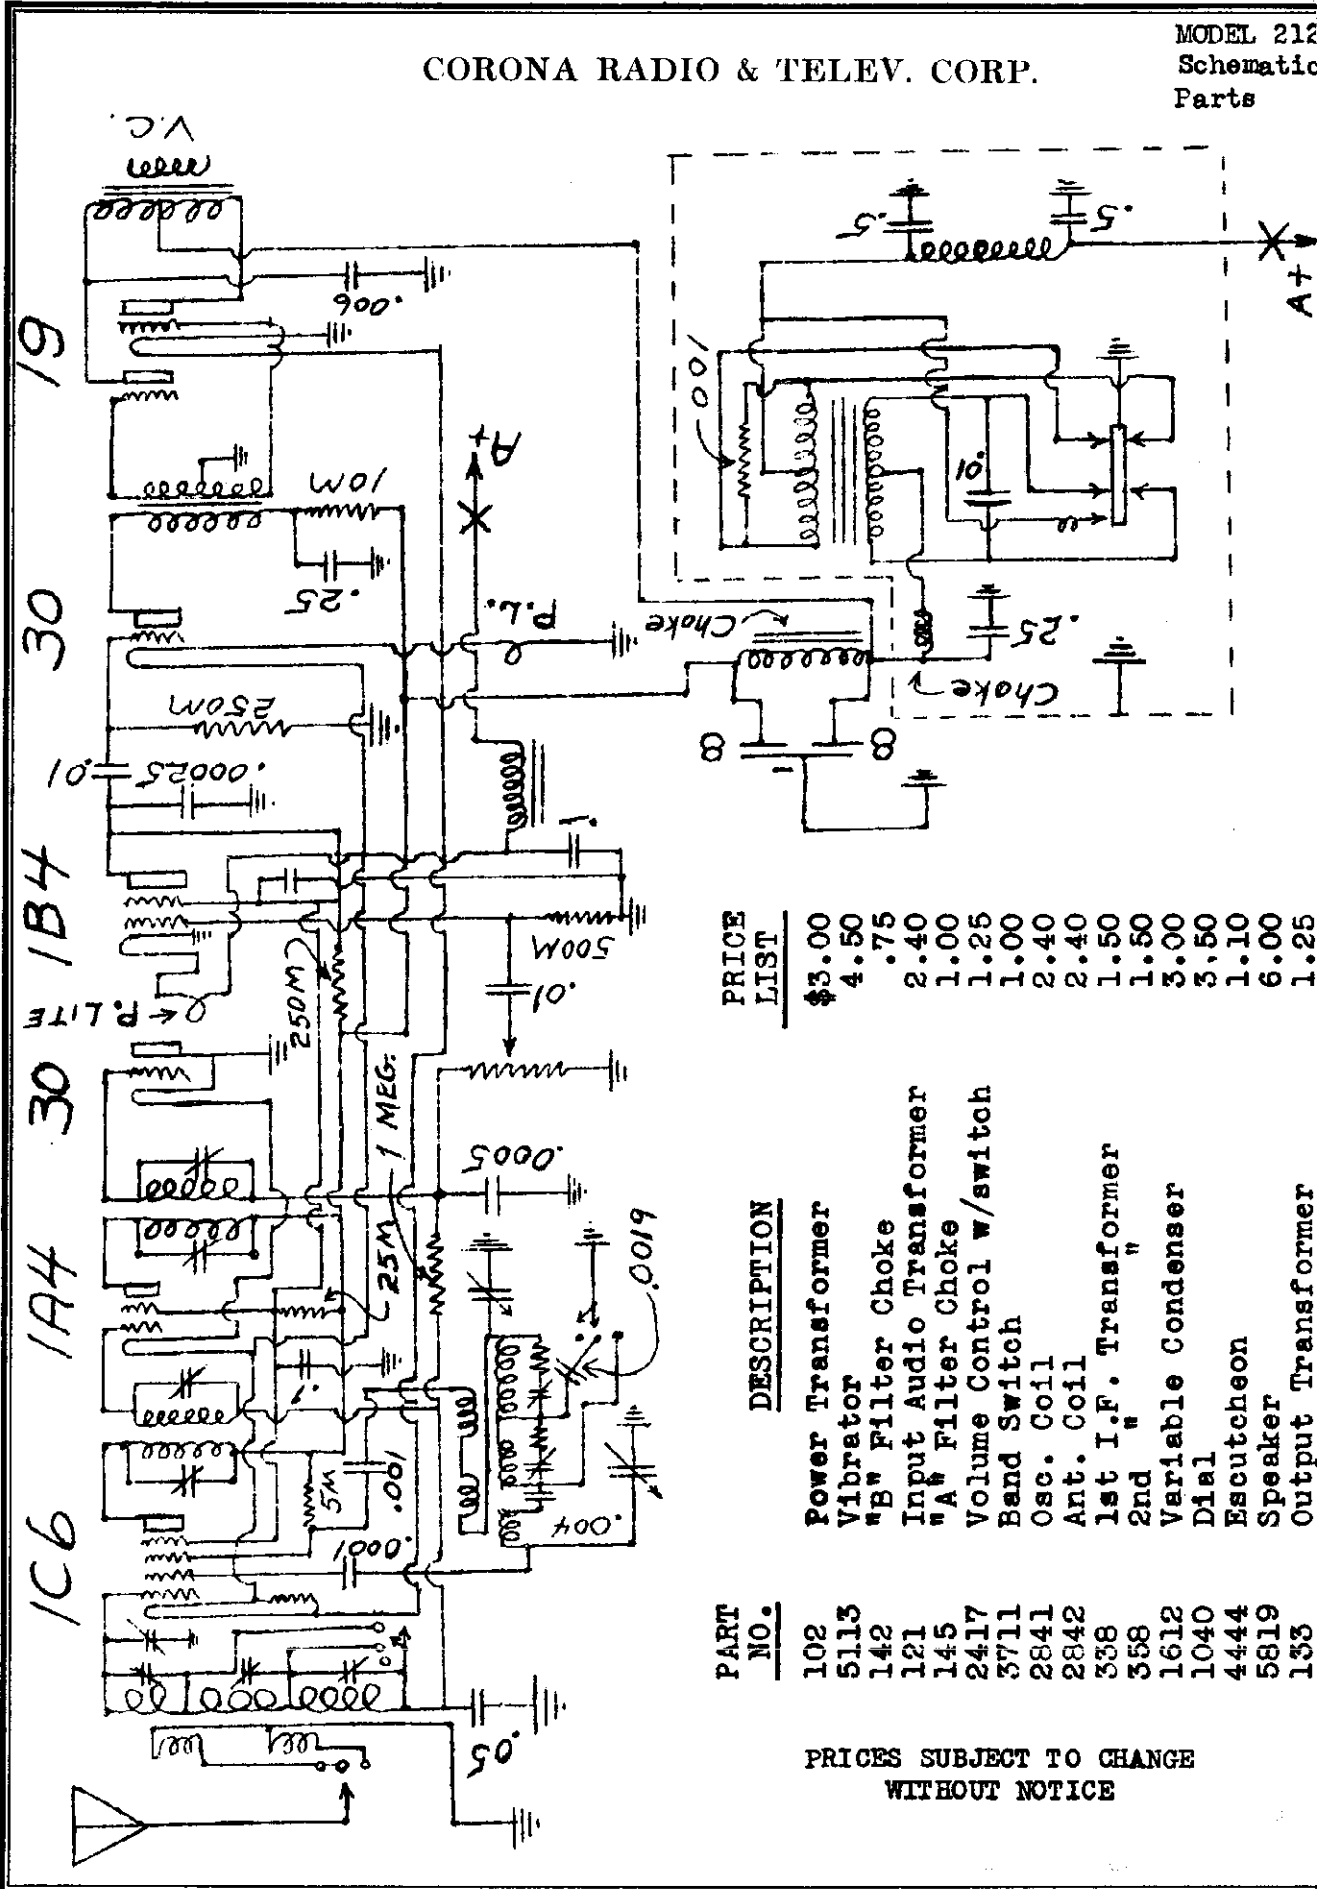

The tuner box and the button unit are shipped from the factory, connected together by a heavy cable. The only connections to be made are projecting from the open end of the tuner box. These holes are to be introduced into the four large holes in the side of the receiver container, shown in Fig. 1. Pull the gray, black, and shielded wire through hole No. 1. Through hole No. 2, pull the blue wire. Pull the red wire and the copper strap through hole No. 3, and the yellow wire through hole No. 4. Now mount the tuner box in the position shown in Fig. 2. Use the four self-tapping screws supplied in bag of parts. After the tuner box has been securely fastened to the container, remove the single section shield located at the top of the R.F. section of the tuning condenser. This may be removed by loosening the two bolts at the rear plate of the tuning condenser. Now solder the blue wire to the lug left exposed by the removal of the shield, replace the shield and tighten bolts. Make the red, blue and yellow wires as short as possible without losing the floating properties of the tuning condenser. Solder the red wire to the stator lug of the middle sector of the tuning condenser. Solder the copper strap to the frame of the tuning condenser; preferably one of the center partitions. Solder the yellow wire to the stator lug of the oscillator—front section of the tuning condenser. When the unit is being mounted on the models 66, 660; 77, 770; 78, 780; (For 88, 880 see Note 1 below) solder the gray wire to lug No. 2 of the speaker plug receptacle located in the set (See Fig. 3) Solder the wire of the shielded cable to lug No. 3 (Fig. 3). Solder the black wire to lug No. 1 (Fig. 3).

NOTE 1—When the unit is being mounted on the models 88, 880, solder the black wire to lug No. 4 (Fig. 3). Solder the shielded wire to the ungrounded side of the filament of any conveniently located tube, and the gray wire to lug No. 1 (Fig. 3). All the necessary connections are now made.

GENERAL INSTALLATION OF TOUCH-O-MATIC ON OTHER THAN ADMIRAL SETS
For receivers other than types listed above, proceed in the following order: (1) Follow the instructions carefully. (2) Determine the location of the tuning condenser unit of the TOUCH-O-MATIC. Selecting a position for the unit so that the three Radio Frequency wires can be made as short as possible. These wires are the red, yellow and blue wires which connect directly to the switch mechanism of the TOUCH-O-MATIC (See Fig. 4). The inc-

CONNECTING OUTPUT METER

Connect the output meter to P and S of the 6K6G Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 455 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A8G Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely disengaged and turn Vol. Cont. to maximum position (RIGHT).

- (c) Set the signal generator to 455 kilocycles.
- (d) Adjust both trimmers located on the 2nd I-F transformer for maximum output. Fig. 2.
- (e) Adjust both trimmers located on the 1st I-F transformer for maximum output.
- (f) Repeat operations (d) and (e) for more accurate adjustments.

IN ORDER TO PREVENT A. V. C. ACTION ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

- (b) Set the signal generator to 1400 kilocycles.
- (c) Adjust the station selector to 140 on the dial.
- (d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.
- (e) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.
- (f) Readjust the station selector for maximum output. **DO NOT READJUST THE OSC. TRIMMER.**
- (g) Repeat operation (e) for more accurate adjustment.

3. Adjusting Antenna Compensating Condenser.

- (a) Set the signal generator to 600 kilocycles.
- (b) Tune in the 600 kilocycle signal with the station selector for maximum output.
- (c) Adjust the antenna compensating condenser, Illustration No. 9, Fig. 3, for maximum output.
- (d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.
- (e) Set the signal generator to 1400 kilocycles again.
- (f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.
- (g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

- (a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.
- (b) Adjust the antenna compensating condenser for maximum volume in the speaker.

(h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

- (a) Set the signal generator to 600 kilocycles.
- (b) Tune in the 600 kilocycle signal with the station selector for maximum output.
- (c) Adjust the antenna compensating condenser, Illustration No. 11, Fig. 3, for maximum output.
- (d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.
- (e) Set the signal generator to 1400 kilocycles again.
- (f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.
- (g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

CONNECTING OUTPUT METER
Connect the output meter to P1 and P2 of the 6N6G Output tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.
NOTE:The receiver chassis should be in i.s. case and a speaker similar to one used with the receiver must be connected to the chassis before making adjustments. It is advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier To 262 Kilocycles.

- (a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A8G Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**
- (b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.
- (c) Set the signal generator to 262 kilocycles.
- (d) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2).
- (e) Adjust both trimmers located on the 1st I-F transformer for maximum output.
- (f) Repeat operations (d) and (e) for more accurate adjustments.

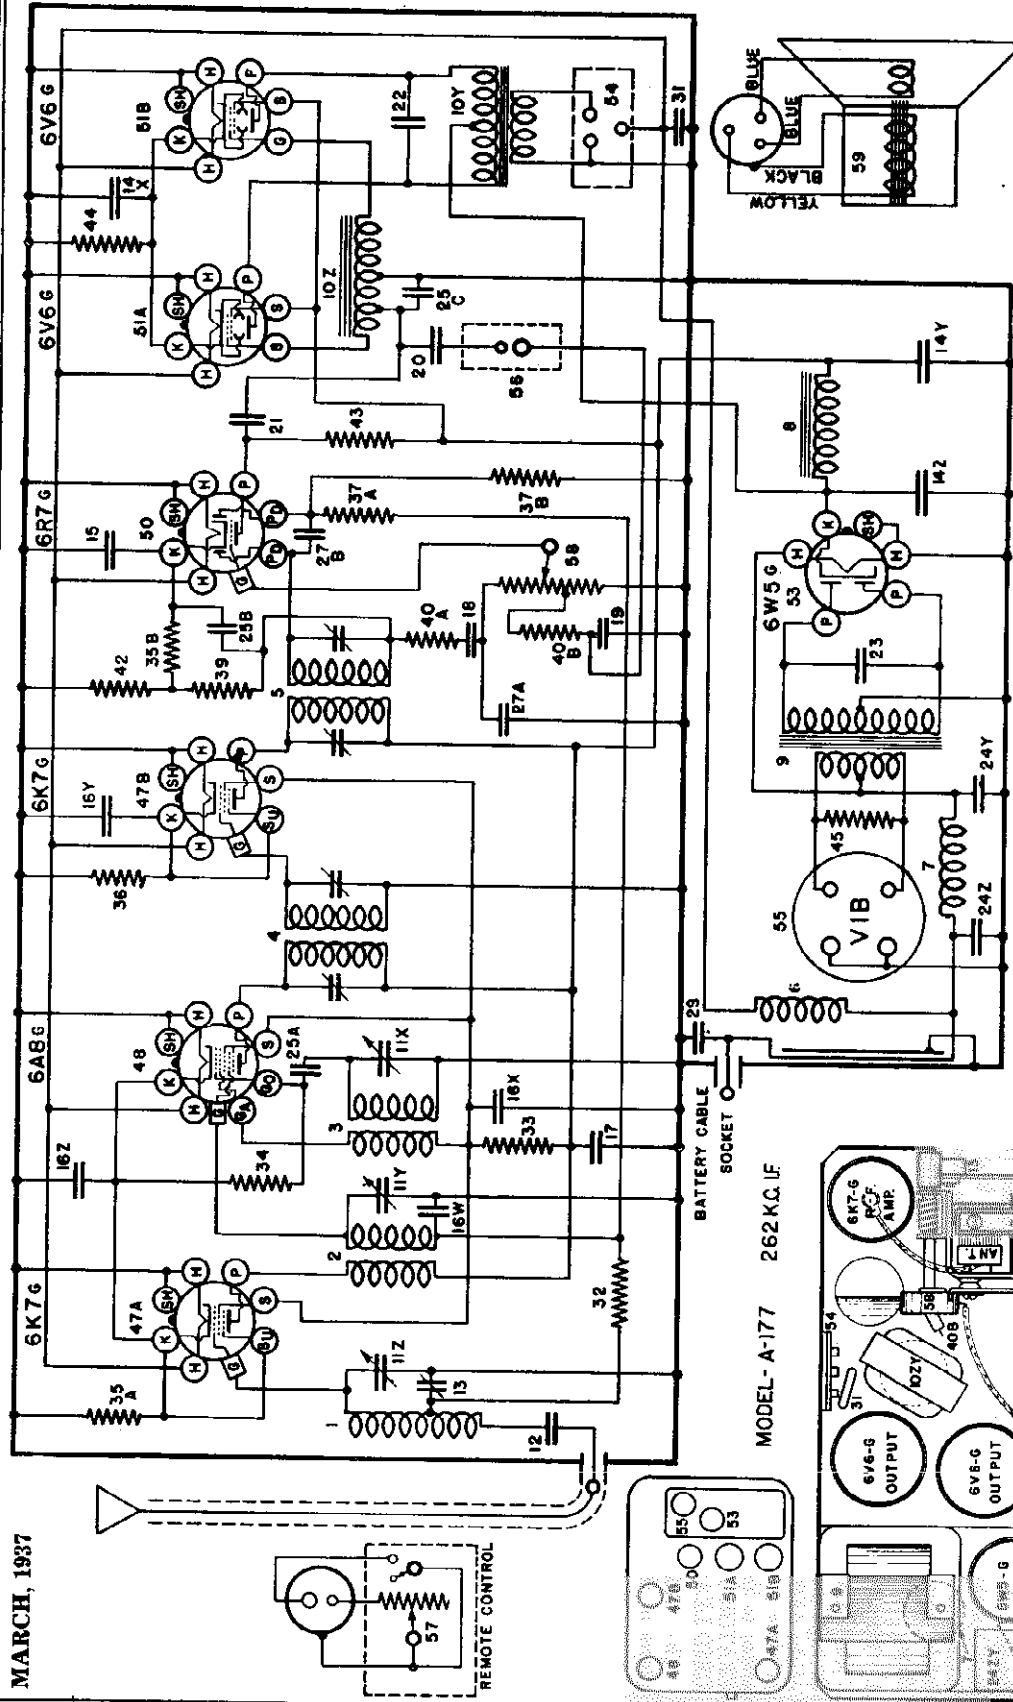

2. Aligning R-F Amplifier

- (a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" section of the receiver.
- (b) Set the signal generator to 1400 kilocycles.
- (c) Adjust the station selector to 140 on the dial.
- (d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.
- (e) Adjust the trimmer on the "R.F." section of the tuning condenser for maximum output.
- (f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.
- (g) Readjust the station selector for maximum output. **DO NOT READJUST THE OSC. TRIMMER.**

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.
 (g) Readjust the station selector for maximum output. **DO NOT READJUST THE OSC. TRIMMER.**
 (h) Repeat operations (e) and (f) for more accurate adjustments.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycles.
 (b) Tune in the 600 kilocycle signal with the station selector for maximum output.
 (c) Adjust the antenna compensating condenser, Illustration No. 13, Fig. 3, for maximum output.
 (d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.
 (e) Set the signal generator to 1400 kilocycles again.
 (f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.
 It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.
 (b) Adjust the antenna compensating condenser for maximum volume in the speaker.

Connect the output meter to the plate (P) terminals of the 6V6G output tubes. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

NOTE: The receiver chassis should be in its case and a speaker similar to one used with the receiver should be connected to the chassis before making any adjustments. It is also advisable to use a spare control unit for making adjustments of the volume control and tuning condenser. A standard control unit with short cables (6" to 8") makes a very convenient and useful tool. If it is desired to shorten a pair of long cables it will be absolutely necessary to heavily tin the cables before cutting them.

1. Tuning I-F Amplifier To 262 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A8G Osc.-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**
 (b) Adjust the station selector so that the rotor plates of the tuning condenser are completely in mesh.
 (c) Turn the volume control full on.
 (d) Leave the Fidelity Control cable disconnected from the chassis as this automatically sets the Fidelity Control in the TREBLE position and the Bass Compensation control in the OFF position.
 (e) Set the signal generator to 262 kilocycles.
 (f) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2).
 (g) Adjust both trimmers located on the 1st I-F transformer for maximum output.
 (h) Repeat operations (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" section of the receiver.
 (b) Set the signal generator to 1400 kilocycles.
 (c) Adjust the station selector to 140 on the dial.
 (d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.
 (e) Adjust the trimmer on the "R-F" section of the tuning condenser for maximum output.

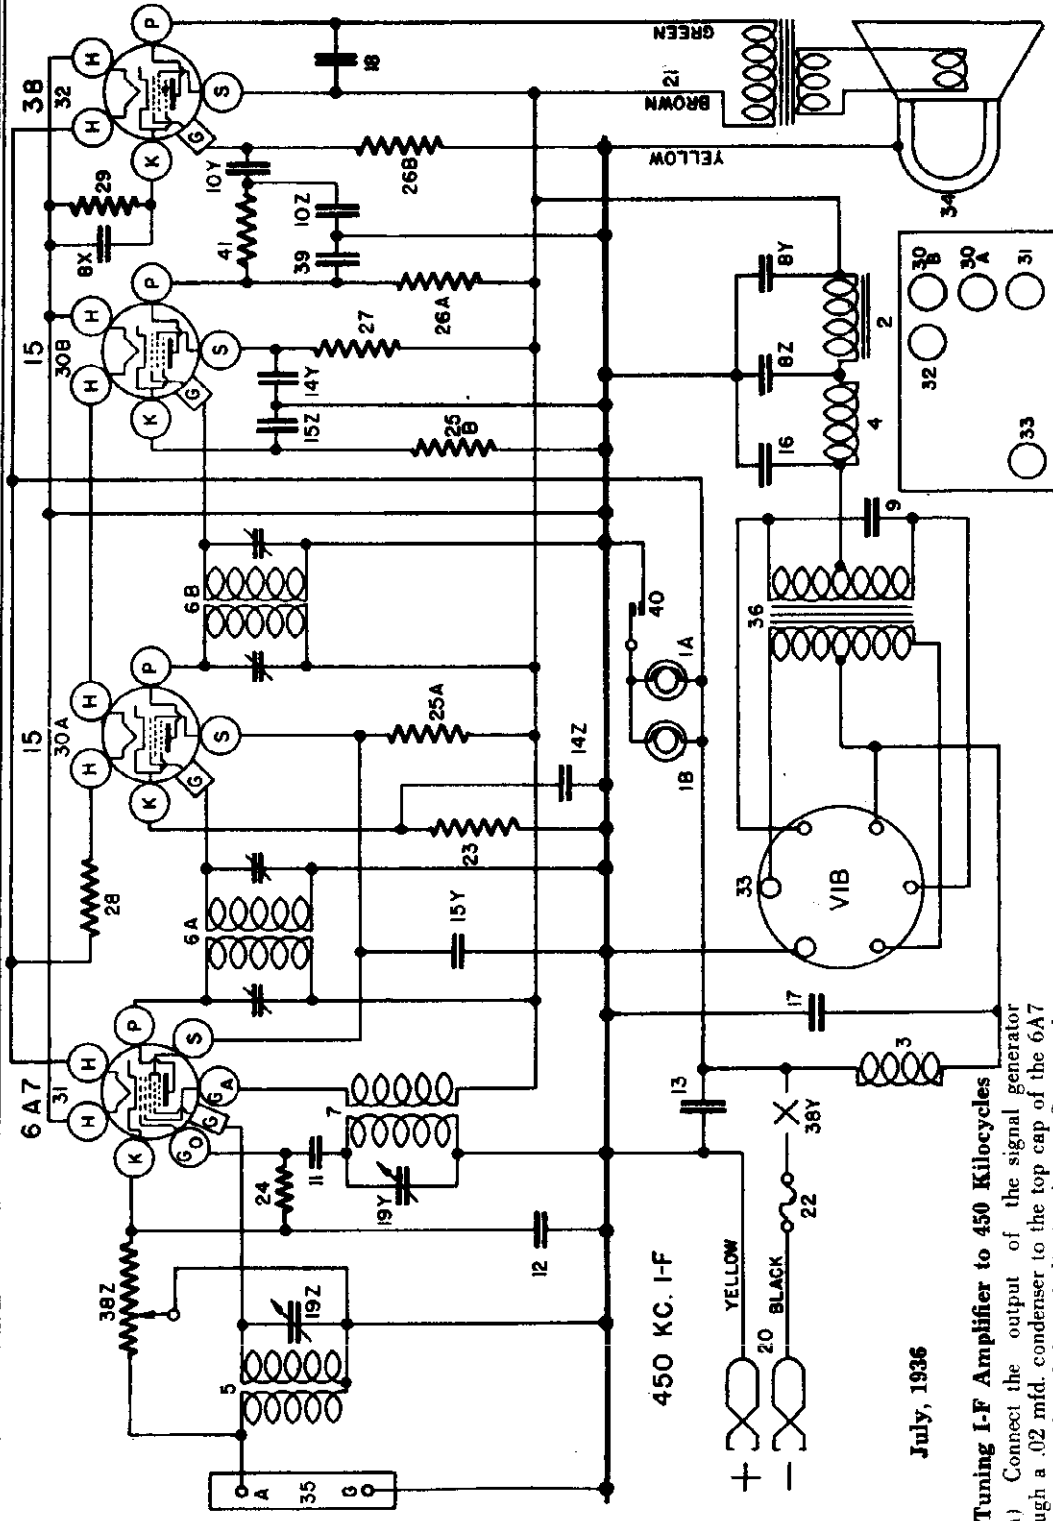

Item No.	Part No.	Description

MODEL 416
Schematic, Voltage
Socket, Alignment

Tube	Where Used	S	G	S	G	K	Ga	Go
6A7	Osc.-Mod.	6.3	185	70	0	2.5	185	-10 to -20
15	I-F Amplifier	2.1	185	70	0	2.5	—	—
15	Detector	2.1	20	4	0	4.5	—	—
38	Output	6.3	170	185	0	11.0	—	—

POWER OUTPUT APPROXIMATELY 1 WATT.
"A" BATTERY DRAIN APPROXIMATELY 1.95 AMPERES AT 6 VOLTS.

- Tuning I-F Amplifier to 450 Kilocycles**
 - Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**
 - Adjust the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).
 - Set the signal generator to 450 kilocycles.
- Aligning R-F Amplifier.**
 - Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.
 - Set the signal generator to 1400 kilocycles.
 - Adjust the station selector to 140 on the dial.
 - Adjust the trimmer on the "OSC" section of the condenser gang for maximum output. (Fig. 3.)
 - Adjust the trimmer on the "ANT" section of the condenser gang for maximum output.

Fig. 2 Top View 506

Fig. 3 Bottom View

ALIGNMENT PROCEDURE

The chassis of this receiver is connected through a resistor to one side of the power supply and for this reason all test equipment should be thoroughly isolated in order that the power supply will not be short circuited while attempting to align the receiver.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 93 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

- (a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6A7 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator direct to the receiver chassis but do not run a wire direct to ground. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.
- (b) Set the station selector so that the plates of the

condenser gang are completely out of mesh and turn the volume control to the right (ON).

- (c) Set the signal generator to 450 kilocycles.
- (d) Adjust the I-F trimmer condensers for maximum reading on the output meter.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

- (a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna lead on the chassis.
- (b) Set the signal generator to 1400 kilocycles.
- (c) Adjust the station selector to 140 on the dial.
- (d) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output.
- (e) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.
- (f) Readjust the station selector slightly for maximum output.
- (g) Repeat operation (e) for more accurate adjustment.

ALIGNMENT PROCEDURE

The chassis of this receiver is connected through a resistor to one side of the power supply and for this reason all test equipment should be thoroughly isolated in order that the power supply will not be short circuited while attempting to align the receiver.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 43 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6A7 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator direct to the receiver chassis but do not run a wire direct to ground. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the plates of the

condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the I-F trimmer condensers for maximum reading on the output meter.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead of the signal generator through a .00005 mf. condenser to the junction of the antenna and antenna blocking condenser (Items 34 and 29).

(b) Set the signal generator to 1725 kilocycles.

(c) Open gang all the way (minimum capacity).

(d) Adjust the trimmer located on the "Osc" section of the gang for maximum output.

(e) Set signal generator to 1400 Kc.

(f) Tune station selector to 1400 kc. signal.

(g) Adjust the trimmer located on the "Ant" section of the gang for maximum output.

(h) Repeat e, f, and g for more accurate adjustment.

5Y3	Rectifier	5.0	160	160	2.25	-	160

Power output approximately 2 watts.
Power consumption approximately 40 watts at 117.5 volts.
Voltage drop across speaker field 36 volts.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to P and S of the 6K6G Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 455 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8C tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the tuning condenser plates are completely out of mesh and turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 455 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments. **USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.**

2. Aligning B-F Amplifier

When aligning the B-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

(a) Set the band selector switch to the Broadcast Band.

(b) Set the signal generator to 1725 kilocycles.

(c) Open the condenser gang all the way.

(d) Adjust the "OSC" trimmer condenser for the B-C Band (38X) for maximum output.

(e) Set the signal generator to 1400 kilocycles.

(f) Tune the receiver to the generator signal for maximum output (approx. 140 on the dial).

(g) Adjust the "ANT" trimmer condenser for the B-C Band (36Z) for maximum output. **DO NOT RE-**

ADJUST THE "OSC" TRIMMER AT 1400 KILOCYCLES.

(h) Repeat operations (f) and (g) alternately until no further improvement in output can be obtained.

(i) Set the band selector switch to the H-F Band.

(j) Set the signal generator to 15,400 kilocycles.

(k) Open the condenser gang all the way.

(l) Adjust the "OSC" trimmer condenser for the H-F Band (38W) for maximum output.

(m) Set the signal generator to 15,000 kilocycles.

(n) Tune the receiver to the generator signal for maximum output (approx. 15 on the dial).

(o) Adjust the "ANT" trimmer condenser for the H-F Band (38Y) for maximum output. **DO NOT RE-ADJUST THE "OSC" TRIMMER AT 15,000 KILOCYCLES.**

(p) Repeat operations (n) and (o) alternately until no further improvement in output can be obtained.

NOTE: If at any time the H-F coils in this receiver are replaced, it may be necessary to vary the inductance of the "OSC" coil by moving the cross-over turn of wire at the gap to make the set track at the 6 megacycle end.

Moving the turn toward the short end of the coil will decrease the inductance and moving it toward the long end will increase the inductance. If the signal is weak at 6 megacycles, a similar slight change in the inductance of the "ANT" coil should bring up the signal strength. **THIS IS A CRITICAL OPERATION AND SHOULD NOT BE DONE ON ANY SET UNLESS CHANGING COILS MAKES IT NECESSARY.**

NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 910 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 910 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

REFRIGERATOR RADIO,
CHASSIS NO. 537

MARCH, 1937

MODEL 537

Trimmers, Chassis
Alignment

CROSLLEY RADIO CORP.

This model Crosley radio chassis is especially designed for installation in Crosley Shelvador electric refrigerators. It should be operated only from an ALTERNATING CURRENT power supply as specified

on the Model Label which is fastened to the inside of the refrigerator top.

The tuning range of the receiver is from 540 to 1725 kilocycles or 555 to 173 metres.

Fig. 2 Top View 537

Fig. 3 Bottom View 537

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary, the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter across the "P" and "S" terminals of the 6K6G output tube. Be certain that the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 455 Kilocycles.

(a) Connect the output of the signal generator through .02 mfd. condenser to the top cap of the 6A8G tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the tuning condenser plates are completely in mesh and turn the volume control knob to the right (ON).

(c) Set the signal generator to 455 kilocycles.

(d) Adjust both trimmers located on top of the

2nd I-F transformer for maximum reading on the output meter. (Fig. 2).

(e) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier

When aligning the R-F amplifier the output lead from the signal generator should be connected through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(a) Set the signal generator to 1725 kilocycles.

(b) Open the condenser gang all the way.

(c) Adjust the "OSC" trimmer condenser (33Y) for maximum output.

(d) Set the signal generator to 1400 kilocycles.

(e) Tune the receiver to the generator signal for maximum output (appx. 140 on the dial).

(f) Adjust the "ANT" trimmer condenser (33Z) for maximum output. **DO NOT READJUST THE "OSC" TRIMMER AT 1400 KILOCYCLES.**

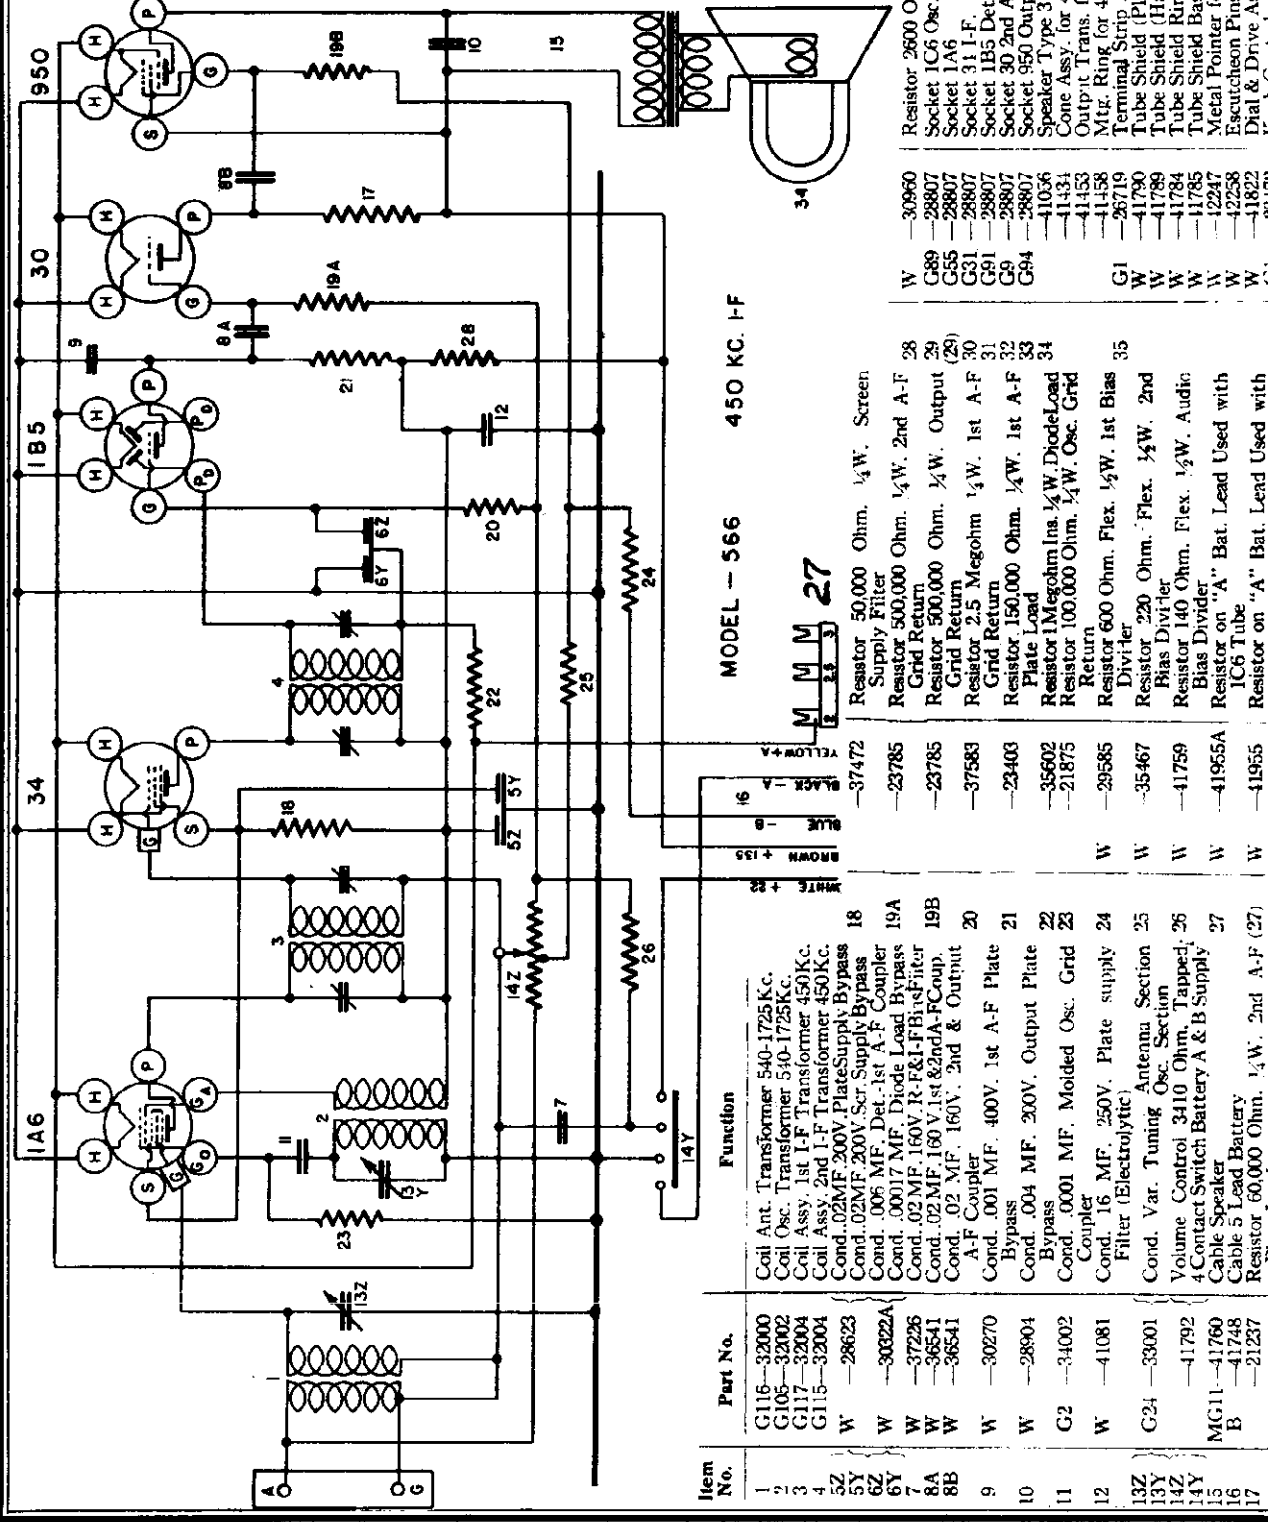

(g) Repeat operations (e) and (f) alternately until no further improvement in output can be obtained.

CROSLLEY RADIO CORP.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 950 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02, or larger, mfd. condenser to the top cap of the 1C6 Osc-Mod tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the left (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. Fig. 2.

(f) Adjust both trimmers located on top of the 1st I-F transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(i) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" terminal of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output. Fig. 3.

(e) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(f) Tune the station selector to the generator signal for maximum output.

(g) Repeat operation (e) for more accurate adjustment.

SPECIFICATIONS

This model Crosley radio is a six-tube battery receiver designed for portable use. A detachable antenna approximately 18' long is supplied as standard equipment. Provision is made for operating the receiver

either with headphones or a permanent-magnet dynamic speaker.

The tuning range is approximately from 540 to 1710 kilocycles.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 950 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 282 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 1A6 Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**
(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely out of mesh.

(c) Turn the volume control of the receiver full on.
(d) Set the signal generator to 262 kilocycles.

(e) Adjust both trimmers located on the 2nd I-F transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on the 1st I-F transformer for maximum output.

(g) Repeat operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" section of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.

(e) Adjust the trimmer on the "R.F." section of the tuning condenser for maximum output.

(f) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(g) Readjust the station selector for maximum output. **DO NOT READJUST THE OSC. TRIMMER.**

(h) Repeat operations (e) and (f) for more accurate adjustments.

(i) Set the signal generator to 600 kilocycles.

(j) Tune in this signal with the station selector for maximum reading on the output meter.

(k) Adjust the series trimmer, item 14, Fig. 2, while rocking the tuning condenser back and forth slightly until no further improvement in output can be obtained.

(l) Return the signal generator to 1400 kilocycles and repeat operations (g) and (h).

OCT. 1936

This model Crosley radio is a five-tube receiver designed for operation on a 110 to 120 volt power supply, either A. C. or D. C.
The tuning range of the receiver is approximately from 540 to 1710 kilocycles (555 to 175 meters).

25Z6G	Rectifier	25.0	---	---	---	---	---	---

TUBE SOCKET VOLTAGE READINGS

Power output approximately 1.8 watts.
Power consumption approximately 50 watts.
Voltage drop across speaker field 125 volts.
All readings taken on 117.5 volt A. C. power supply.
All readings except filaments will be approximately 10% lower on 117.5 volts D. C.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 25A6 Output tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6A8 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator through a .05 mfd., or larger, condenser to the receiver chassis. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the 2nd I-F trimmer condensers (18B, Fig. 3) located on the rear of the receiver chassis for maximum reading on the output meter.

(e) Adjust the 1st I-F trimmer condensers (18A, Fig. 3) located on the rear of the receiver chassis for maximum reading on the output meter.

(f) Check operations (d) and (e) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna condenser at the point where the antenna wire is connected.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output.

(e) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(f) Readjust the station selector slightly for maximum output.

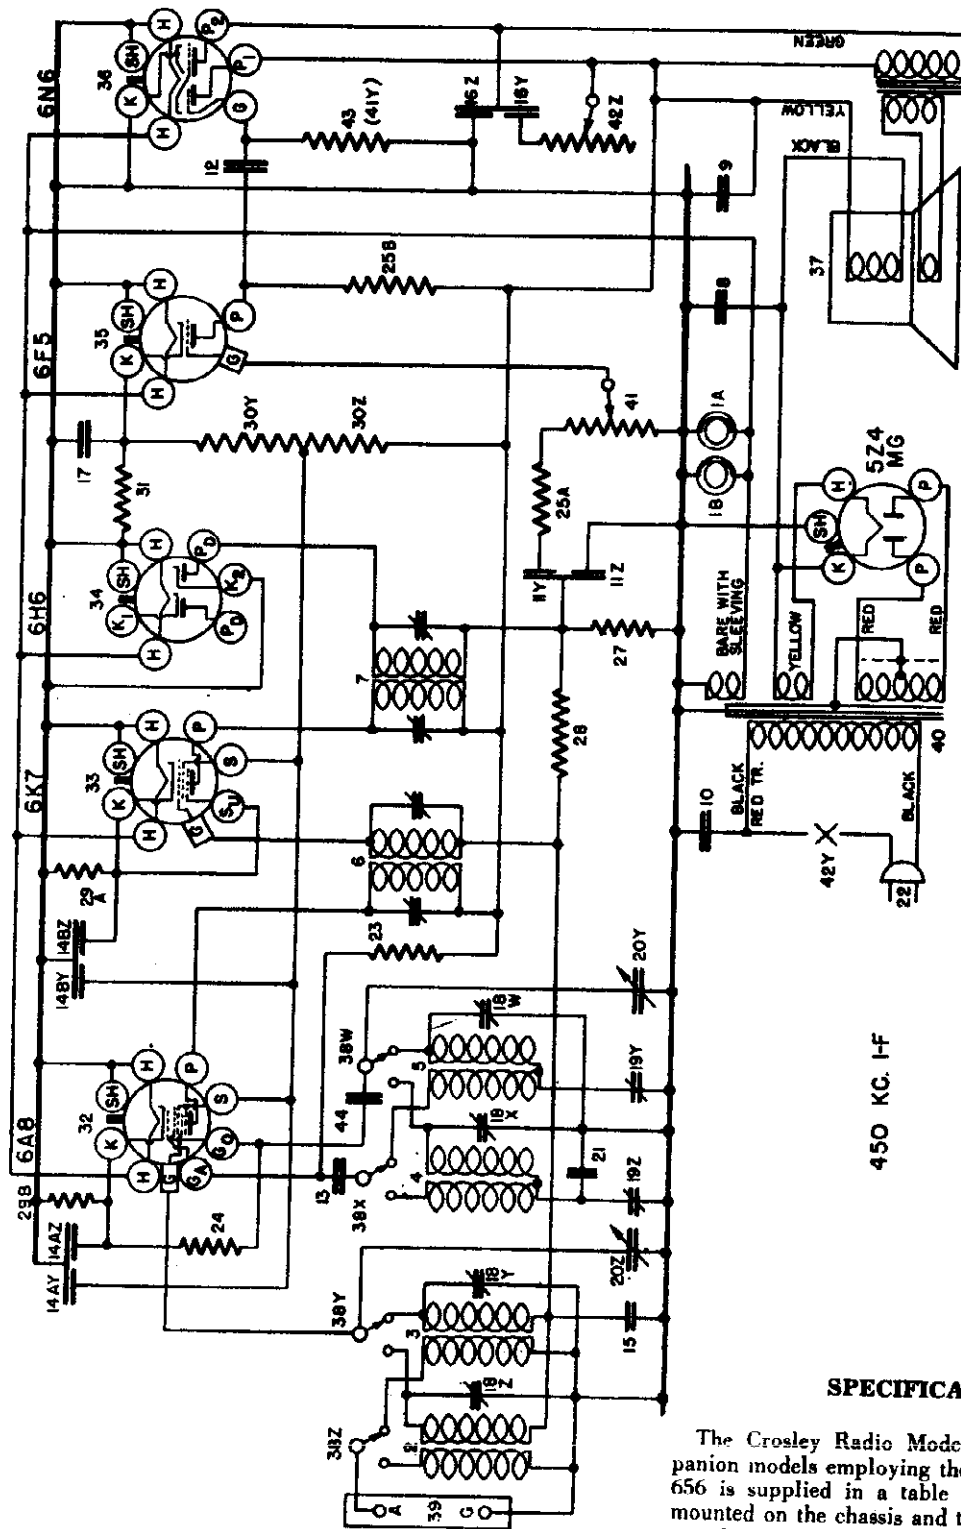

(g) Repeat operation (e) for more accurate adjustment.

CROSLEY RADIO CORP.

frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" shunt trimmers (Shunt alignment). See Fig. 3 in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. NOTE: When adjusting the high frequency band, care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 500 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 3) set the signal generator to the frequency indicated below and then tune in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to P. and P2 of the 6B5 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" shunt trimmers (Shunt alignment. See Fig. 3) in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. **NOTE:** When

aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 3) set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

Socket, Trimmers
Alignment, Parts

CROSLLEY RADIO CORP.

be set to the frequency indicated below for each adjustment.
Adjust the "OSC" and "ANT" shunt trimmers. (See Fig. 3) in the order given for maximum output. (See the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.
To adjust the "series" trimmer (Fig. 3) set the signal generator to the frequency indicated below and then tune in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.
(b) Set the station selector so that the plates of the condenser gang are completely out of mesh, turn the band selector switch to the right (High Frequency Position) and turn the volume control to the right (ON).
(c) Set the signal generator to 450 kilocycles.
(d) Adjust both trimmer condensers located on top of the 2nd I-F transformer for maximum reading on the output meter.
(e) Adjust both trimmers located on top of the 1st I-F transformer for maximum reading on the output meter.
(f) Check operations (d) and (e) for more accurate adjustments.
ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning B-F Amplifier.
(a) When aligning the B-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mid. condenser and for the high frequency band the condenser should be replaced by a 40 μ ohm (Non Inductive) carbon resistor.
Each band should be shunt aligned, series aligned (Broadcast Band) and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should

Fig. 2. Top View 676

Fig. 3. Bottom View 676

adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 2B6G Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mid. or larger—not electrolytic) in series with one of the leads.

Tuning I-F Amplifiers to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top of the 8A8 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator through a .05 mid. or larger condenser to the receiver chassis. KEEP THE GENERATOR LEADS AS

A switch is located on the rear of the receiver chassis for the purpose of adapting the receiver to either an A.C. or D.C. power supply. To change the position of the switch, remove the screw in the locking bracket and move the end of the bracket to the other position as marked on the chassis. Replace the screw so as to lock the switch in the new position.
The receiver will operate satisfactorily on either A.C. or D.C. with the switch in the D.C. position, but the performance of the receiver will be greatly improved with the switch in the A.C. position when being operated on A.C. DO NOT OPERATE THE RECEIVER ON A D.C. POWER SUPPLY WITH THE SWITCH IN THE A.C. POSITION AS IT WILL CAUSE DAMAGE TO THE RECEIVER PARTS.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits may be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the fidelity control knob to the left (NORMAL).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning E-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC," "ANT" and "R-F" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" and "R-F" trimmers. **DO NOT READJUST THE "OSC" TRIMMER.**

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 33, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

Shunt Alignment Series Alignment	50
American Broadcast Band (BLUE) 1700 Kilocycles	51A
Police Band (RED) 6000 Kilocycles	51B
High-Frequency Band (GREEN) 18000 Kilocycles	51C

CROSLY RADIO CORP.

MODEL 736
Schematic, Voltage

nals between the frequencies of approximately 440 and 480 Kilocycles may be reduced so that they are not objectionable if not entirely eliminated from over riding station being received.
It is a three band receiver and the dial is divided into three sections as follows:
(American Broadcast Band)
(Police and Amateurs)
(High Frequency Band)

SPECIFICATIONS

The Crosley Receiver Model 736 is a seven tube superheterodyne radio designed to operate on an ALTERNATING CURRENT power supply. It incorporates a WAVE-TRAP in its construction so that interfering signals between the frequencies of approximately 440 and 480 Kilocycles may be reduced so that they are not objectionable if not entirely eliminated from over riding station being received.

- BLUE 540-1800 Kilocycles (American Broadcast Band)
- RED 1.8- 6.0 Megacycles (Police and Amateurs)
- GREEN 6.0- 18.0 Megacycles (High Frequency Band)

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger - not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6AB tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles. (e) Adjust both trimmers located on top of the 3rd I-F Transformer for maximum output.

(f) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output.

(g) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(h) Check operations (e), (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .0002 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the im-

age frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 13, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

Signal Input Frequencies:

Band	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	800 Kilocycles
Police Band (RED)	6000 Kilocycles	6000 Kilocycles
High-Frequency Band (GREEN)	18000 Kilocycles	18000 Kilocycles

TO ADJUST WAVE TRAP

Connect the output of the signal generator through an .02 mfd. condenser to the ANT. terminal on the chassis and the other lead to GND. terminal.

(a) Adjust signal generator to frequency of interfering signal.

(b) Set station selector to approximately 650 Kilocycles with the band selector in the Broadcast position.

(c) Adjust Wave Trap trimmer (Item 12, Fig. 2) to minimum signal.

For simple adjustment tune-in station with maximum interference and adjust Wave Trap Trimmer for minimum interference.

SPECIFICATIONS

The Crosley Model 1026 radio is a ten-tube super-heterodyne receiver and is available either with a standard 110 volt—60 cycle power transformer or with a universal power transformer.

The tubes used are 6K7 R-F Amplifier, 6A8 Modula-

tor, 6C5 Oscillator, 6K7 I-F Amplifier, 6R7 Detector and 1st Audio Amplifier, 6C5 2nd Audio Amplifier, two 6N6 Output, 5Z4 Rectifier and the newly developed Auto-Expressionator or Volume Expander tube.

The tuning range of the receiver is from 540 to 19000 Kilocycles and is divided into three bands

MODEL 1026

Alignment Notes

CROSLLEY RADIO CORP.

UNIVERSAL POWER TRANSFORMER

The Model 1026 chassis for use on other than 110 volts -60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycles or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis, locate the terminal strip on the bottom of the power transformer and locate the wire leading from the power switch to the terminal strip. After careful measurement of the maximum values of line voltage, unsolder the wire described above, from the lug on the terminal strip and solder it to the correct lug. The correct lug will be the one marked so as to cover or nearly cover the maximum line voltage. **THE MAXIMUM LINE VOLTAGE SHOULD NOT EXCEED THE HIGHEST VOLTAGE STAMPED ON THE TERMINAL STRIP BESIDE THE LUG TO BE USED BY MORE THAN 3%.**

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, Illustration No. 65, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

PHONOGRAPH PICKUP

Chassis equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole-single throw switch to these terminals as shown in Fig. 7.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt 500 volt D.-C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A.-C. voltmeter. Readings may vary plus or minus 10% of values given.

Aligning R.-F. Amplifier.

The R.-F. amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R.-F. amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a 0.0025 mfd. condenser must be connected in series with the output lead of the signal generator and for the High-Frequency Band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated for each adjustment.

(a) Adjust the "OSC.", "R.F." and "ANT." shunt trimmers in the order given for maximum output. Re-adjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R.F." and "ANT." trimmers in the order given. **DO NOT READJUST THE "OSC." TRIMMER.**

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 32Y and 32Z Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies:

American Broadcast Band (BLUE)
Police Band (RED)
High-Frequency Band (GREEN)

Exact Aligned Series Aligned
(BLUE) 1700 Kc. 600 Kc.
(RED) 8000 Kc. 2600 Kc.
(GREEN) 18000 Kc.

II. Oscilloscope Method.

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I.-F. amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. **KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the terminal marked "P" of the 6K7 tube. (Be sure the oscilloscope is protected from D. C. by connecting a condenser .1 to .05 mf. in series with the lead connected to the plate of the 6K7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles. See instructions supplied with signal generator and oscilloscope.

(e) Close the middle trimmer condenser of the 2nd. I.-F. transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force adjustment screw).

(f) Adjust the top trimmer (Sec) of the 2nd. I.-F. transformer so that the nose of the selectivity curve is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(g) Adjust the bottom trimmer (Pri) of the 2nd. I.-F. transformer for maximum amplitude of the selectivity curve on resonance line (R).

(h) Reduce the output of the signal generator and adjust the middle trimmer of the 2nd. I.-F. transformer for maximum amplitude and symmetry of the selectivity curve about the resonance line.

NOTE: Keep the base of the selectivity curve centered on the transparent scale from -15 to +15 and keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(i) Readjust the bottom trimmer of the 2nd. I.-F. transformer for maximum symmetry and amplitude.

(j) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(k) Open the middle trimmer of the 1st. I.-F. transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(l) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I.-F. transformer for maximum symmetry and amplitude.

(m) Adjust the bottom trimmer of the 1st. I.-F. transformer for maximum amplitude.

(n) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I.-F. transformer for maximum symmetry and amplitude.

(o) Carefully repeat operations (h), (i) and (n) for more accurate adjustment.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I.-F. Amplifier to 450 Kilocycles

The I.-F. amplifier employs two triple-tuned I.-F. transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I.-F. amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

I. Conventional Method--

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf. or larger, condenser--not electrolytic--to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I.-F. Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis. **KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 2nd. I.-F. transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force the adjustment screw).

(f) Adjust the top trimmer and then the bottom trimmer (Sec. & Pri) of the 2nd. I.-F. transformer for maximum output. **ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.**

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st. I.-F. transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st. I.-F. transformer for maximum output.

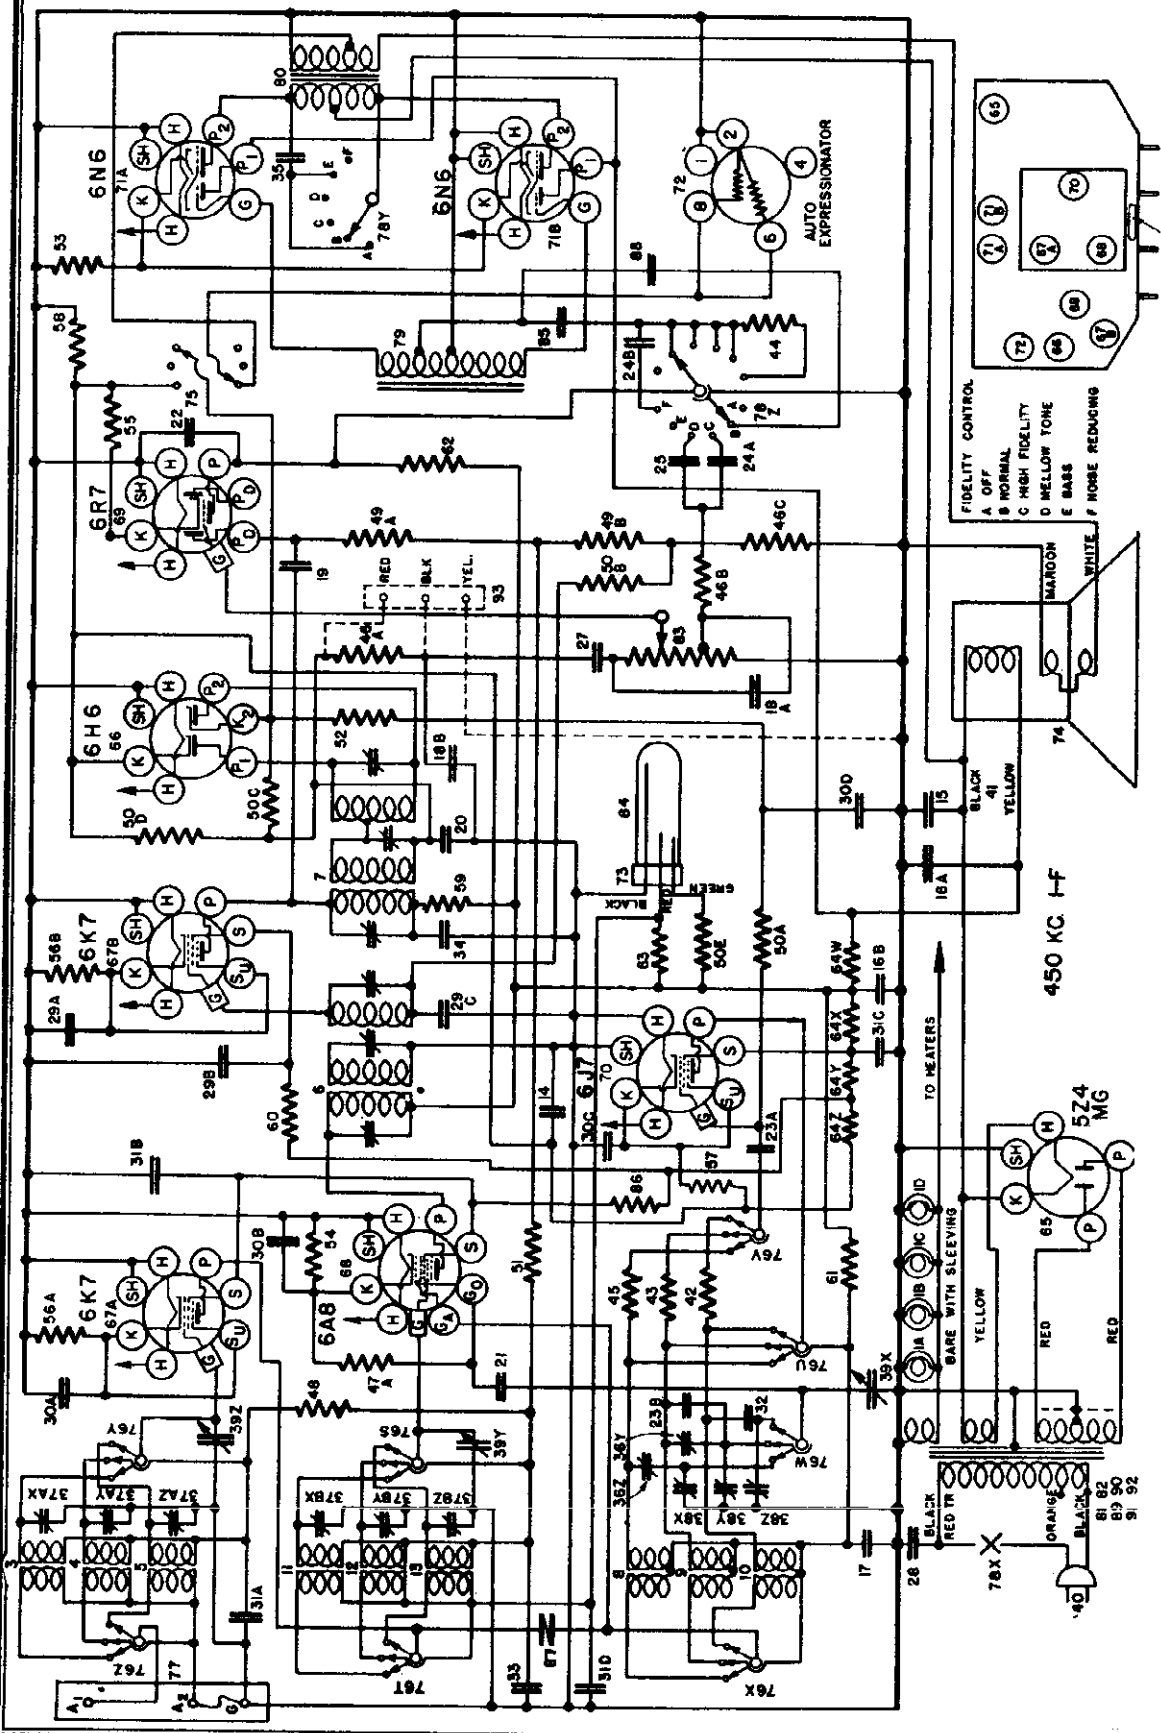

(j) Transfer the output lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(k) Adjust the middle trimmer of the 2nd. I.-F. transformer by opening until maximum output is obtained. **DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.**

(l) Adjust the middle trimmer of the 1st. I.-F. transformer by closing until maximum output is obtained. **DO NOT READJUST TOP AND BOTTOM TRIMMERS.**

50 CYCLE POWER TRANSFORMER
ADJUSTMENT

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-260 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primary, according to the line voltage the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

Fig. 7. Phonograph Pickup

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, item No. 72, Fig. 1, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music, which tends to compensate for the electrical limitations of broadcasting equipment.

MODEL 1126
Alignment Notes

CROSLLEY RADIO CORP.

ALIGNMENT PROCEDURE

This model receiver should be turned on and allowed to "warm-up" for about 15 minutes before aligning its circuits.

It is a High Fidelity receiver and in order to secure maximum performance the alignment should be done with precision instruments. The alignment condensers should not be re-adjusted just to determine if they are properly tuned. Fig. 5, shows the selectivity curve of a receiver whose I-F amplifier was slightly mistuned while Fig. 6, shows a curve made from actual measurements of a receiver employing a triple-tuned I-F amplifier which was properly aligned with the use of a FREQUENCY MODULATED R-F signal generator and an oscilloscope.

The alignment of the AFC circuit may be checked by means of a modulated signal generator and output meter as follows:

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf. or larger, condenser—not electrolytic—to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .00025 mf. condenser to the top cap of the 6A8 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis.

(c) Rotate the Phantom Control to the left-hand position (NORMAL).

(d) Adjust the frequency of the signal generator in the region of 450 kilocycles for maximum reading on the output meter.

(e) Without altering the connections or adjustments of the signal generator or output meter connect an antenna to the antenna terminal "A1" and tune-in a local broadcasting station. Turn off modulation of signal generator. Adjust station selector slightly for zero beat.

(f) Rotate the Phantom Control to the Mystic Hand position and listen to the beat note. If the note is less than 200 cycles, or the equivalent of some tone below middle C on the piano, the AFC alignment is satisfactory.

(g) If the beat note is higher than middle C re-alignment is necessary.

(h) In cases where the beat note is not more than about two octaves above middle C or from 1000 to 1500 cycles the AFC circuit may be aligned for zero beat by making a slight adjustment of the top trimmer condenser on the 2nd I-F transformer. This circuit is very critical and a slight adjustment will produce a great change in the beat note.

(i) Where the AFC is considerably out of alignment as evidenced by a beat note of higher than 1500 cycles the standard alignment procedure outlined below should be followed.

TUNING I-F AMPLIFIER

I. Conventional Method.

(a)

(b) Check the 6J7 cathode bias which should be approximately 6.5 volts with no signal applied.

(c) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the "GND" terminal of the receiver chassis.

(d) Set the band selector switch to the Broadcast Band and route the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control all the way to the right (clockwise).

(e) Turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(f) Set the signal generator to 450 kilocycles.

(g) Adjust the middle trimmer and then the bottom trimmer of the 2nd I-F transformer for maximum reading on the output meter. Caution: do not attempt to adjust the top trimmer at this time. ALWAYS USE THE LOWEST GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(h) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator.

(i) Open the middle trimmer of the 1st I-F transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(j) Adjust the top trimmer, and then the bottom trimmer of the 1st I-F transformer for maximum reading on the output meter.

(k) Adjust the middle trimmer of the 1st I-F transformer by closing until maximum reading is obtained on the output meter.

(l) Transfer the output lead of the signal generator from the 6A8 tube to the antenna terminal "A1" of the receiver and recheck the adjustment of the bottom trimmer of the 1st I-F transformer.

(m) To adjust the AFC system it will be necessary to transfer the output lead of the signal generator back to the top cap of the 6K7 I-F amplifier tube. The .02 mf. condenser should still be connected in series with this lead.

(n) Insert a 0.5 millimeter in series with the cathode circuit of the 6J7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(o) Turn the Phantom Control to the MYSTIC HAND position and without changing the output of the signal generator, adjust the top trimmer condenser of the 2nd I-F transformer so that the reading of the 0.5 millimeter is the same as was recorded with the Phantom Control in the NORMAL position. This value of current will be obtained with the trimmer closed, with the trimmer open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used. An insulated screw

driver should be used in adjusting the AFC trimmer condenser.

(p) As a final check on the AFC adjustment, disconnect the test equipment and tune-in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC "ON" and "OFF." If reception is the same in both positions and will automatically tune-in strong stations within approximately plus or minus 10 kilocycles of the station selector setting with AFC "ON," the AFC is properly aligned. If distortion is noted and the receiver will not automatically tune-in stations as desired, the AFC alignment should be rechecked.

II. Oscilloscope Method.

(a) Connect the output of a FREQUENCY MODULATED R-F signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. KEEP THE GENERATOR LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The "High" side should be connected to the plate of the 6R7 tube and the "low" side should be connected to the receiver chassis. Be sure the oscilloscope is protected from D.C. by connecting a condenser: 1 mf. to .05 mf., in series with the lead of the 6R7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(d) Set the signal generator to 450 kilocycles. See instructions supplied with signal generator and oscilloscope.

(e) Adjust the middle trimmer of the 2nd I-F transformer so that the nose of the selectivity curve is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(f) Adjust the bottom trimmer of the 2nd I-F transformer for maximum amplitude of the selectivity curve on resonance axis (R).

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator.

(h) Open the middle trimmer of the 1st I-F transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Increase the output of the signal generator and adjust the top trimmer of the 1st I-F transformer for maximum symmetry and amplitude.

(j) Adjust the bottom trimmer of the 1st I-F transformer for maximum amplitude.

(k) Reduce the output of the signal generator and adjust the middle trimmer of the 1st I-F transformer for maximum symmetry and amplitude.

(l) Carefully repeat operations (f) and (k) for

more accurate adjustments.

Aligning R-F Amplifier.
The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal "A1" of the receiver. For the BLUE and RED bands a .00025 mf. condenser must be connected in series with the output lead of the signal generator and for the high frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be skunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated in "C" below for each adjustment.

(a) Adjust the "OSC.", "R-F" and "ANT" skunt trimmers in the order given for maximum output. Re-adjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When skunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 39Z and 39Y—Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output is obtained.

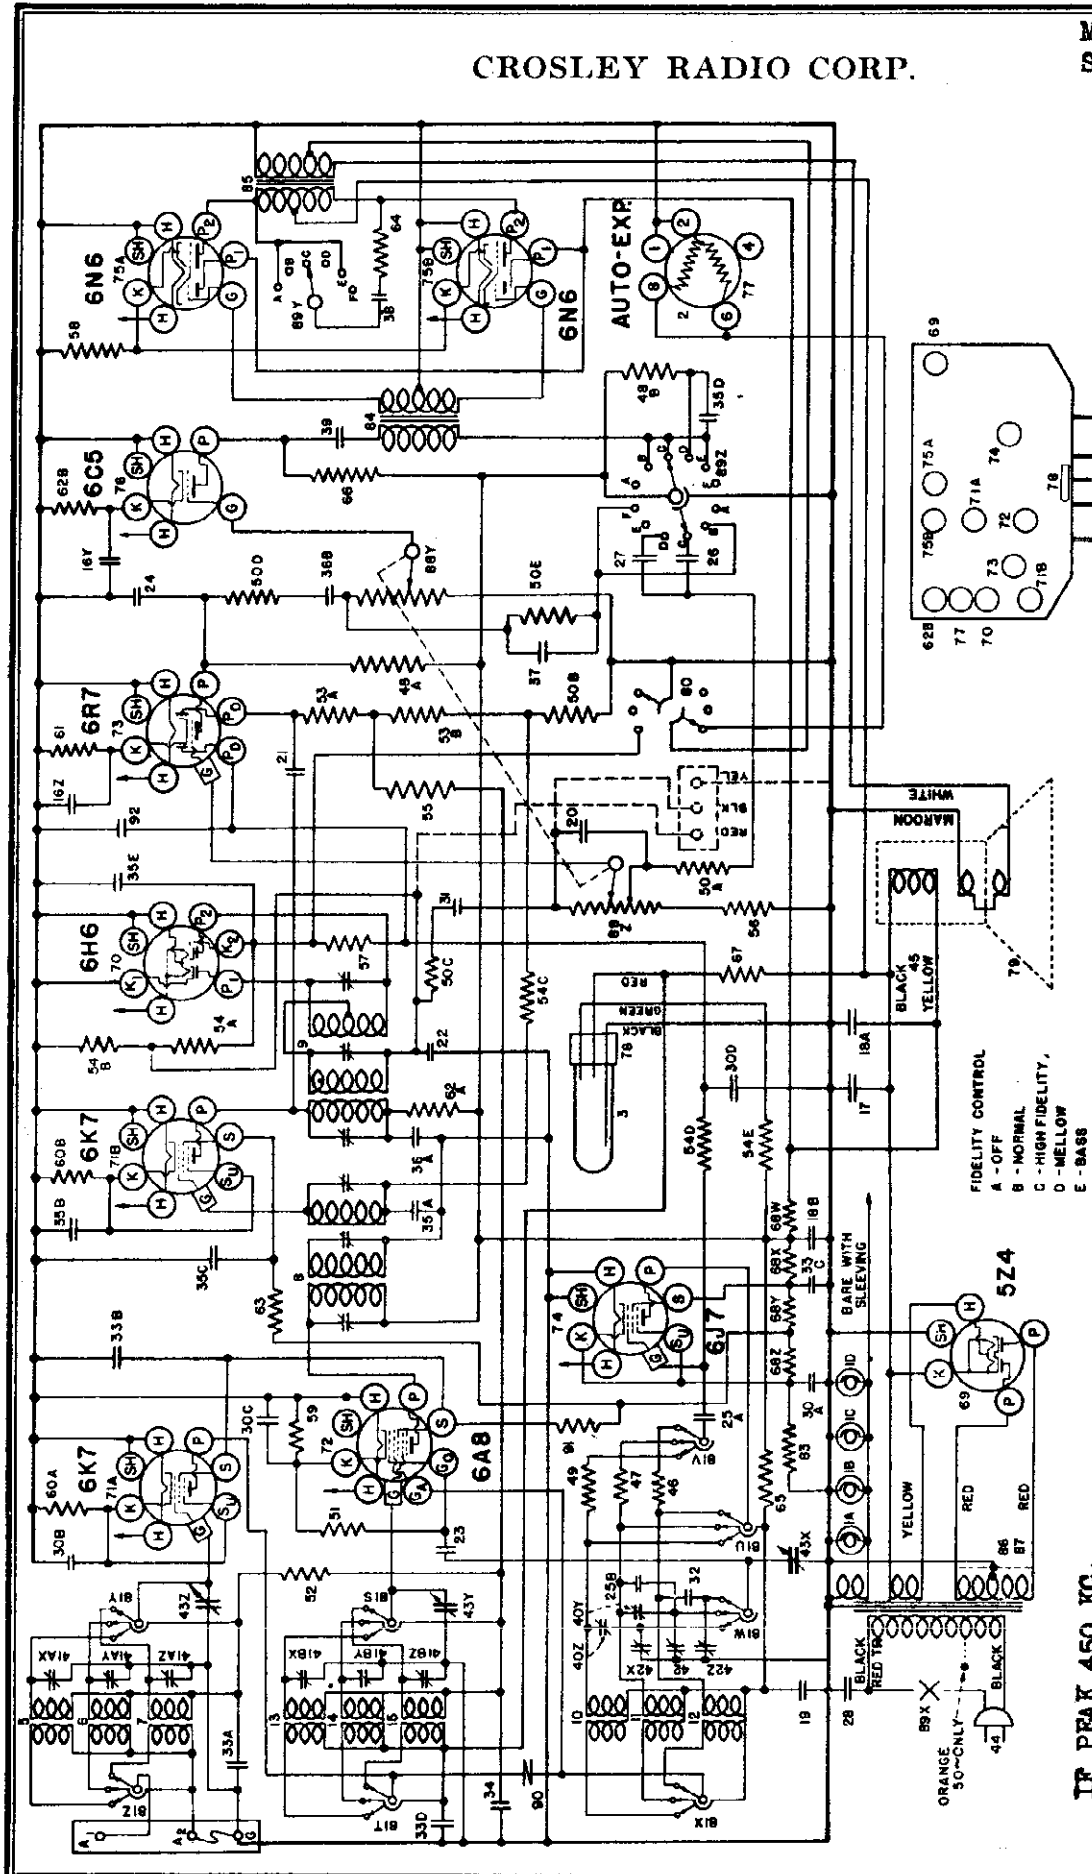

PHANTOM CONTROL

The Phantom Control permits the listener to use the Mystic Hand (Automatic Frequency Control) and the Auto-Expressionator as desired. The various positions of the control are shown on an illuminated indicator on the dial.

The receiver may be operated with normal power output and fidelity, such as would ordinarily be desired in the average home, with the control in the NORMAL position.

The Mystic Hand automatically tunes the receiver accurately to the strongest signal within a frequency range of approximately 10 kilocycles of the station selector setting.

CROSLLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 1216 radio is a Twelve-tube receiver featuring High Fidelity, Volume Expansion which is accomplished by the Auto-Expressionator tube and Automatic Frequency Control which is known as the Mystic Hand.

The tubes used are 6K7 R-F Amplifier, 6A8 Oscillator-Modulator, 6J7 AFC Control, 6K7 I-F Amplifier, 6H6 AFC Detector, 6R7 AVC Diode and A-F Amplifier 6C5 A-F Driver, two 6N6 Output, 5Z4 Rectifier, W41187 Auto-Expressionator and W42419A Neon Tuning Tube.

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, item No. 77, Fig. 1, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music, which tends to compensate for the electrical limitations of broadcasting equipment.

Fig. 4 Front View—1216

**MODEL 1216
Alignment
Notes**

CROSLLEY RADIO CORP.

in the order given. **DO NOT READJUST THE "OSC" TRIMMER.** When about aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, "Osc. Series"—Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector trimmer for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output is obtained.

PHANTOM CONTROL

The Phantom Control permits the listener to use the Mystic Hand (Automatic Frequency Control) and the Auto-Expressionist as desired. The various positions of the control are shown on an illuminated indicator on the dial.

The receiver may be operated with normal power output and fidelity, such as would ordinarily be desired in the average home, with the control in the NORMAL position.

The Mystic Hand automatically tunes the receiver accurately to the strongest signal within a frequency range of approximately 10 kilocycles of the station selector setting.

50 CYCLE POWER TRANSFORMER ADJUSTMENT

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-260 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primarily, according to the line voltage the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. meter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A.C. voltmeter. Readings may vary plus or minus 10% of values given.

ness to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place. **KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.**

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The "High" side should be connected to the plate of the 6R7 tube and the "Low" side should be connected to the receiver chassis. Be sure the oscilloscope is protected from D.C. by connecting a condenser, .1 mf. to .05 mf., in series with the lead of the 6R7 tube.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(d) Set the signal generator to 450 kilocycles. See instructions supplied with signal generator and oscilloscope.

(e) Adjust the middle trimmer of the 2nd I.F. transformer so that the nose of the selectivity curve is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(f) Adjust the bottom trimmer of the 2nd I.F. transformer for maximum amplitude of the selectivity curve on resonance axis (R).

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I.F. transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I.F. transformer for maximum reading on the output meter.

(j) Adjust the middle trimmer of the 1st I.F. transformer by closing until maximum reading is obtained on the output meter.

(k) Transfer the output lead of the signal generator from the 6A8 tube to the antenna terminal "A1" of the receiver and recheck the adjustment of the bottom trimmer of the 1st I.F. transformer.

(l) To adjust the AFC system it will be necessary to transfer the output lead of the signal generator back to the top cap of the 6K7 I.F. amplifier tube. The .02 mf. condenser should still be connected in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(m) Insert a 0.5 millimeter in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(n) Turn the Phantom Control to the MYSTIC HAND position and without changing the output of the signal generator, adjust the top trimmer of the 2nd I.F. transformer so that the reading of the 0.5 milliammeter is the same as was recorded with the Phantom Control in the NORMAL position. This value of current will be obtained with the trimmer closed, with the trimmer open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used. An insulated screw driver should be used in adjusting the AFC trimmer condenser.

(o) As a final check on the AFC adjustment, disconnect the test equipment and tune-in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC "ON" and "OFF". If reception is the same in both positions and will automatically tune-in strong stations within approximately plus or minus 10 kilocycles of the station selector setting with AFC "ON", the AFC is properly aligned. If distortion is noted and the receiver will not automatically tune-in stations as described, the AFC alignment should be rechecked.

(a) Adjust the "OSC", "R.F." and "ANT" shunt trimmers in the order given for maximum output. Realign the station selector slightly so that the generator signal is tuned-in with maximum output and then check

(d) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control all the way to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(e) Set the signal generator to 450 kilocycles.

(f) Adjust the middle trimmer and then the bottom trimmer of the 2nd I.F. transformer for maximum reading on the output meter. Caution: do not attempt to adjust the top trimmer at this time. **ALWAYS USE THE LOWEST GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.**

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I.F. transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I.F. transformer for maximum reading on the output meter.

(j) Adjust the middle trimmer of the 1st I.F. transformer by closing until maximum reading is obtained on the output meter.

(k) Transfer the output lead of the signal generator from the 6A8 tube to the antenna terminal "A1" of the receiver and recheck the adjustment of the bottom trimmer of the 1st I.F. transformer.

(l) To adjust the AFC system it will be necessary to transfer the output lead of the signal generator back to the top cap of the 6K7 I.F. amplifier tube. The .02 mf. condenser should still be connected in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(m) Insert a 0.5 millimeter in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(n) Turn the Phantom Control to the MYSTIC HAND position and without changing the output of the signal generator, adjust the top trimmer of the 2nd I.F. transformer so that the reading of the 0.5 milliammeter is the same as was recorded with the Phantom Control in the NORMAL position. This value of current will be obtained with the trimmer closed, with the trimmer open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used. An insulated screw driver should be used in adjusting the AFC trimmer condenser.

(o) As a final check on the AFC adjustment, disconnect the test equipment and tune-in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC "ON" and "OFF". If reception is the same in both positions and will automatically tune-in strong stations within approximately plus or minus 10 kilocycles of the station selector setting with AFC "ON", the AFC is properly aligned. If distortion is noted and the receiver will not automatically tune-in stations as described, the AFC alignment should be rechecked.

(a) Connect the output meter as outlined above in Fig. 6. Check the 6I7 cathode bias which should be approximately 65 volts with no signal applied.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the "GND" terminal of the receiver chassis.

(c) Rotate the Phantom Control to the left-hand position (NORMAL).

(d) Adjust the frequency of the signal generator in the region of 450 kilocycles for maximum reading on the output meter.

(e) Without altering the connections or adjustments of the signal generator or output meter, connect an antenna to the antenna terminal "A1" and tune-in a local broadcasting station. Turn off modulation of signal generator. Adjust station selector slightly for zero beat.

(f) Rotate the Phantom Control to the Mystic Hand position and listen to the beat note. If the note is less than 200 cycles, or the equivalent of some tone below middle C on the piano, the AFC alignment is satisfactory.

(g) If the beat note is higher than middle C re-alignment is necessary.

(h) In cases where the beat note is not more than about two octaves above middle C or from 1000 to 1500 cycles the AFC circuit may be aligned for zero beat by making a slight adjustment of the top trimmer condenser on the 2nd I.F. transformer. This circuit is very critical and a slight adjustment will produce a great change in the beat note.

(i) Where the AFC is considerably out of alignment as evidenced by a beat note of higher than 1500 cycles the standard alignment procedure outlined below should be followed.

TUNING I.F. AMPLIFIER

(a) Connect the output meter as outlined above in Fig. 6. Check the 6I7 cathode bias which should be approximately 65 volts with no signal applied.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the "G" terminal of the receiver chassis.

(d) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control all the way to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(e) Set the signal generator to 450 kilocycles.

(f) Adjust the middle trimmer and then the bottom trimmer of the 2nd I.F. transformer for maximum reading on the output meter. Caution: do not attempt to adjust the top trimmer at this time. **ALWAYS USE THE LOWEST GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.**

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I.F. transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I.F. transformer for maximum reading on the output meter.

(j) Adjust the middle trimmer of the 1st I.F. transformer by closing until maximum reading is obtained on the output meter.

(k) Transfer the output lead of the signal generator from the 6A8 tube to the antenna terminal "A1" of the receiver and recheck the adjustment of the bottom trimmer of the 1st I.F. transformer.

(l) To adjust the AFC system it will be necessary to transfer the output lead of the signal generator back to the top cap of the 6K7 I.F. amplifier tube. The .02 mf. condenser should still be connected in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(m) Insert a 0.5 millimeter in series with the cathode circuit of the 6I7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(n) Turn the Phantom Control to the MYSTIC HAND position and without changing the output of the signal generator, adjust the top trimmer of the 2nd I.F. transformer so that the reading of the 0.5 milliammeter is the same as was recorded with the Phantom Control in the NORMAL position. This value of current will be obtained with the trimmer closed, with the trimmer open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used. An insulated screw driver should be used in adjusting the AFC trimmer condenser.

(o) As a final check on the AFC adjustment, disconnect the test equipment and tune-in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC "ON" and "OFF". If reception is the same in both positions and will automatically tune-in strong stations within approximately plus or minus 10 kilocycles of the station selector setting with AFC "ON", the AFC is properly aligned. If distortion is noted and the receiver will not automatically tune-in stations as described, the AFC alignment should be rechecked.

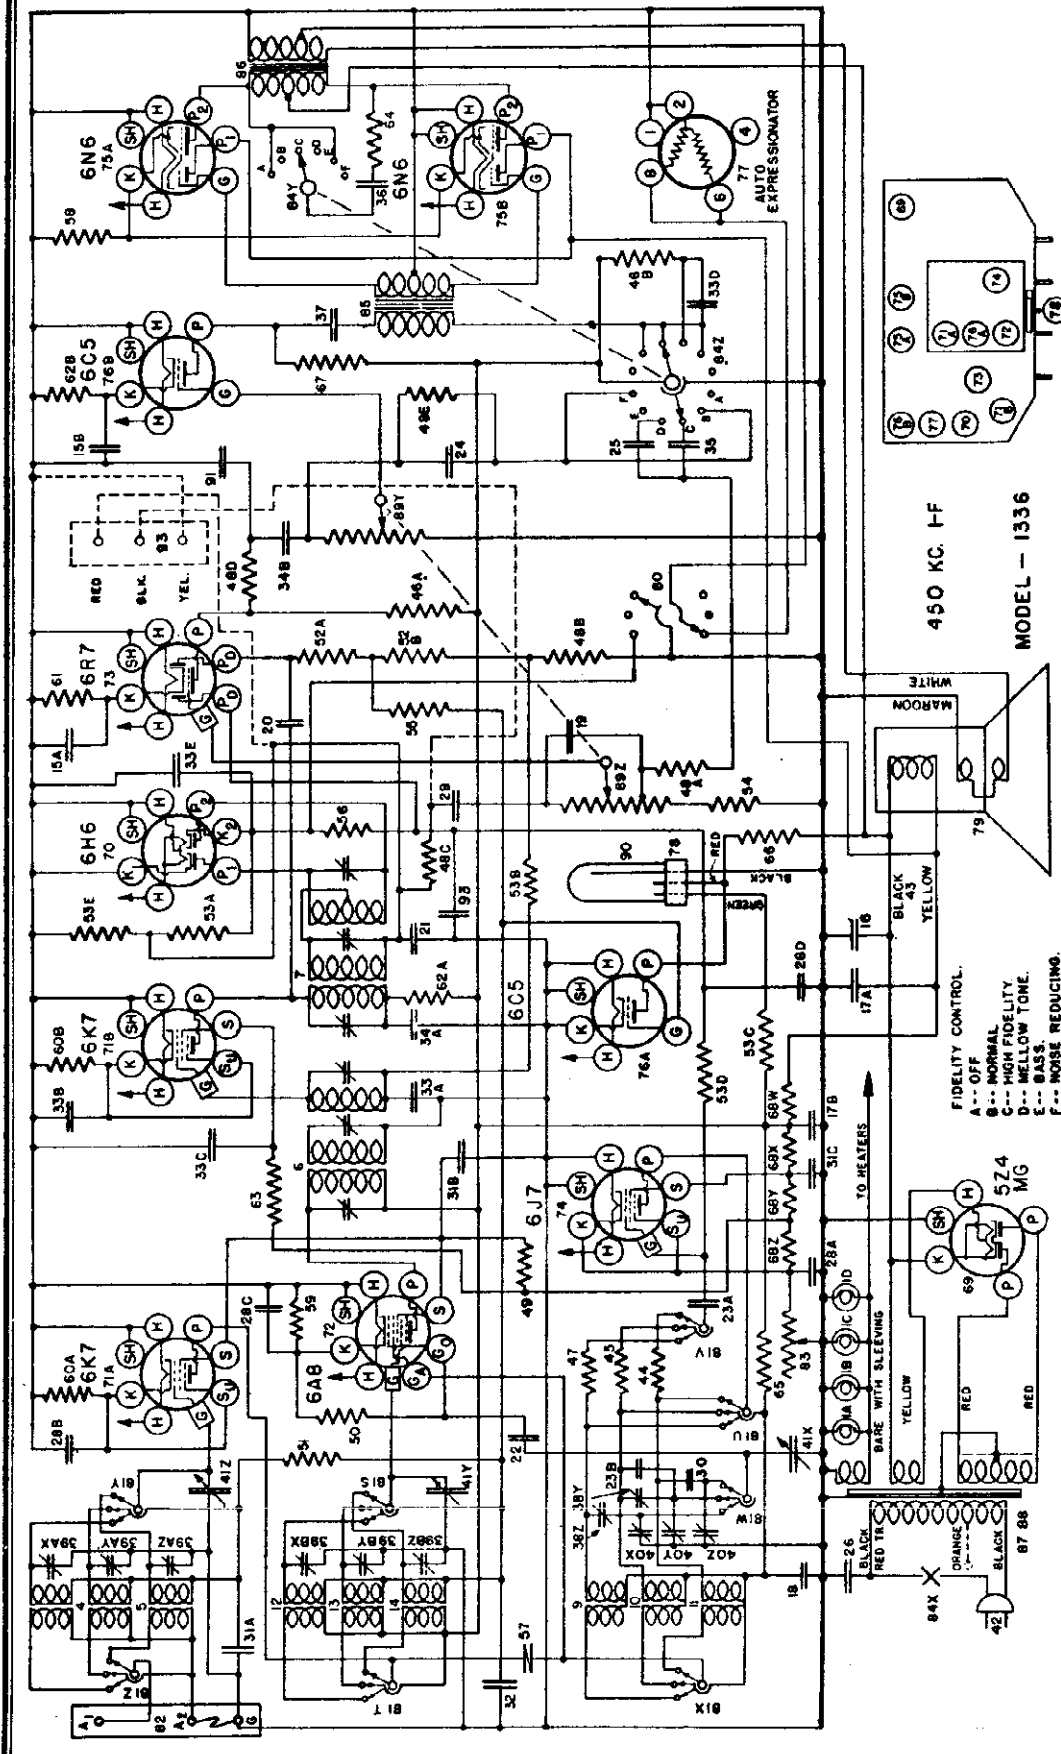

II. Oscilloscope Method

(a) Connect the output meter as outlined above in Fig. 6. Check the 6I7 cathode bias which should be approximately 65 volts with no signal applied.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the "G" terminal of the receiver chassis.

CROSLLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 1336 radio is a Thirteen-tube receiver featuring High Fidelity, Volume Expansion which is accomplished by the Auto-Expressionator tube and Automatic Frequency Control which is known as the Mystic Hand.

The tubes used are 6K7 R-F Amplifier, 6A8 Oscilla-

tor-Modulator, 6J7 AFC Control, 6K7 I-F Amplifier, 6H6 AFC Detector, 6R7 AVC Diode and A-F Amplifier, 6C5 A-F Driver, two 6N6 Output, 6C5 Tuning Indicator, Amplifier, 5Z4 Rectifier, W41187 Auto-Expressionator, and W42419A Neon Tuning Indicator Tube.

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, item No. 77, Fig. 1, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music, which tends to compensate for the electrical limitations of broadcasting equipment.

MODEL 1336

Alignment, Notes

CROSLEY RADIO CORP.

Each band should first be shut aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated in "C" below for each adjustment.

(a) Adjust the "OSC", "R-F", and "ANT" shunt trimmers in the order given for maximum output. Re-adjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check in the order given. **DO NOT READJUST THE "OSC" TRIMMER.**

NOTE: When shut aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, "osc. series" Fig. 7, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted, rotate the station selector back and forth slightly until no further improvement in output is obtained.

50 CYCLE POWER TRANSFORMER ADJUSTMENT

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-260 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primary, according to the line voltage the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

PHANTOM CONTROL

The Phantom Control permits the listener to use the Mystic Hand (Automatic Frequency Control) and the Auto-Expressionist as desired. The various positions of the control are shown on an illuminated indicator on the dial.

The receiver may be operated with normal power output and fidelity, such as would ordinarily be desired in the average home, with the control in the NORMAL position.

The Mystic Hand automatically tunes the receiver accurately to the strongest signal within a frequency range of approximately 10 kilocycles of the station selector setting.

tions within approximately plus or minus 10 kilocycles of the station selector setting with AFC "ON", the AFC is properly aligned. If distortion is noted and the receiver will not automatically tune-in stations as described, the AFC alignment should be rechecked.

II. Oscilloscope Method.
(a) Connect the output of a FREQUENCY MODULATED R-F signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. KEEP THE GENERATOR LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The "High" side should be connected to the plate of the 6R7 tube and the "Low" side should be connected to the receiver chassis. (Be sure the oscilloscope is protected from D.C. by connecting a condenser, .1 mfd. to .05 mfd., in series with the lead of the 6R7 tube.)

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(d) Set the signal generator to 450 kilocycles. See instructions supplied with signal generator and oscilloscope.

(e) Adjust the middle trimmer of the 2nd I-F transformer so that the nose of the selectivity curve is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(f) Adjust the bottom trimmer of the 2nd I-F transformer for maximum amplitude of the selectivity curve on resonance axis (R).

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I-F transformer three or four turns of the adjustment screw. Care should be taken that the adjustment screw does not become dislodged from the nut.

(i) Increase the output of the signal generator and adjust the top trimmer of the 1st I-F transformer for maximum symmetry and amplitude.

(j) Adjust the bottom trimmer of the 1st I-F transformer for maximum amplitude.

(k) Reduce the output of the signal generator and adjust the middle trimmer of the 1st I-F transformer for maximum symmetry and amplitude.

(l) Carefully repeat operations (i) and (k) for more accurate adjustments.

ALIGNING R-F AMPLIFIER

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal "A1" of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high frequency band a 400 ohm carbon resistor should be used in place of the condenser.

signal applied, by means of the variable control item, No. B3, Fig. 3.

(c) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the "G" terminal of the receiver chassis.

(d) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control all the way to the right (clockwise), turn the fidelity control to HIGH FIDELITY and the Phantom Control to NORMAL.

(e) Set the signal generator to 450 kilocycles.

(f) Adjust the middle trimmer and then the bottom trimmer of the 2nd I-F transformer for maximum reading on the output meter. Caution: do not attempt to adjust the top trimmer at this time. ALWAYS USE THE LOWEST GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I-F transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut.)

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I-F transformer for maximum reading on the output meter.

(j) Adjust the middle trimmer of the 1st I-F transformer by closing until maximum reading is obtained on the output meter.

(k) Transfer the output lead of the signal generator from the 6A8 tube to the antenna terminal "A1" of the receiver and recheck the adjustment of the bottom trimmer of the 1st I-F transformer.

(l) To adjust the AFC system it will be necessary to transfer the output lead of the signal generator back to the top cap of the 6K7 I-F amplifier tube. The .02 mfd. condenser should still be connected in series with this lead.

(m) Insert a 0.5 millimeter in series with the cathode circuit of the 6J7 tube and with a strong 450 kilocycle signal from the signal generator, the reading of the cathode current should be recorded.

(n) Turn the Phantom Control to the MYSTIC HAND position and without changing the output of the signal generator, adjust the top trimmer condenser of the 2nd I-F transformer so that the reading of the 0.5 millimeter is the same as was recorded with the Phantom Control in the NORMAL position. This value of current will be obtained with the trimmer closed, with the trimmer open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used. An insulated screw driver should be used in adjusting the AFC trimmer condenser.

(o) As a final check on the AFC adjustment, disconnect the test equipment and tune-in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC "ON" and "OFF". If reception is the same in both positions and will automatically tune-in strong sta-

This model receiver should be turned-on and allowed to "warm-up" for about 15 minutes before aligning its circuits.

It is a High Fidelity receiver and in order to secure maximum performance the alignment should be done with precision instruments. The alignment condensers should not be readjusted to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mistuned while Fig. 6 shows a curve made from actual measurements of a receiver employing a triple-tuned I-F amplifier which was properly aligned with the use of a FREQUENCY MODULATED R-F signal generator and an oscilloscope.

The alignment of the AFC circuit may be checked by means of a modulated signal generator and output meter as follows:

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mfd. or larger, condenser—not electrolytic to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .00025 mfd. condenser to the top cap of the 6A8 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis.

(c) Rotate the Phantom Control to the left-hand position (NORMAL).

(d) Adjust the frequency of the signal generator in the region of 450 kilocycles for maximum reading on the output meter.

(e) Without altering the connections or adjustments of the signal generator or output meter, connect an antenna to the antenna terminal "A1" and tune-in a local broadcasting station. Turn off modulation of signal generator. Adjust station selector slightly for zero beat.

(f) Rotate the Phantom Control to the MYSTIC HAND position and listen to the beat note. If the note is less than 200 cycles, or the equivalent of some tone below middle C on the piano, the AFC alignment is satisfactory.

(g) If the beat note is higher than middle C re-alignment is necessary.

(h) In cases where the beat note is not more than about two octaves above middle C or from 1000 to 1500 cycles the AFC circuit may be aligned for zero beat by making a slight adjustment of the top trimmer condenser on the 2nd I-F transformer. This circuit is very critical and a slight adjustment will produce a great change in the beat note.

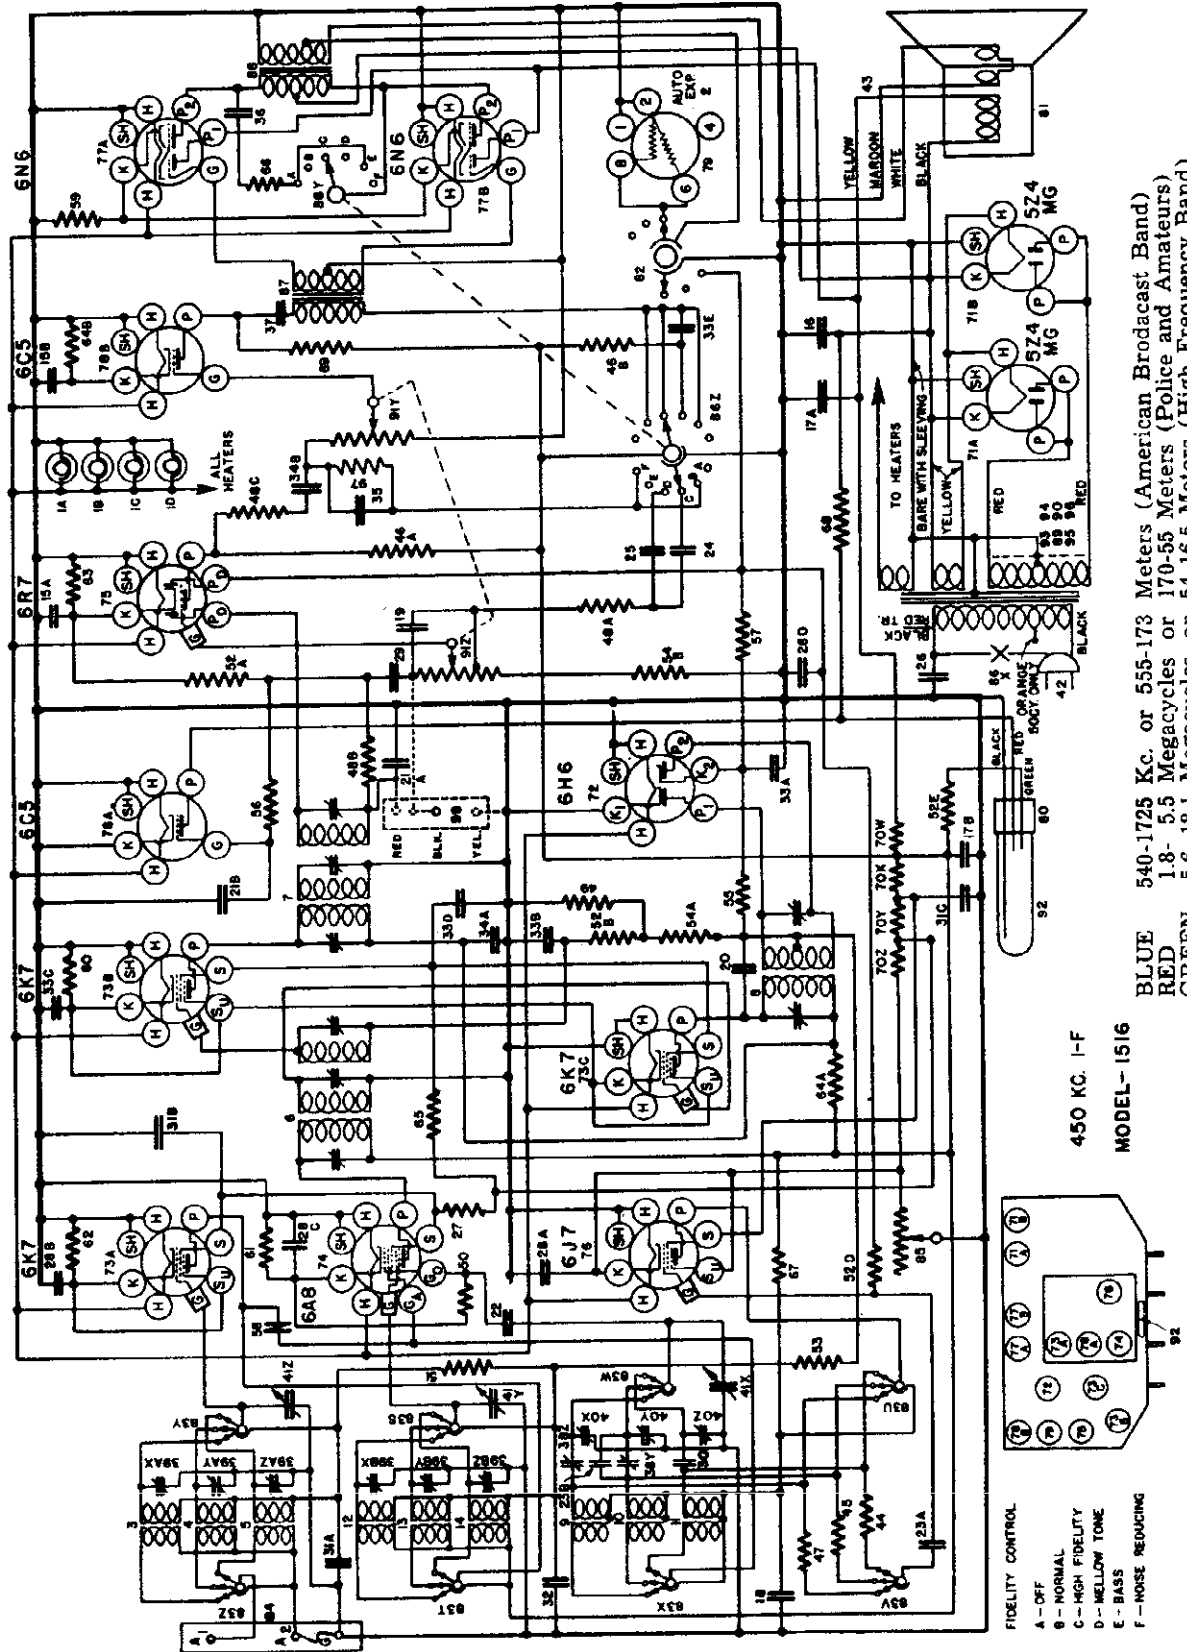

(i) Where the AFC is considerably out of alignment as evidenced by a beat note of higher than 1500 cycles the standard alignment procedure outlined below should be followed.

TUNING I-F AMPLIFIER
1. Conventional Method.

(a) Connect the output meter as outlined above in

(b) Adjust the 6J7 cathode bias to 6.5 volts with no

CROSLLEY RADIO CORP.

SPECIFICATIONS

The Crosley Model 1516 radio is a fifteen-tube receiver featuring High Fidelity, Volume Expansion which is accomplished by the Auto-Expressionator tube and Automatic Frequency Control which is known as the Mystic Hand.

The tubes used are 6K7 R-F Amplifier, 6A8 Oscillator-Modulator, 6J7 AFC Control, 6K7 Signal I-F Amplifier, 6K7 AFC Diode and I-F Amplifier, 6H6 AFC Detector, 6R7 Diode and 1st A-F Amplifier, 6C5 A-F Driver, (2) 6N6 Output, (2) 5Z4 Rectifiers, 6C5 Tuning In-

icator Amplifier, W42419A Neon Tuning Indicator Tube and W-41187 Auto-Expressionator Tube.

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, item No. 79, Fig. 1, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music, which tends to compensate for the electrical limitations of broadcasting equipment.

PART LIST—MODEL 1516

50 CYCLE POWER TRANSFORMER ADJUSTMENT

Fig. 4. Front View—1516

MODEL 1516

Alignment Notes

CROSLLEY RADIO CORP.

should be used in place of the condenser.

Each band where provision is made for series alignment, should first be aligned and then the BLUE and RED bands. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated in "C" below for each adjustment.

(a) Adjust the "OSC", "R.F." and "ANT." shunt trimmers in the order given for maximum output. Re-adjust the station selector slightly so that the generator signal is tuned in with maximum output and then check in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned in at both positions but much stronger at the correct position.

(b) To align the series trimmers, "osc. series" Fig. 2, set the signal generator to the frequency indicated below and then tune in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted, rotate the station selector back and forth slightly until no further improvement in output is obtained.

(c) SIGNAL INPUT FREQUENCIES

American Broadcast Band: BLUE 1,400 Kilocycles, 600 Kilocycles
Police and Amateur Band (RED) 5,000 Kilocycles, 2000 Kilocycles
High Frequency Band (GREEN) 18,000 Kilocycles

PHANTOM CONTROL

The Phantom Control permits the listener to use the Mystic Hand (Automatic Frequency Control) and the Auto-Expressionist as desired. The various positions of the control are shown on an illuminated indicator on the dial.

The receiver may be operated with normal power output and fidelity, such as would ordinarily be desired in the average home, with the control in the NORMAL position.

The Mystic Hand automatically tunes the receiver accurately to the strongest signal within a frequency range of approximately 15 kilocycles of the station selector setting.

50 CYCLE POWER TRANSFORMER

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-250 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primary, according to the line voltage of the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

II. Oscilloscope Method.

(a) Connect the output of a FREQUENCY MODULATED R.F. signal generator through a .02 mf. condenser to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the antenna terminal of the antenna coil. LEAVE THE OTHER LEADS OF THE SCREEN GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the antenna terminal of the antenna coil and the horizontal plates to the top cap of the 6K7 tube. The binding posts marked "GND" should be connected to the chassis and the other binding post should be connected to the antenna terminal of the antenna coil. Be sure the oscilloscope is connected from D.C. by connecting a condenser, 1 mf. to .05 mf. in series with the lead connected to the plate of the 6K7 tube.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control knob to the right (ON), turn the fidelity control to NORMAL and turn the phantom control to NORMAL.

(d) Set the signal generator to 450 kilocycles. See instructions supplied with signal generator and oscilloscope.

(e) Open the middle trimmer condenser on the 2nd I.F. transformer three or four turns of the adjustment screw. (Care should be taken that the adjustment screw does not become dislodged from the nut.)

(f) Adjust the top trimmer of the 2nd I.F. transformer so that the nose of the selectivity curve is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(g) Adjust the bottom trimmer of the 2nd I.F. transformer for maximum amplitude of the selectivity curve on resonance line (R).

(h) Reduce the output of the signal generator and adjust the middle trimmer of the 2nd I.F. transformer for maximum amplitude and symmetry of the selectivity curve about the resonance line.

NOTE: Keep the base of the selectivity curve centered on the transparent scale from -15 to +15 and keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(i) Readjust the bottom trimmer of the 2nd I.F. transformer for maximum symmetry and amplitude.

(j) Transfer the output lead of the signal generator and modulator tube, leaving the tube's grid clip in place.

(k) Open the middle trimmer of the 1st I.F. transformer three or four turns of the adjustment screw from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut.)

(l) Increase the output of the signal generator and adjust the top trimmer of the 1st I.F. transformer for maximum symmetry and amplitude.

(m) Adjust the bottom trimmer of the 1st I.F. transformer for maximum amplitude.

(n) Reduce the output of the signal generator and adjust the middle trimmer of the 1st I.F. transformer for maximum symmetry and amplitude.

(o) Carefully check the alignment (b), (i) and (n) for more accurate adjustment. (See Fig. 6).

Aligning R.F. Amplifier.

The R.F. amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R.F. amplifier the output lead of the signal generator is connected to the antenna terminal, "A1" of the receiver. For the BLUE and RED bands a .00025 mf. condenser must be connected in series with the output lead of the signal generator and for the high frequency band a 400-ohm carbon resistor

the adjustment screw does not become dislodged from the nut.)

(e) Adjust the top trimmer and then the bottom trimmer (See Fig. 2) of the 2nd I.F. transformer for maximum output. Do not readjust the middle trimmer. ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6AB Osc. Mod. tube, leaving the tube's grid clip in place.

(g) Open the middle trimmer of the 1st I.F. transformer three or four turns of the adjustment screw, from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut.)

(h) Adjust the top trimmer and then the bottom trimmer of the 1st I.F. transformer for maximum output.

(i) Transfer the output lead of the signal generator from the 6AB tube to the antenna terminal, "A1" of the receiver and increase the output of the signal generator if necessary.

(j) Adjust the middle trimmer of the 2nd I.F. transformer for maximum output. (Care should be taken that the adjustment screw does not become dislodged from the nut.)

(k) Adjust the top trimmer of the 1st I.F. transformer for maximum output.

(l) To adjust the AFC system it will be necessary to remove the signal generator lead from the receiver and adjust the 6J7 cathode bias to 6.5 volts by means of the variable control. (Illustration No. 95—Fig. 3) in this cathode circuit.

(m) Turn the phantom control to the left (NORMAL) and connect the signal output lead through a .02 mf. condenser to the top cap of the 6AB oscillator-modulator tube, leaving the tube's grid clip in place.

(n) Adjust the front trimmer (plate winding) of the AFC I.F. transformer for minimum reading on the output meter. It will be necessary to retard the volume control of the receiver in order to prevent AVC action. A fairly strong LF signal will be required. (An illuminated screw driver should be used for aligning the AFC amplifier system.)

(o) Insert an 0.5 millimeter in series with the lead to the cathode terminal of the 6J7 socket and note the current reading.

(p) Turn the phantom control to its middle position and increase the output of the signal generator to approximately 100,000 microvolts.

(q) Transfer the output lead of the signal generator from the 6AB tube to the top cap of the 6K7 AFC I.F. amplifier tube, leaving the tube's grid clip in place.

(r) Adjust the rear trimmer of the AFC I.F. transformer for the same value of cathode current as obtained in (p) above. This value of current will be obtained with the trimmer closed, with it open and at some intermediate position. A very slight adjustment while in the intermediate position will cause the meter to read from 0 to 1.5 milliamperes. This is the setting that should be used.

(s) To check on the AFC adjustment, disconnect the equipment and tune in a fairly weak broadcast station in the region of 1500 kilocycles. Turn the AFC ON and OFF. If reception is the same in both positions and will automatically tune-in strong stations within approximately plus or minus 15 kilocycles of the station selector setting with the AFC ON, the AFC is properly aligned. If distortion is noted and the set will not automatically tune-in stations as described, the AFC alignment should be rechecked.

ALIGNMENT PROCEDURE

This model receiver should be turned on and allowed to "warm-up" for about 15 minutes before aligning its circuits.

It is a High Fidelity receiver and in order to secure maximum performance the alignment should be done with precision instruments. The alignment condensers should not be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I.F. amplifier was slightly mistuned while Fig. 6 shows a curve made from actual measurements which was properly aligned with the use of a FREQUENCY MODULATED R.F. signal generator and an oscilloscope.

The alignment of the AFC circuit may be checked by means of a modulated signal generator and output meter as follows:

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf. or larger, condenser—not electrolytic to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .00025 mf. condenser to the top cap of the 6AB Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis.

(c) Rotate the Phantom Control to the left-hand position (NORMAL).

(d) Adjust the frequency of the signal generator in the region of 450 kilocycles for maximum reading on the output meter.

(e) Without altering the connections or adjustments of the signal generator or output meter, connect an antenna to the antenna terminal, "A1" and tune-in a local broadcasting station. Turn off modulation of signal generator. Adjust station selector slightly for zero beat.

(f) Rotate the Phantom Control to the Mystic Hand position and listen to the beat note. If the note is less than 200 cycles, or the equivalent of some one below middle C on the piano, the AFC alignment is satisfactory.

(g) If the beat note is higher than middle C re-aligning is necessary.

(h) In cases where the beat note is not more than about two octaves above middle C or from 1000 to 1500 cycles, the AFC circuit may be aligned for zero beat by making a slight adjustment of the rear trimmer condenser on the AFC I.F. transformer (Fig. 2, item No. 8).

This circuit is very critical and a slight adjustment will produce a great change in the beat note.

(i) Where the AFC is considerably out of alignment as evidenced by a beat note of higher than 1500 cycles the standard alignment procedure outlined below should be followed.

TUNING I.F. AMPLIFIER

The I.F. amplifier employs two triple-tuned signal I.F. transformers and one double-tuned AFC I.F. transformer.

I. Conventional Method

(a) Connect the output meter and signal generator as outlined in (b) except that the signal generator should be connected through a .02 mf. condenser to the top cap of the 6K7 I.F. amplifier tube, leaving the tube's grid clip in place.

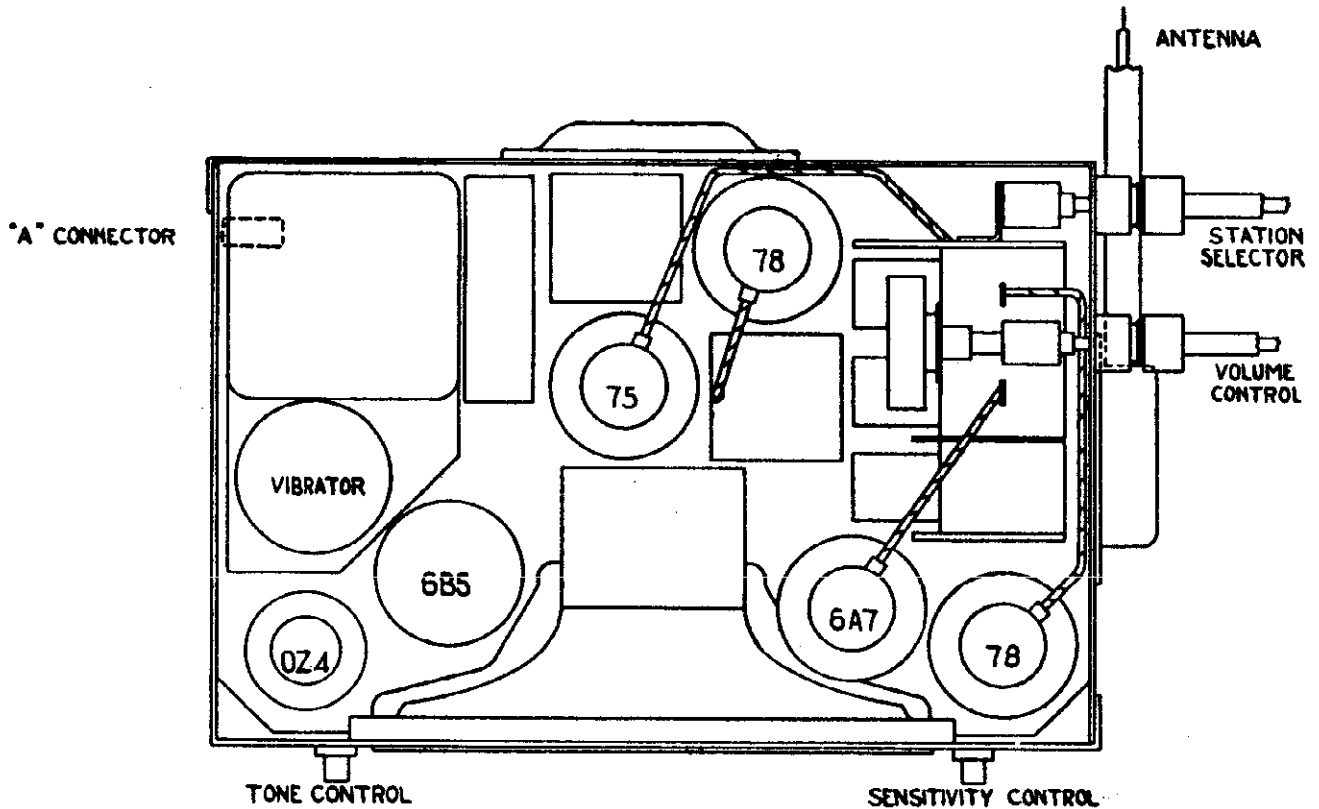

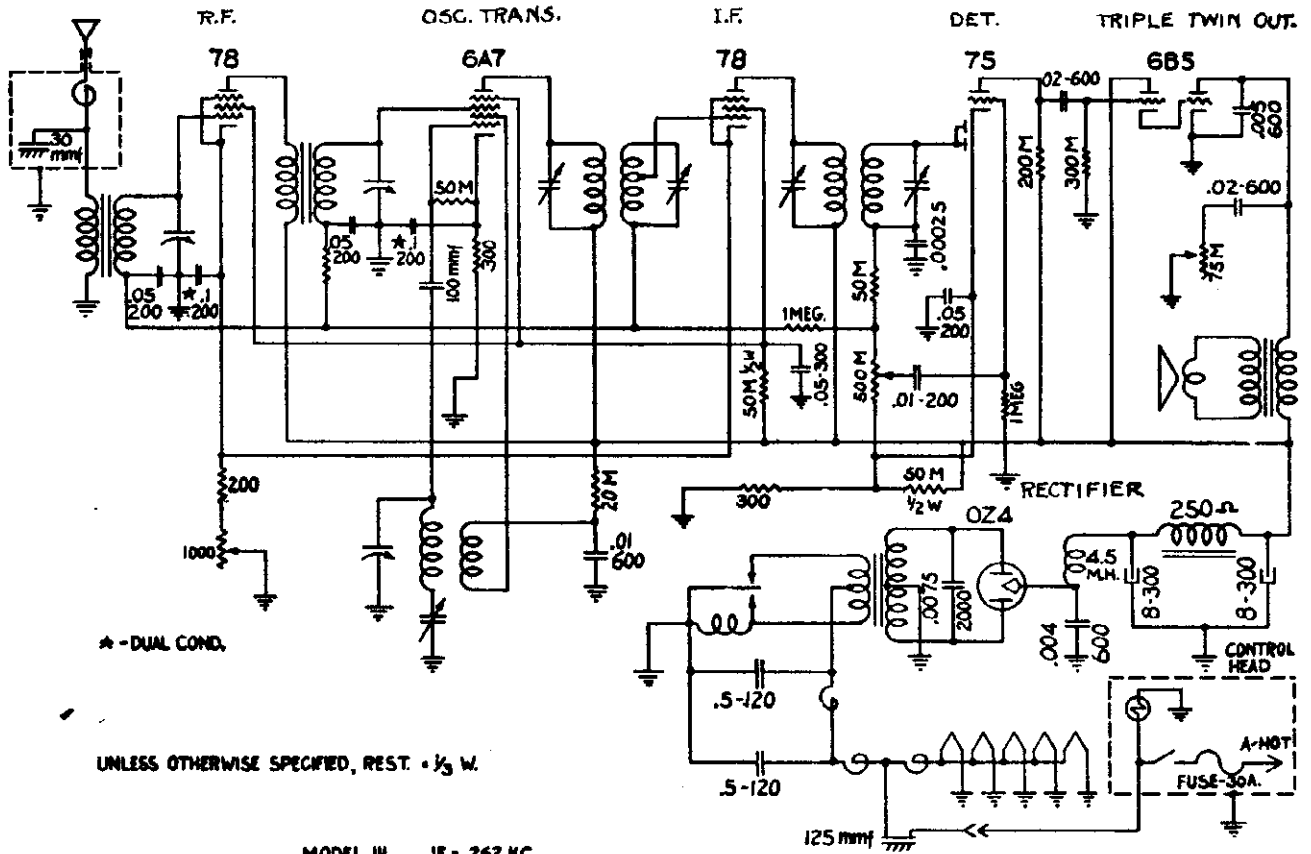

(b) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON). Turn the fidelity control to its middle position and turn the phantom control to the left (NORMAL).

(c) Set the signal generator to 450 kilocycles.

(d) Open the middle trimmer condenser of the 2nd I.F. transformer (Fig. 4) three or four turns of the adjustment screw. (Care should be taken that

DETROLA RADIO CORP.

DETROLA RADIO CORP.

Alignment, Parts

Batteries required for operation of this receiver are:

- 1— 3 Volt dry "A" pack.
- 3—45 Volt Standard "B" batteries.

No "C" batteries are necessary.

DO NOT USE A 6 VOLT BATTERY.

Connect a high impedance AC voltmeter across loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from generator. Strong signals tend to cause improper adjustments.

IF. Connect signal generator ground to receiver ground. Using .1 mfd condenser in series with "high" side of generator, apply 480 KC signal to grid of 1A4 and adjust second IF transformer; same for first IF transformer, applying signal to grid of IC6.

RF. Using 200 mmf condenser in series with generator, feed 1725 KC signal to antenna lead and adjust BC oscillator trimmer (located center under base). Set generator to 1400 KC. Tune receiver and adjust BC antenna trimmer (located on coil on top of base). Set generator to 600 KC. Tune receiver and adjust BC oscillator padder (located between variable and IB1 tube). The tuning condenser should be rocked back and forth through the signal while padder is being adjusted to obtain perfect alignment.

Using 400 ohm resistor in series with generator, set band selector in SW (right) position, and feed 15600 KC signal to antenna lead and adjust SW oscillator trimmer (on coil back of band selector switch); screw trimmer down tight and unscrew to SECOND peak. Set generator to 15000 KC and adjust SW antenna trimmer (on coil back of tuning control); screw trimmer down tight and unscrew to FIRST peak. Rocking tuning control back and forth through signal while adjusting screw. Above procedure for alignment at 15000 KC should be followed exactly to insure proper tracking. A "dead spot" at about 12000 KC will result if oscillator and antenna circuits are not set in proper relation to each other.

R10 300M 1/3 w.
R11 20 ohms. 1/2 w.
R12 100 ohms. 1/3 w.

MODEL 135 same as MODEL 135-E but without tuning eye.

- Tubes required are:
1- 6A7 Oscillator-Translator
1- 6D6 Intermediate Frequency Amplifier
1- 6G5 Detector-Automatic Volume Control
1- 43 First Audio

- C1, C2 .005 - 600 v.
C3 180 mmf. trimmer
C4, C5, C6, C7, 1 - 10 mmf. trimmer
C8 350 mmf. padder
C9 .02 - 600
C10 1150 mmf. mica
C11, C12 .05 - 200
C13, C14, C15, C16 1 - 200 v.

DETROLA RADIO CORP.

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use 1/2 volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

R. F. Alignment

To align the broadcast band, proceed as follows: First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series to the antenna lead of the set. Make sure the band switch of the set is in the broadcast position. Set the

volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1720 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1720 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the first detector trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1720, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

Short Wave Alignment

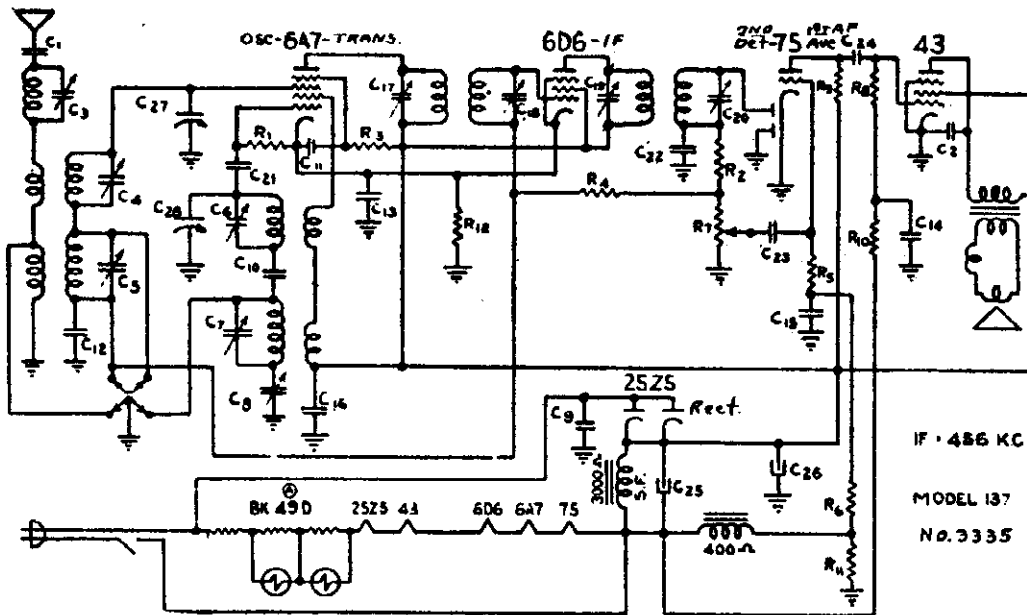

Turn the band selector switch of the set to short wave. Set the signal generator to 6000 K.C. Connect a 400 ohm resistor in series with the .00025 condenser. Tune the set until the signal is heard. If two signals are heard, always align to the highest frequency heard on the receiver. Adjust the small trimmer on the antenna coil for maximum output.

MODELS 136 & 149 are the same except that the 6G5 Tuning Tube is not used.

TUBE LAYOUT and CONNECTION DIAGRAM

ALIGNMENT PROCEDURE

Connect a high impedance AC voltmeter across loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from generator, strong signals tend to cause improper adjustments.

IF. Connect generator ground to receiver ground. Using .1 mfd condenser in series with "high" side of generator, apply 456 kc signal to grid of 6S7G and adjust second IF transformer; same for first IF, applying signal to grid of 6D8G. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using 200 mmf condenser in series with generator, feed 1725 kc signal to antenna lead and adjust oscillator top frequency. Set generator at 1400 kc, tune receiver to signal and adjust broadcast antenna trimmer. Set generator to 600 kc, tune receiver and adjust paddler. The tuning condenser should be rocked back and forth through the signal while the paddler is being adjusted in order to obtain perfect alignment.

Using 400 ohm resistor in series with generator, set band selector in short wave (right) position, feed 15,600 kc signal to antenna and adjust oscillator trimmer—screw trimmer down tight and unscrew to SECOND peak. Set generator to 15,000 kc, tune receiver and adjust antenna trimmer—screw trimmer down tight and unscrew to FIRST peak, rocking the condenser back and forth through the signal while the adjustment is being made. Above procedure for alignment at 15,000 kc must be followed exactly to insure proper tracking. A "dead spot" at about 12,000 kc will result if antenna and oscillator are not set in proper relation to each other.

ALIGNMENT PROCEDURE

Connect a high impedance AC voltmeter across loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from generator, strong signals tend to cause improper adjustments.

IF. Connect generator ground to received ground. Using .1 mfd condenser in series with "high" side of generator, apply 456 kc signal to grid of 6S7G and adjust second IF transformer; same for first IF, applying signal to grid of 6D8G. (See above diagram for location of tubes and transformers.)

RF. (See above diagram for location of trimmers.) Using 200 mmf condenser in series with the generator, feed 1660 kc to antenna lead and adjust broadcast oscillator trimmer for top frequency. Set generator to 1400 kc, tune receiver and adjust the two antenna trimmers. Set generator to 600 kc, tune receiver to signal and adjust padder. The tuning condenser should be rocked back and forth through the signal while the padder is being set in order to secure perfect alignment.

Using 400 ohm resistor in series with generator, set band selector in center position, set generator to 5400 kc and adjust oscillator trimmer for top frequency. Set generator to 5000 kc, tune receiver to signal and adjust antenna trimmer.

Turn band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc—screw trimmer down tight, then unscrew to second peak. Set generator to 15,000 kc, tune receiver to signal and adjust antenna trimmer—Screw trimmer down tight, then unscrew to first peak, rocking the tuning condenser back and forth through the signal while the adjustment is being made. Above procedure for alignment at 15,000 kc must be followed exactly to insure proper tracking. A dead spot at about 12,000 kc will result if antenna and oscillator circuits are not set in proper relation to each other.

I. F. PEAK 456KC
MODEL 147-the same as MODEL 147E -ECR
except that Tuning Tube 6G5

I. F. Alignment
is not used.

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.
 It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use 1/2 volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.
 RF. (See above diagram for location of trimmers.) Using 200 mmf condenser in series with the generator, feed 1660 kc to antenna lead and adjust broadcast oscillator trimmer for top frequency. Set generator to 1400 kc, tune receiver and adjust the two antenna trimmers. Set generator to 600 kc, tune receiver and adjust padder. The tuning condenser should be rocked back and forth through the signal while the padder is being set in order to secure perfect alignment.

Using 400 ohm resistor in series with generator, set band selector in center position, set generator to 5400 kc and adjust oscillator trimmer for top frequency. Set generator to 5000 kc, tune receiver to signal and adjust antenna trimmer.

Turn band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc—screw trimmer down tight, then unscrew to second peak. Notes

DETROLA RADIO CORP.

Tubes required are:

- 1—6A7 Oscillator Translator
- 1—6D6 I. F. Amplifier

- 1—75 Detector A. V. C. Audio Amplifier
- 1—76 Phase Inverter
- 2—43 Output
- 1—25Z5 Rectifier

TUBE LAYOUT

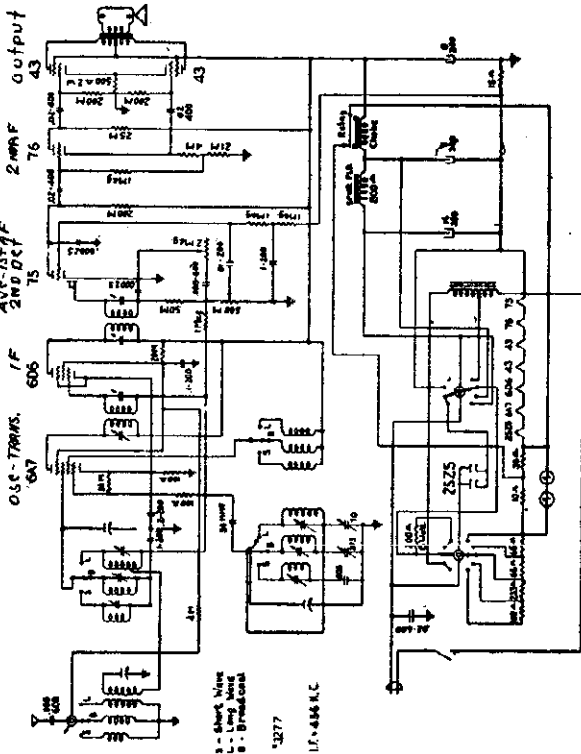

Do not attach a ground to this receiver.

FOR DIRECT CURRENT ONLY

Voltage of Mains	Set Switch B to position marked	Set Switch A to position marked
100 to 120	110	DC 100 to 150
120 to 140	130	DC 100 to 150
140 to 160	150	DC 150 to 250
210 to 230	220	DC 150 to 250
240 to 260	250	DC 150 to 250

FOR ALTERNATING CURRENT ONLY

Voltage of Mains	Set Switch B to position marked	Set Switch A to position marked
100 to 120	110	AC 100 to 130
120 to 130	130	AC 100 to 130
140 to 160	150	AC 130 to 250
210 to 230	220	AC 130 to 250
240 to 260	250	AC 130 to 250

WARNING: READ THESE INSTRUCTIONS BEFORE CONNECTING THIS RECEIVER TO THE ELECTRIC MAINS

This receiver may be adjusted to operate on any current, either direct or alternating of any frequency from 25 cycles to 150 cycles, and at any voltage from 100 volts to 260 volts. The adjustments of the receiver to any voltage or current is accomplished by means of two switches located on the rear panel of the receiver.

Before connecting the receiver to the electric mains, ascertain from your power company the voltage of the mains in your home, and whether it is alternating current or direct current.

When this information has been obtained, the following procedure should be used to set the electrical circuits of the receiver to the line voltage in your home:

Below is a table of main voltage for both direct and alternating currents. Opposite each main voltage in the table, is a designation of the proper setting for each switch. There is a plate on the rear of the chassis that is graduated in the main voltage settings. The switches are adjustable by means of a screw driver. The slot in the switches is also used as an indicator which should point to graduation to be used.

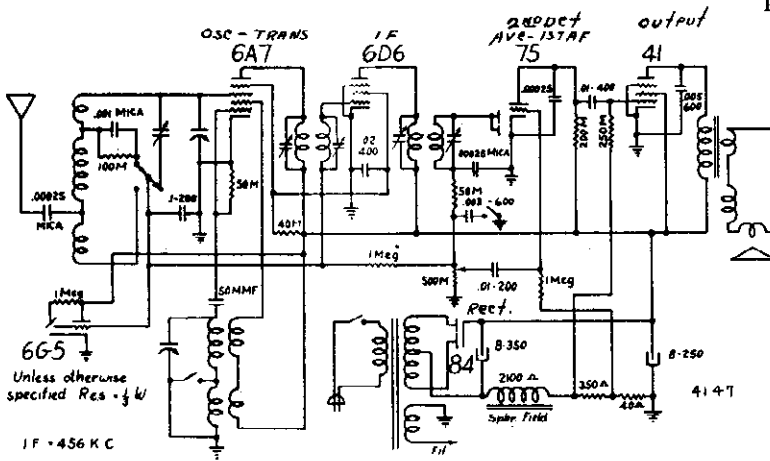

Each switch must be set according to the table. They must not be changed on the set while it is connected to the mains. Unless these instructions are properly carried out serious harm to the electrical parts in the receiver will result.

R. F. Alignment

First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Make sure the band switch of the set is in the broadcast position. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1720 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1720 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the first detector trimmer for maximum output.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

Short Wave Alignment

Turn the band selector switch of the set to short wave. Set the signal generator to 6000 K.C. Connect a 400 ohm resistor in series with the .00025 condenser. Tune the set until the signal is heard. If two signals are heard, always align to the highest frequency heard on the receiver. Adjust the small trimmer on the antenna coil for maximum output.

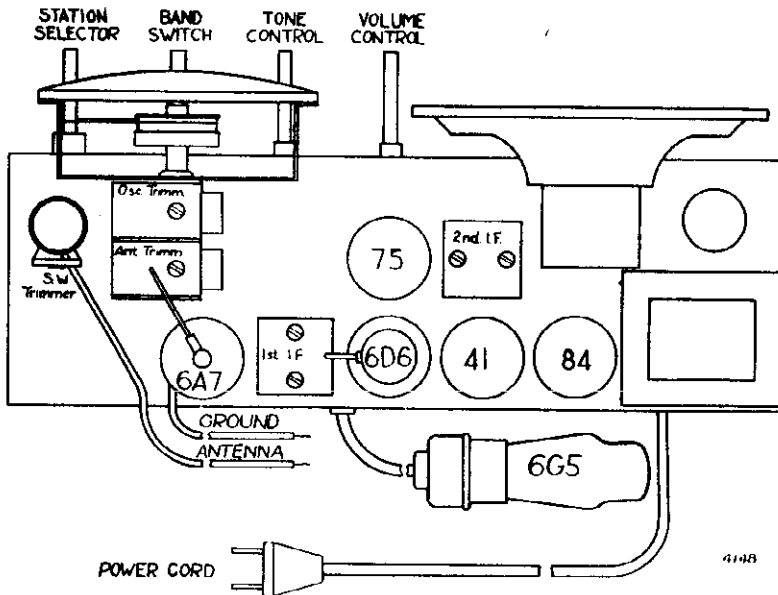

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use $\frac{1}{2}$ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

MODEL 163
Sockets, Trimmer
Alignment

MODEL 155 X

TUBE LAYOUT and CONNECTION DIAGRAM

Connect a high impedance AC voltmeter across the loudspeaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.

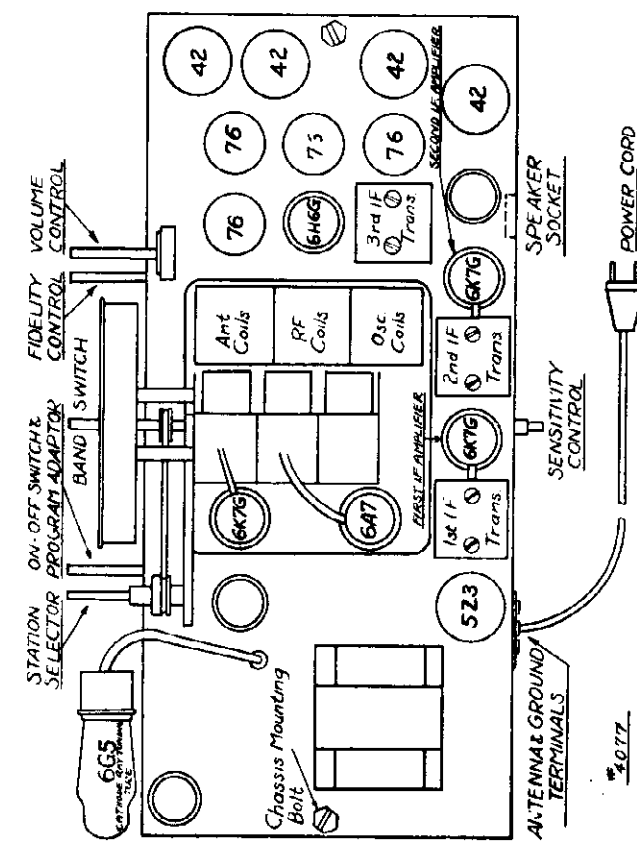

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly align the receiver unless this control is turned part way toward its "bass" position.

IF. Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of the generator, apply 456 kc. signal to the grid of the 6K7 IF amplifier tube and align second IF transformer trimmers. Repeat for first IF transformer, applying signal to grid of the 6A7 tube. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then align the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and align the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrew to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

MODEL 163

Connect a high impedance AC voltmeter across the loudspeaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly align the receiver unless this control is turned part way toward its "bass" position.

IF. Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of generator, apply 456 kc. signal to grid of 6K7G second IF amplifier and align transformer No. 3. Repeat for transformer No. 2, applying signal to grid of 6K7G first IF amplifier. Repeat for transformer No. 1, applying signal to grid of 6A7 transformer. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

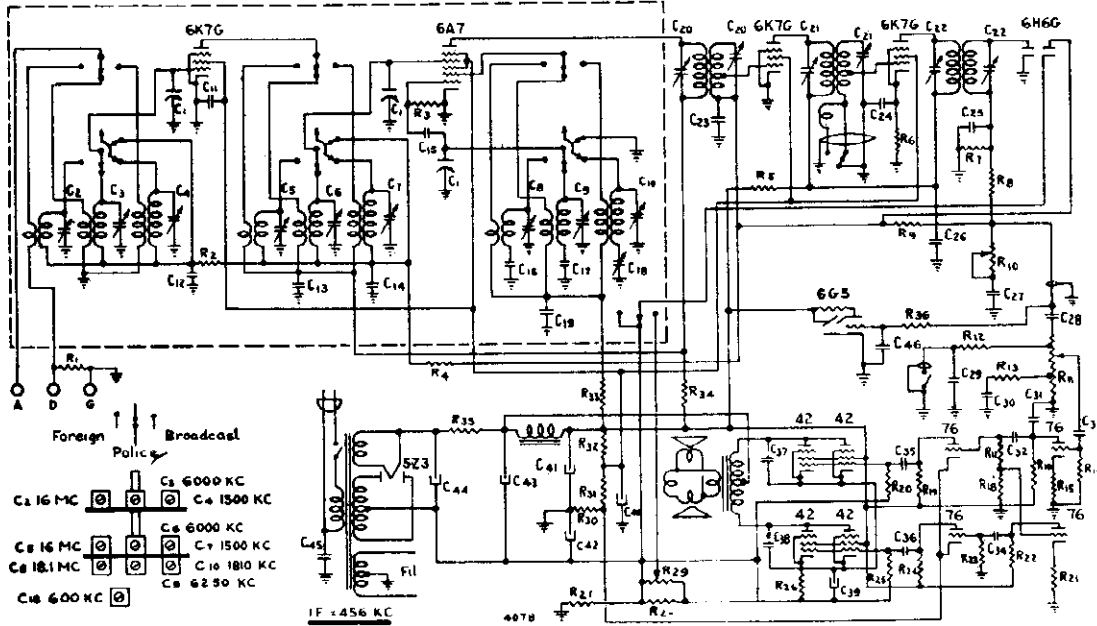

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then align the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and align the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrew to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the volume control is set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use 1/2 volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

R. F. Alignment

To align the broadcast band, proceed as follows:

First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1570 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1570 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the antenna trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1570, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

MODEL 165

Socket

Alignment

DETROLA RADIO CORP.

Tubes must be in proper position and connected as shown.

ALIGNMENT PROCEDURE

Warning! This information is to be used by a *Competent Service Man only* and not by an untrained person.

Connect a high impedance AC voltmeter across the loudspeaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator. Strong signals tend to cause improper adjustments.

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly align the receiver unless this control is turned part way toward its "bass" position.

IF. Connect the generator ground to receiver chassis. Using .1 mfd condenser in series with high side of generator, apply 456 kc signal to grid of 6D6 second IF amplifier and align transformer No. 3. Repeat for transformer No. 2, applying signal to grid of 6D6 first IF amplifier. Repeat for transformer No. 1, applying signal to grid of 6A7 translator. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the padder. The tuning condenser should be rocked back and forth through the signal while varying the padder in order to assure perfect alignment.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then align the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and align the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrewed to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

DETROLA RADIO CORP.

MODEL 167
Schematic, Socket
Trimmers, Alignment, Par

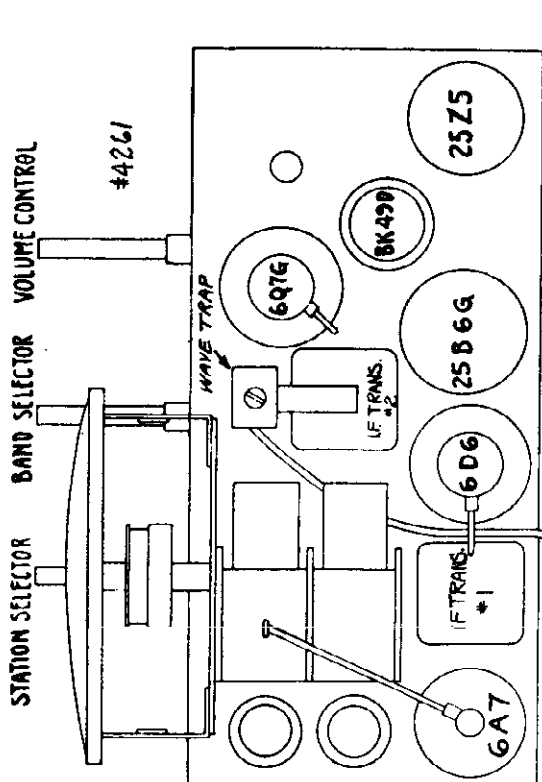

ALIGNMENT PROCEDURE—WARNING! This information is to be used by a COMPETENT SERVICE MAN ONLY and not by an untrained person.
Connect a high impedance A.C. voltmeter across the loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.
I.F.: Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of generator, apply 456 kc. signal to grid of 6D6 I.F. amplifier tube, and align transformer No. 2. Connect generator to grid of 6A7 tube and align transformer No. 1.

SHORT WAVE: A 400 ohm resistor must be used in a series with the generator as a "dummy" antenna for proper alignment of the short wave band. Set the band selector switch in the right hand position; adjust the oscillator top frequency to 6900 kc. then align antenna trimmer at about 6000 kc.

BROADCAST: Using a 100 mmf. condenser in series with the high side of the generator turn band selector switch to left hand position and the tuning condenser to about 600 kc. Feed a 456 kc. signal to the antenna and adjust wave trap trimmer for minimum response. With the tuning condenser at minimum capacity feed 1760 kc. signal to the antenna and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at about 1400 kc. Adjust broadcast antenna trimmer. Set generator for 600 kc., tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

Antenna: This receiver requires very little antenna for proper operation, provided the installation is made correctly. The average length of antenna, including lead-in should be about fifty feet. In locations near powerful broadcast stations, this length should be shortened to thirty-five feet. In more favorable locations, seventy-five feet may be used. Regardless of length, the antenna and lead-in should be spaced well away from the roof, sides of building, trees, power lines, etc. Indoor antennae will give good broadcast reception except in steel frame buildings. However, foreign reception will not be satisfactory unless a good, well insulated, outdoor antenna is used.

NO GROUND IS NECESSARY—UNDER NO CONDITION SHOULD A GROUND WIRE BE ATTACHED TO THIS RECEIVER.

MODEL 169

**Schematic, Socket
Trimmers, Alignment, Parts**

DETROLA RADIO CORP.

ALIGNMENT PROCEDURE

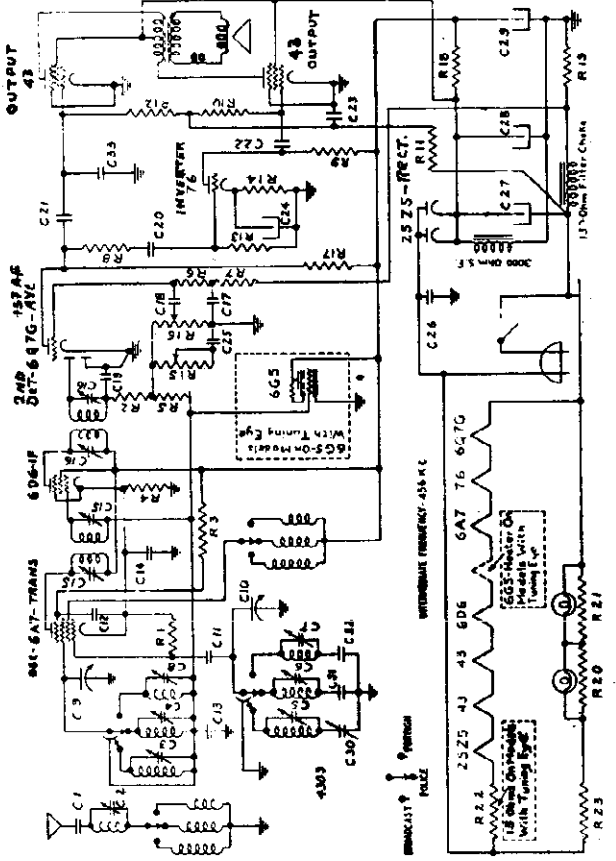

Connect a high impedance AC voltmeter across loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from generator, strong signals tend to cause improper adjustments. I.F.: Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of generator, apply 456 kc. signal to grid of 6D6 I.F. amplifier tube and align transformer No. 2. Connect generator to grid of 6A7 tube and align transformer No. 1.

RF: (See above diagram for location of trimmers.) Using a 200 MMF. condenser in series with the high side of the generator, turn band selector switch to left hand position and the tuning condenser to about 600 kc. Feed a 456 kc. signal to the antenna and adjust wave trap trimmer for minimum response. With the tuning condenser at minimum capacity feed 1660 kc. signal to the antenna and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at about 1400 kc. Adjust broadcast antenna trimmer. Set generator for 600 kc. tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

Using 400 ohm resistor in series with generator, set band selector in center position. Set generator to 5000 kc. tune receiver to signal and adjust antenna trimmer to 5000 kc. Tune band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc.—screw trimmer down tight, then unscrew to second peak. Set generator to 15,000 kc. tune receiver to signal and adjust antenna trimmer.—Screw trimmer down tight, then unscrew to first peak, rocking the tuning condenser back and forth through the signal while the adjustment is being made. Above procedure for alignment at 15,000 kc must be followed exactly to insure proper tracking. A dead spot at about 12,000 kc will result if antenna and oscillator circuits are not set in proper relation to each other.

Tubes must be in proper position and connected as shown.

SERVICE NOTES

MODEL 200 ELECTROCALL

Failure to Function:

- A. Defective tube (loose screen grid Cap.)
- B. Open resistor line cord.
- C. Defective filter condenser:-

If unit does not operate and voltages check O.K., suggest adding 8 mfd. 200 V condenser in parallel with filter in unit. If unit operates, replace filter condenser.

- D. Defective "Talk-Listen" switch:-

Remove set from cabinet - loosen set screws and remove lever arm - open retainer washer on shaft - remove rotor of switch - clean contacts with Carbona - bend rotor arms to increase tension - assemble switch making certain lever arm is in original position.

- E. Open 1700 ohm resistor or discolored:

Replace both resistor and seven prong tube (seven prong tube has developed internal short).

- F. Reverse Line plug if connected to Direct Current.

Failure of Pilot Light:

- A. Pilot lamp burned out or making poor contact.
- B. Defective tube or open line cord.
- C. Pilot lamp socket opened, shorted, or grounded.
- D. Open 25 ohm wire wound resistor.

Excess Hum:

- A. Defective 6 prong tube.
- B. Defective Filter Condenser:-

To check -- connect 8 mfd. 200 volt condenser in parallel with filter in unit. If hum ceases, replace filter condenser.

Weak Response:

- A. Check second section of filter cond.
- B. Check speaker adjustment.
- C. Check tubes.

Speaker Rattles or Poor Quality:

This may be remedied by adjusting screw as indicated, also check for loose pilot lamp or bracket.

ADJUST THIS SCREW ONLY (NEAREST MAGNET)

If Unit "A" rattles when speaking into Unit "B" - recheck adjustments on both speakers as it may be either the microphone unit or speaker.

If voice is audible through "A" when speaking into "B" but not vice-versa, then "A's" unit is defective.

If units howl or squeal due to close proximity, insert 10,000 ohm resistor in series with one side of the cable, as illustrated.

Voltages - taken with 1000 ohm per Volt meter:

- Across 1700 ohm resistor 12 to 16 Volts
- Across 3500 ohm resistor 1/2 to 1 Volt
- Across B plus to B minus 125 to 150 Volts.

DO NOT SHORTEN LINE CORD UNDER ANY CONDITIONS.

Connect conventional extension cord, should it be necessary to extend length of line cord furnished with units.

DEWALD RADIO

GENERAL INSTRUCTIONS

202-M MASTER UNIT

TO TALK:

This device is of a multiple system type, designed to operate on 25-60 cycles A.C. or D.C. 110-120 volts.

The master station may select and hold two way conversation with any one remote station and yet may not be overheard by any other station. Any remote station may also call the master and not be overheard by other stations.

INSTALLATION:

After locating the units the cables should be run in the most convenient manner. These cables carry no power, but care should be taken that they do not come in contact with electrical or telephone lines. It is also advisable not to run them parallel. (If they have to be run parallel, keep them as far apart as possible.)

TO OPERATE:

Snap middle switch to "ON" position and wait from ten to twenty seconds for tubes to heat. When operating instrument from direct supply line, it may be necessary to reverse the current plug at the calling stations if instrument at other end of line fails to respond and vice versa.

CALLING SIGNAL:

Turn Station Selector Switch to station desired, press "Call Listen" lever down and pull out.

Press "Talk-Listen" switch down. This switch must be held down all the while when talking. Each instrument is normally in a position to receive calls regardless of whether the switch is turned on or off. It is only necessary to turn on the instrument when calling.

TO RECEIVE CALLS:

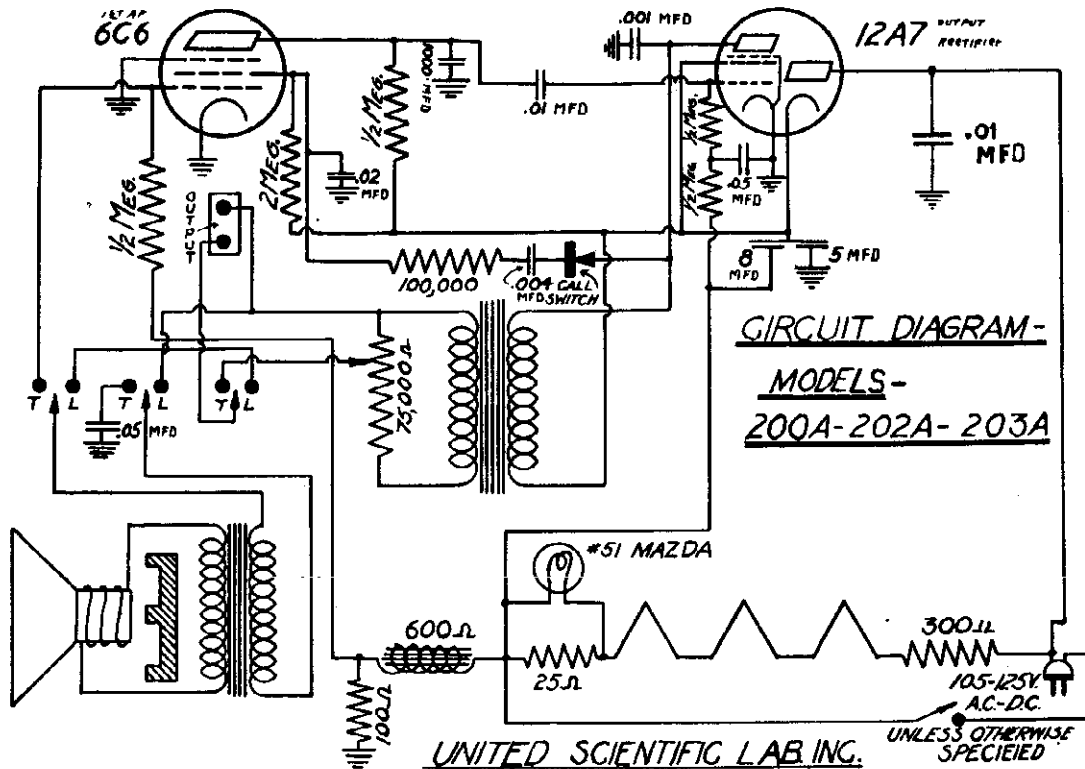

To signal master station from individual outlying station, most convenient practice is to adapt a call system corresponding with the numerals on the master terminal board. That is, if the outlying station is attached to #5 on terminal board, then this station should depress the "Talk-Listen" key five times, when desiring to converse through the master unit.

It is advisable to set station selector switch to a neutral position, which is indicated by the small arrow head between station numerals, when master instrument is not in use.

When operating Electrocall, the user should talk about an arm's length away from the grill and in an ordinary conversational tone. Talking loudly into the grill will result in greater amplification at the receiving end.

Both units must be turned "ON" when holding two way conversation. When continuous service is desired, it is necessary to keep all units turned "ON"

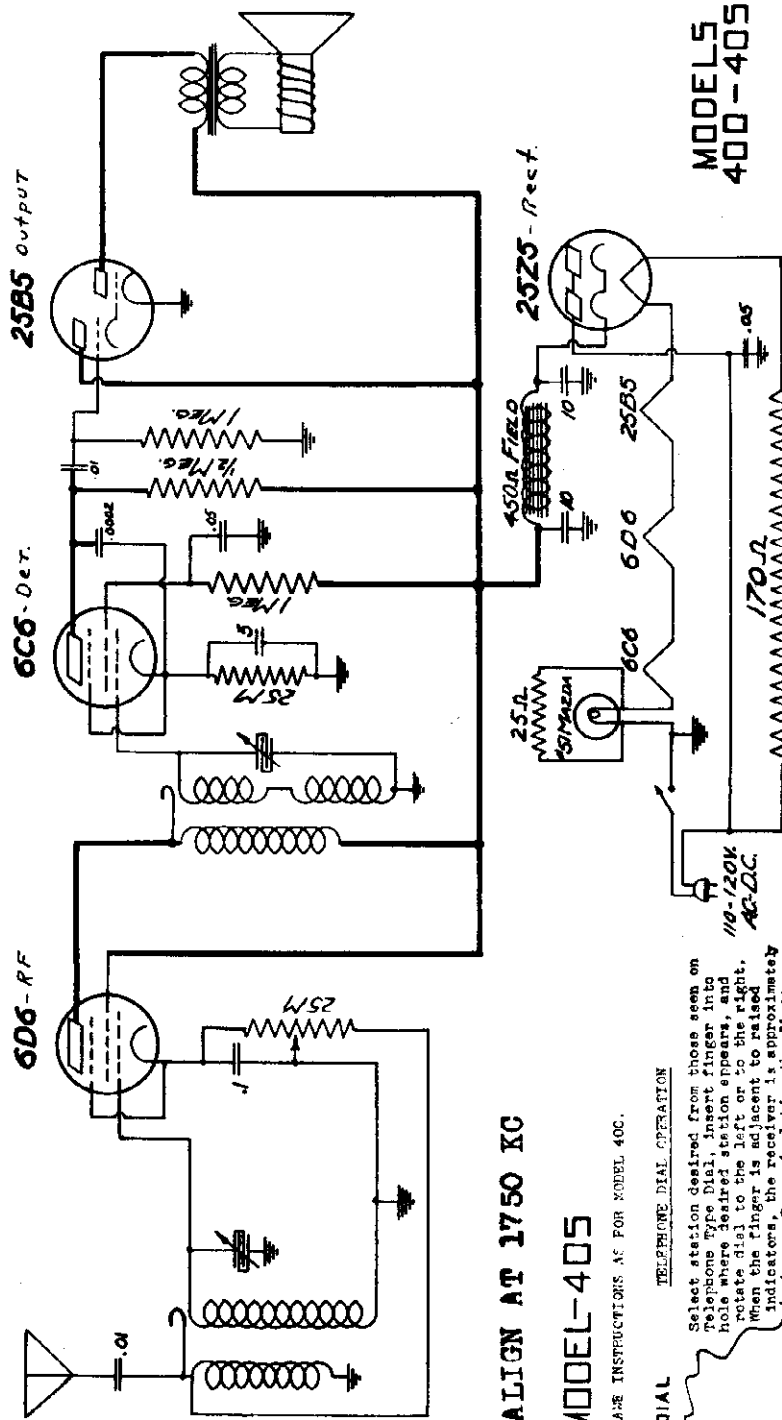

The tubes used for the Electrocall are especially designed for this system and can only be obtained directly from the manufacturer or through any Electrocall distributor. These tubes carry our regular ninety day guarantee.

ALIGN AT 1750 KC

MODEL-405

FOLLOW THE SAME INSTRUCTIONS AS FOR MODEL 400.

TELEPHONE DIAL

TELEPHONE DIAL OPERATION

Select station desired from those seen on Telephone Type Dial. Insert finger into hole where desired station appears, and rotate dial to the left or to the right. When the finger is adjacent to raised indicators, the receiver is approximately in tune. By manipulating the finger within the range of indicator, station may be tuned perfectly.

Some stations must be tuned by turning the dial plate clockwise, and some counter-clockwise. The station name should always appear upright when brought to raised indicators. By this, one can tell which direction the dial should be turned to tune in a station.

NOTE: If one prefers to use the knob the kilocycle scale on top is used.

This receiver is a 4 tube T.R.F. and designed to operate on 110-120 Volts - 60-80 cycles, alternating current or direct current unless otherwise specified on rear of chassis.

RANGE: The tuning range of this receiver is from 540 to 1750 Kilocycles. This range covers all of the standard American broadcast stations and some Police Calls.

ANTENNA: Unwind reel of brown wire and place same along the base-board. In shielded buildings, it is advisable to hang the wire out of the window or connect it to an outside antenna. No ground is necessary with this receiver.

TUBES: 1-606, 1-606, 1-25B5, 1-25B5.

CONTROLS: The upper control is the station selector knob. The lower one is the On-Off Switch and the volume control.

IMPORTANT: DO NOT CONNECT A GROUND WIRE TO THE CHASSIS. DO NOT CHANGE THE LENGTH OF THE LINE COIL.

DEWALD RADIO

FOR SERVICING TO CALIBRATE:
Set service oscillator to 456 K.C. and connect "EO" lead to grid of 1A6 tube and connect stator of rear (oscillator) section of variable condenser. Turn volume control for maximum output and peak intermediate frequency trimmers for maximum gain.
Remove short from variable condenser. Remove service oscillator lead from grid of 1A6 tube and connect same to red lead on rear of set. Adjust service oscillator and the receiver to 1500 K.C. and peak trimmers on variable condenser for maximum gain. All the other frequencies are automatically calibrated when receiver is peaked at 1500 K.C. due to the construction of the cut section of variable condenser.

BATTERY SUPPLY: This receiver is designed to operate from a 2-volt storage battery, 2.5 volt "air cell" battery, 3-volt "A" pack or a 6-volt storage battery.

IMPORTANT:
1. Before operating this receiver, make certain that the spade lug which is attached to the yellow lead extending through rear of chassis is fastened to the proper terminal on the battery terminal strip. See Sketch.
2. See circuit drawing for battery connections.
3. Be certain all battery wires and plugs are properly connected.

4. Push mounting bracket through the mounting nut.
5. Push mounting bracket through the mounting stud.
6. Push mounting bracket through the mounting washer.
7. Install distributor suppressor in Distributor.

MODEL 527

CALIBRATION INSTRUCTIONS:

Connect test coil, "hot lead" to the grid of the 6A7 tube, and the "cold" lead to the receiver chassis. Short the antenna terminals to the chassis. Turn the antenna switch to I.F. two trimmers on the top of the aluminum slide and trimmer in rear of speaker to 456 K.C. After the trimmer has been set, remove short from the variable condenser and connect the antenna to the receiver. Set oscillator and Receiver Load-in of the Receiver. Set test oscillator and Receiver to 1600 K.C. and adjust variable condenser trimmer for maximum signal.

1. Assemble mounting brackets to spring clip at end of wire. Use the self-tapping screw provided, compress the clip and install on battery side of antenna.
2. Connect antenna lead on right side of set to ear antenna.
3. Assemble mounting brackets to receiver.
4. Determine location of receiver as in Figure I. Spot and drill two 1/8" holes in the lower section of the dash-board to correspond with the two holes in the mounting brackets.
5. Drill a 3/8" hole in fire board to line up with tapped hole in rear of receiver. (See Figure II)

In Model 528 L.W.,
 L1, C1, L2 & C2 are in circuit.
 In Model 528
 L1, L2, C1, & C2 are omitted.

Connect external Oscillator's hot lead to reel antenna of receiver.
 Connect oscillator cold lead in series with a 4 or .1 μ F condenser
 to receiver chassis. Set oscillator at 1800KC and peak Variable Con-
 denser trimmers for Maximum signal with condenser set approximately
 where 1500 comes in on scale.

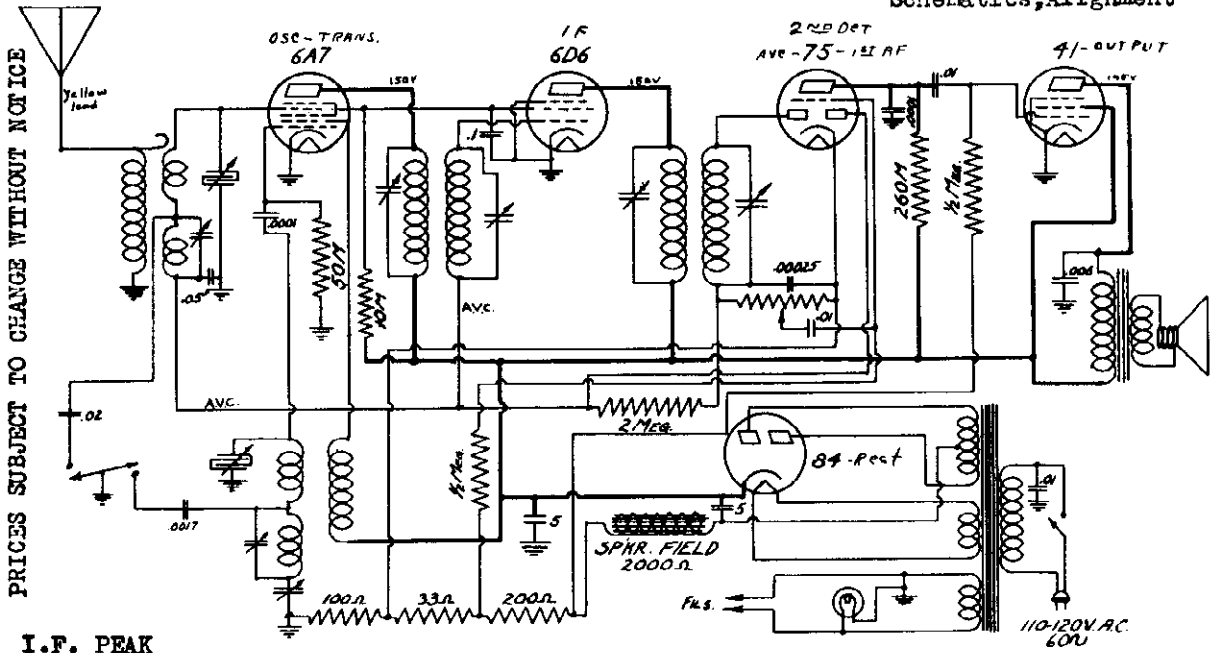

MODEL 1200

TO CALIBRATE:
 Set service oscillator to 456 K.C. and connect "HOT"
 lead to grid of 6A7 tube. Ground stator of front
 (oscillator) section of variable condenser. Turn vol-
 ume control for maximum output and peak intermediate
 frequency trimmers for maximum gain. Turn wave band
 switch knob toward right. Adjust service oscillator
 and receiver to 7 megacycles and peak variable con-
 denser trimmers for maximum gain. Turn wave band
 switch toward left and adjust oscillator (service)
 and receiver to 1500 K.C. Peak both trimmers under-
 neath chassis for maximum gain. Then adjust service
 oscillator and receiver to 600 K.C. and "peak" the variable
 condenser and adjust the padder (near front of chassis
 on top) at the same time for maximum gain.

Turn volume control for maximum output and peak intermediate frequency trimmers for maximum gain. Turn wave band switch knob toward left. Adjust service oscillator and receiver to 7 megacycles and peak variable condenser trimmers for maximum gain. Turn wave band switch toward right and adjust service oscillator and receiver to 1500 K.C. Peak the trimmer next to the variable condenser and the one underneath chassis for maximum gain. Then adjust service oscillator and receiver to 600 K.C. and "rock" the variable condenser and adjust the padder (near front of chassis) at the same time for maximum gain.

I.F. PEAK 456 KC.

2376 Comb. electrolytic	1.00	9818 Shaft	.10
7222 Speaker	4.00	9799 Drum	.05

These receivers are dual wave superheterodynes with the automatic volume control features. The frequency ranges are as follows:
Models 629 and 703 - 1650-550 K.C. and 7-2.4 M.C.
Models 629-LW and 703-LW - 1650-550 K.C. and 340-150 K.C.

TO CALIBRATE:

Set service oscillator to 456 K.C. and connect "HOT" lead to grid of 6A7 tube. Ground stator of front (oscillator) section of variable condenser. Turn volume control for maximum output and peak intermediate frequency trimmers for maximum gain. Turn wave band switch knob toward left. Adjust service oscillator and receiver to 7 megacycles and peak variable condenser trimmers for maximum gain. Turn wave band switch toward right and adjust oscillator (service) and receiver to 1500 K.C. Peak both trimmers underneath chassis for maximum gain. Then adjust service oscillator and receiver to 600 K.C. and "rock" the variable condenser and adjust the padder (near front of chassis) at the same time for maximum gain.

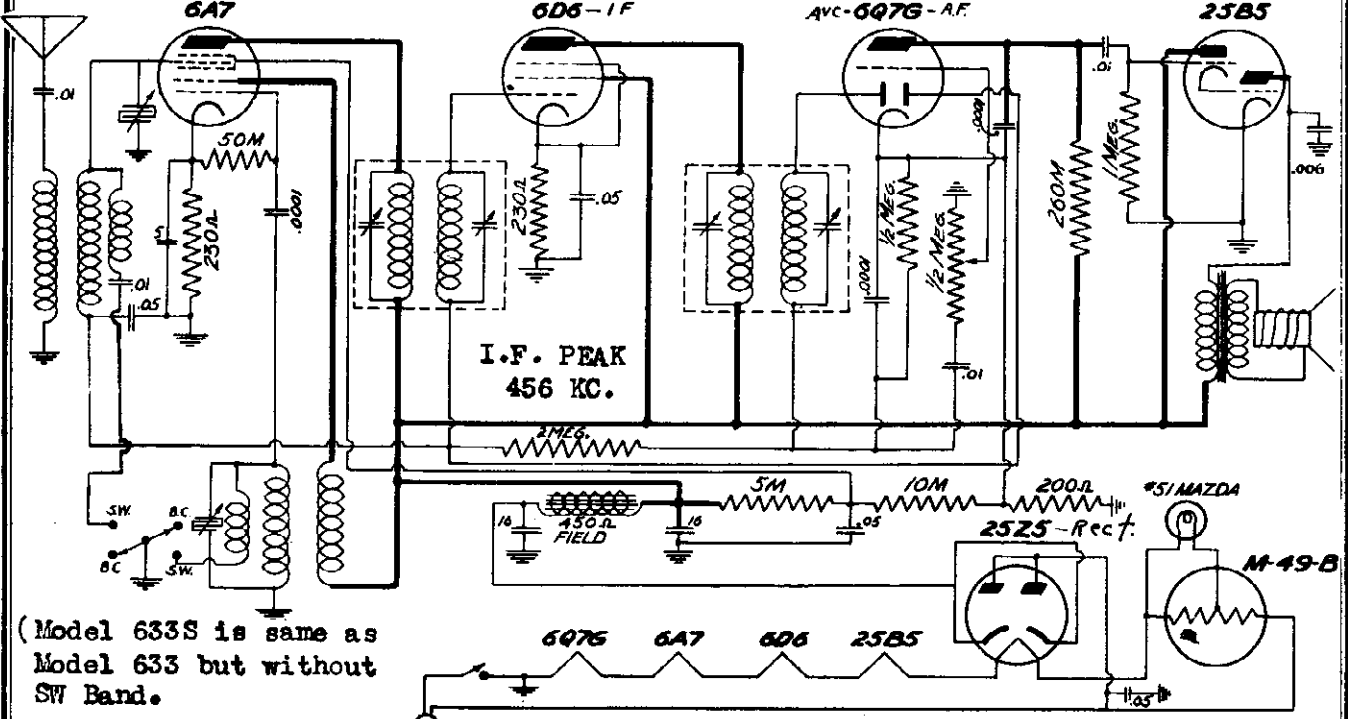

Models 629 and 629-LW: 1-6A7, 1-6D6, 1-75, 1-25L6, 1-25Z5, and 1-M-42-B.
Models 703 and 703-LW: 1-6A7, 1-6D6, 1-75, 1-25L6, 1-25Z5, 1-M-42-B, and 1-605

MODEL 633, 633LW, 633S 2ND DET
 6D6-1F AVC-6Q7G-AF

OUTPUT
 25B5

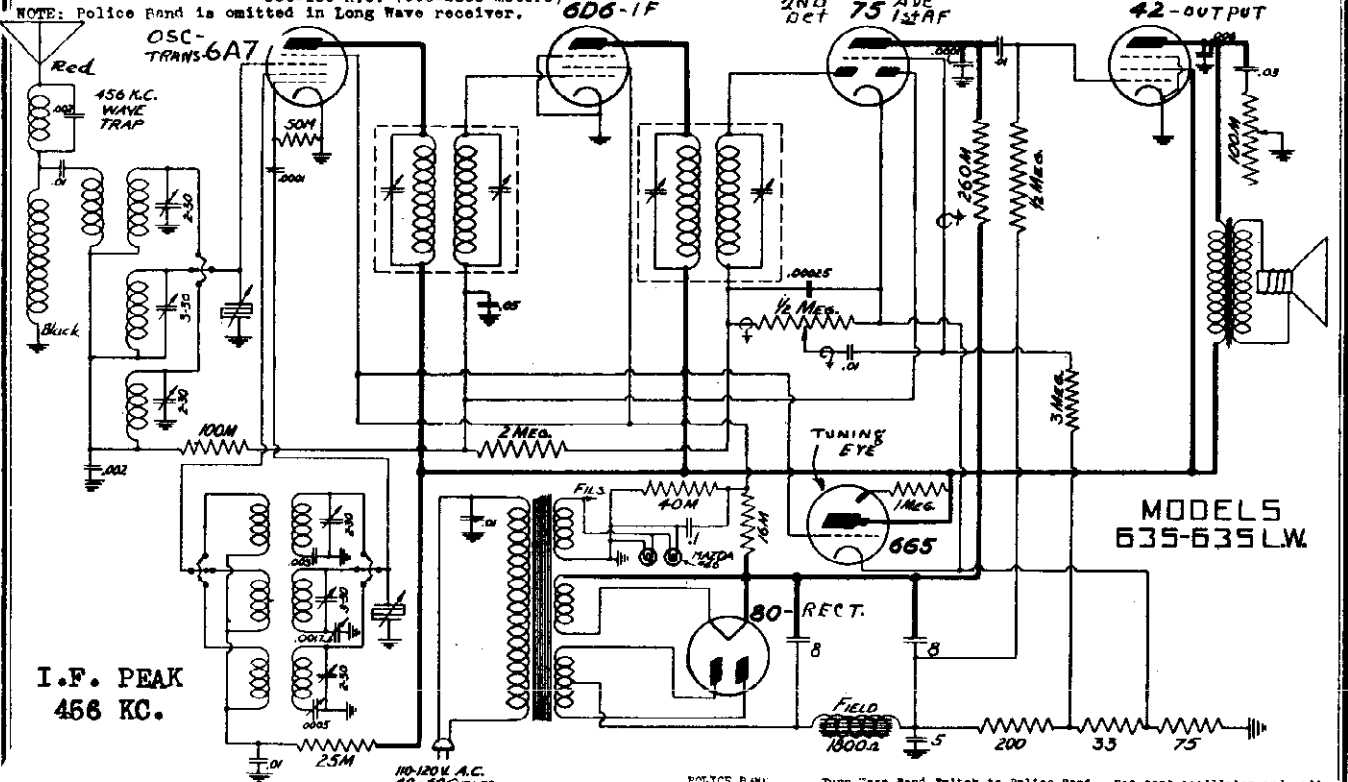

(Model 633S is same as Model 633 but without SW Band.)

The Model 635 has the following ranges:
 550-1700 K.C. (550-175 meters)
 1700-4800 K.C. (175-62 meters)
 5.7-16 M.C. (18-52 meters)

The Model 635LW has the following additional range:
 330-150 K.C. (900-2000 meters)

NOTE: Police Band is omitted in Long Wave receiver.

TO CALIBRATE: Set Service Oscillator to 456 K.C. and connect "HOT" lead to grid of 6A7, Ground stator of rear (oscillator) section of variable condenser. Turn Volume Control for maximum output and peak intermediate frequency trimmer for maximum gain. Remove Variable Condenser short. Adjust service oscillator and receiver to 1500 K.C. and peak variable condenser trimmers for maximum gain.

I.F. PEAK
 456 KC.

MODELS
 635-635LW

I. F. ALIGNMENT: Intermediate frequency peaked at 456 K.C. Connect test oscillator and grid of 6A7 and chassis. Short circuit stator of front section of variable condenser during this operation. Then peak I.F. trimmers for maximum signal.

V. V. ALIGNMENT: Remove short from stator of variable condenser. Turn Wave Band Switch to Broadcast. Connect test oscillator to antenna and chassis. Set test oscillator and radio dial to 1500 K.C. and peak two trimmers underneath chassis, (toward rear) for maximum signal. Set test oscillator at 800 K.C. and adjust ladder condenser (nut side) in front of chassis for maximum signal. During this operation, the variable condenser must be rocked. Readjust 1500 K.C.

POLYCS PANEL ALIGNMENT:

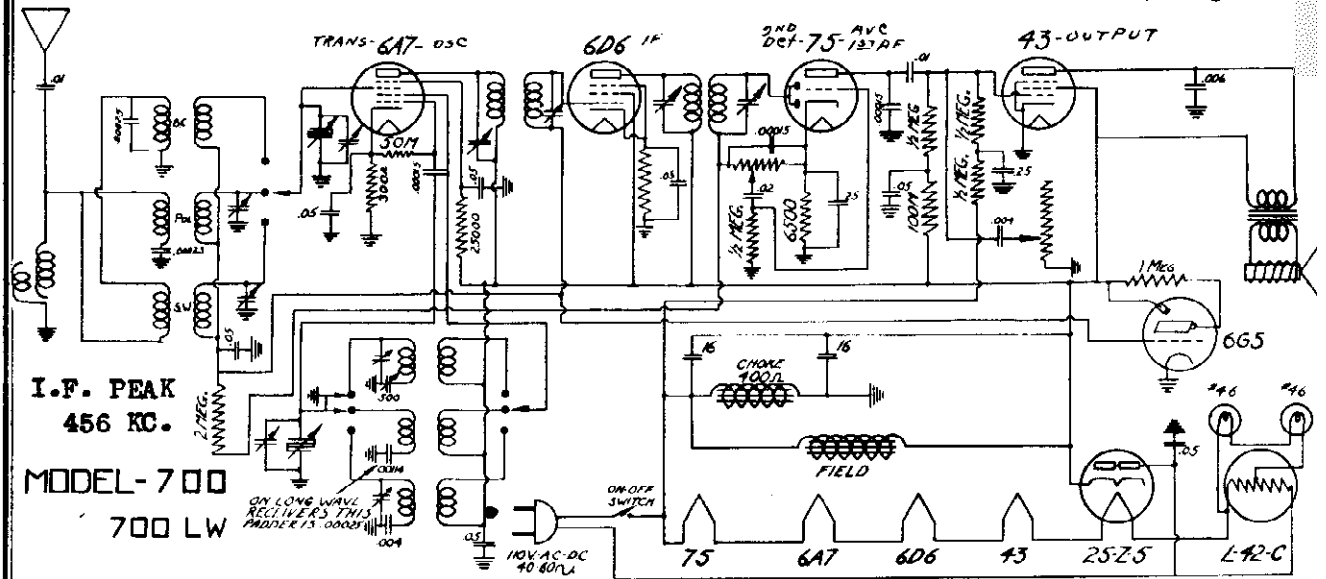

Turn "Wave Band Switch" to Police Band. Set test oscillator and radio dial to 4000 K.C. and peak two trimmers on coil on top of chassis. Set test oscillator and radio to 1700 K.C. and adjust pecker (screw side) for maximum signal. The variable condenser must be rocked during the operation. If receiver has long wave instead of police band, calibrate same trimming condenser as on Police Band, but set oscillator and receiver at 500 K.C. for alignment.

SHORT WAVE ALIGNMENT:

Turn Wave band switch to short wave. Set test oscillator and radio dial to 10 Megacycles and peak trimmers on bottom of chassis (toward front) for maximum signal. Low frequency setting is automatically taken care of by short wave coils which are carefully matched for this setting by a fixed calibrated capacitor.

DEWALD RADIO

MODELS 700, 700LW
MODELS 700A, 700A-LW
Schematics, Alignment

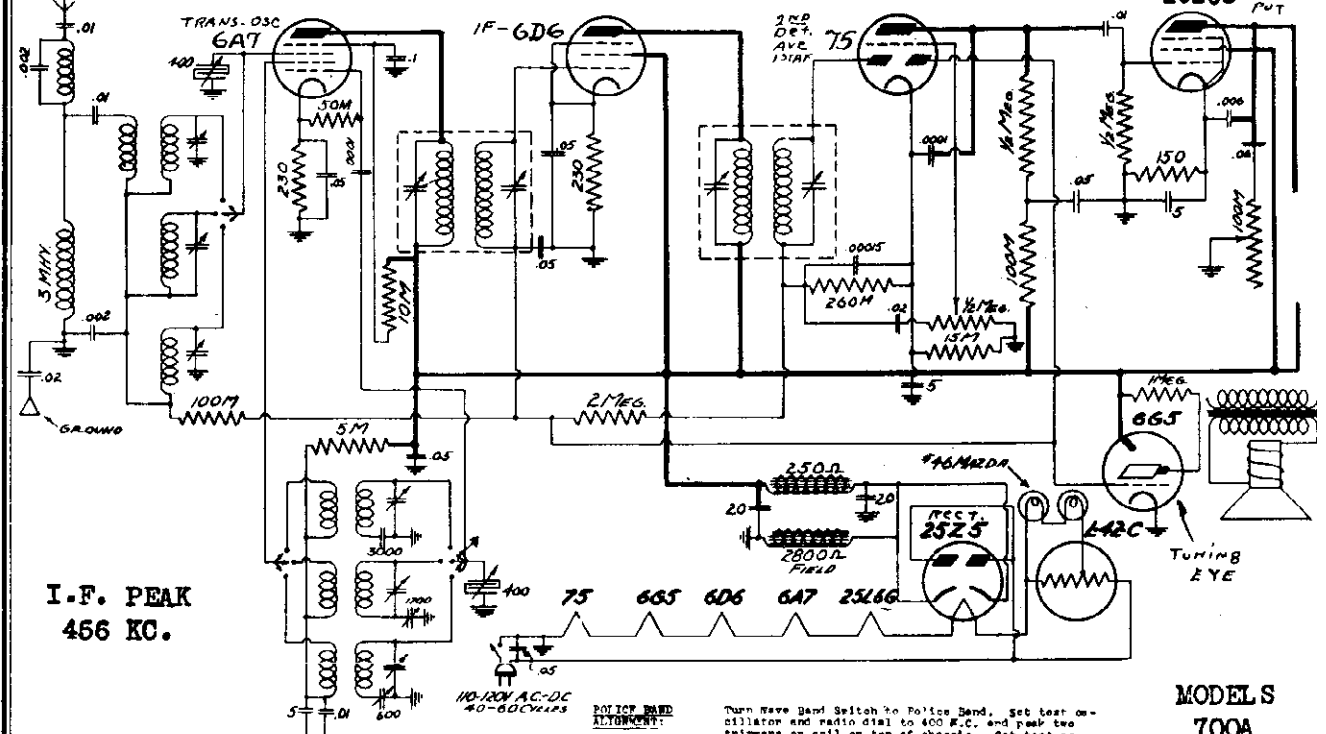

I.F. ALIGNMENT - INTERMEDIATE FREQUENCY PEAKED AT 456 KC. CONNECT TEST OSCILLATOR TO GRID OF 6A7 AND CHASSIS SHORT CIRCUIT STATOR OF FRONT SECTION OF VARIABLE CONDENSER DURING THIS OPERATION. THEN PEAK I.F. TRIMMER FOR MAXIMUM SIGNAL.

B.F. ALIGNMENT - REMOVE SHORT FROM STATOR OF VARIABLE CONDENSER. TURN WAVE BAND SWITCH TO BROADCAST. CONNECT TEST OSCILLATOR TO ANTENNA AND CHASSIS. SET TEST OSCILLATOR AND RADIO DIAL TO 1500 KC. AND PEAK VAR. COND. TRIMMERS FOR MAXIMUM SIGNAL. SET TEST OSC. AT 600 KC. AND ADJUST PADDER CONDENSER IN FRONT OF CHASSIS FOR MAX. SIG. DURING THIS OPERATION THE VAR. COND. MUST BE KEPT READING 1500 KC.

POLICE BAND ALIGNMENT - TURN WAVE BAND SWITCH TO POLICE BAND. SET TEST OSC. AND RADIO DIAL TO 400 KC. AND PEAK 2 TRIMMERS NEAR FRONT OF CHASSIS FOR MAX. SIG. THIS LOW FREQ. SETTING IS AUTOMATICALLY ADJUSTED BY A FIXED CALIBRATED PADDER. IF RECEIVER HAS LONG WAVES INSTEAD OF POLICE BAND CALIBRATE SAME TRIMMING COND. AS ON POLICE BAND BUT SET OSCILLATOR AND RECEIVER AT 300 KC. FOR ALIGNMENT.

SHORT WAVE ALIGNMENT - TURN W.B. SWITCH TO SHORT WAVE. SET TEST OSC. AND RADIO DIAL TO 15M. HERTZES AND PEAK TRIMMERS NEAR CENTER OF CHASSIS FOR MAX. SIG. LOW FREQ. SETTING IS AUTOMATICALLY TAKEN CARE OF BY SHORT WAVE COILS WHICH ARE CAREFULLY MATCHED FOR THIS SETTING BY A FIXED CALIBRATED PADDER.

I. F. ALIGNMENT - Intermediate frequency peaked at 456 K. C. Connect test oscillator to grid of 6A7 and chassis. Short circuit stator of front section of variable condenser during this operation. Then peak I.F. trimmer for maximum signal.

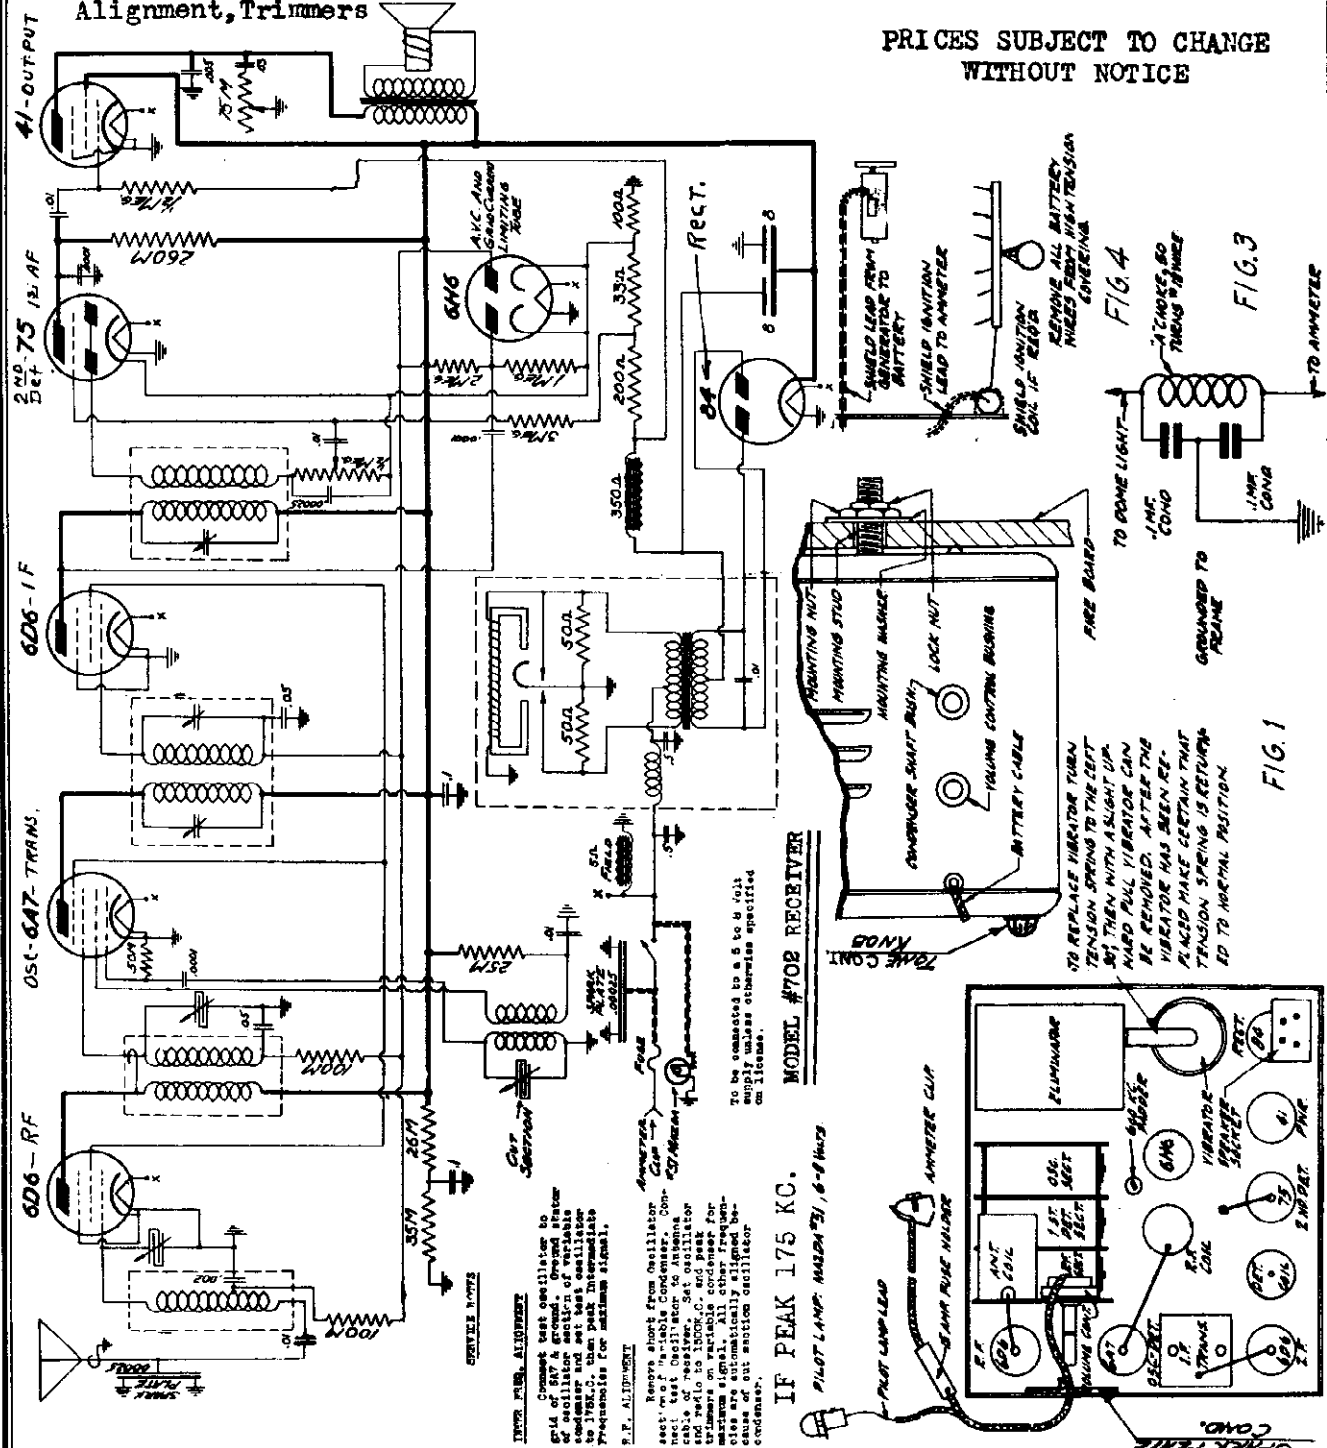

B. F. ALIGNMENT - Remove short from stator of variable condenser. Turn Wave Band Switch to Broadcast. Connect test oscillator to antenna and chassis. Set test oscillator and radio dial to 1500 K.C. and peak two trimmers underneath chassis, (toward rear) for maximum signal. Set test oscillator at 600 K.C. and adjust padder condenser (nut side) in front of chassis for maximum signal. During this operation, the variable condenser must be rocked. Read just 1500 K. C.

POLICE BAND ALIGNMENT - Turn Wave Band Switch to Police Band. Set test oscillator and radio dial to 400 K.C. and peak two trimmers on coil on top of chassis. Set test oscillator and radio to 1700 K.C. and adjust padder (screw side) for maximum signal. The variable condenser must be rocked during the operation. If receiver has long waves instead of police band, calibrate same trimming condenser as on Police Band, but set oscillator and receiver at 300 K.C. for alignment.

SHORT WAVE ALIGNMENT - Turn Wave Band switch to short wave. Set test oscillator and radio dial to 15 MegaCycles and peak trimmers on bottom of chassis (toward front) for maximum signal. Low frequency setting is automatically taken care of by short wave coils which are carefully matched for this setting by a fixed calibrated padder.

Socket, Trimmers
 Alignment

This receiver is equipped with an automatic overload control which necessitates setting the manual volume control of the receiver to its maximum position to insure accuracy in alignment. To control the signal output of the receiver it will be necessary to use the attenuator control of the signal generator. Connect the low potential side of the signal generator to the metal chassis through a .1 mfd. (400 volt) condenser for the following adjustments.

ADJUSTMENT OF I.F. CONDENSERS

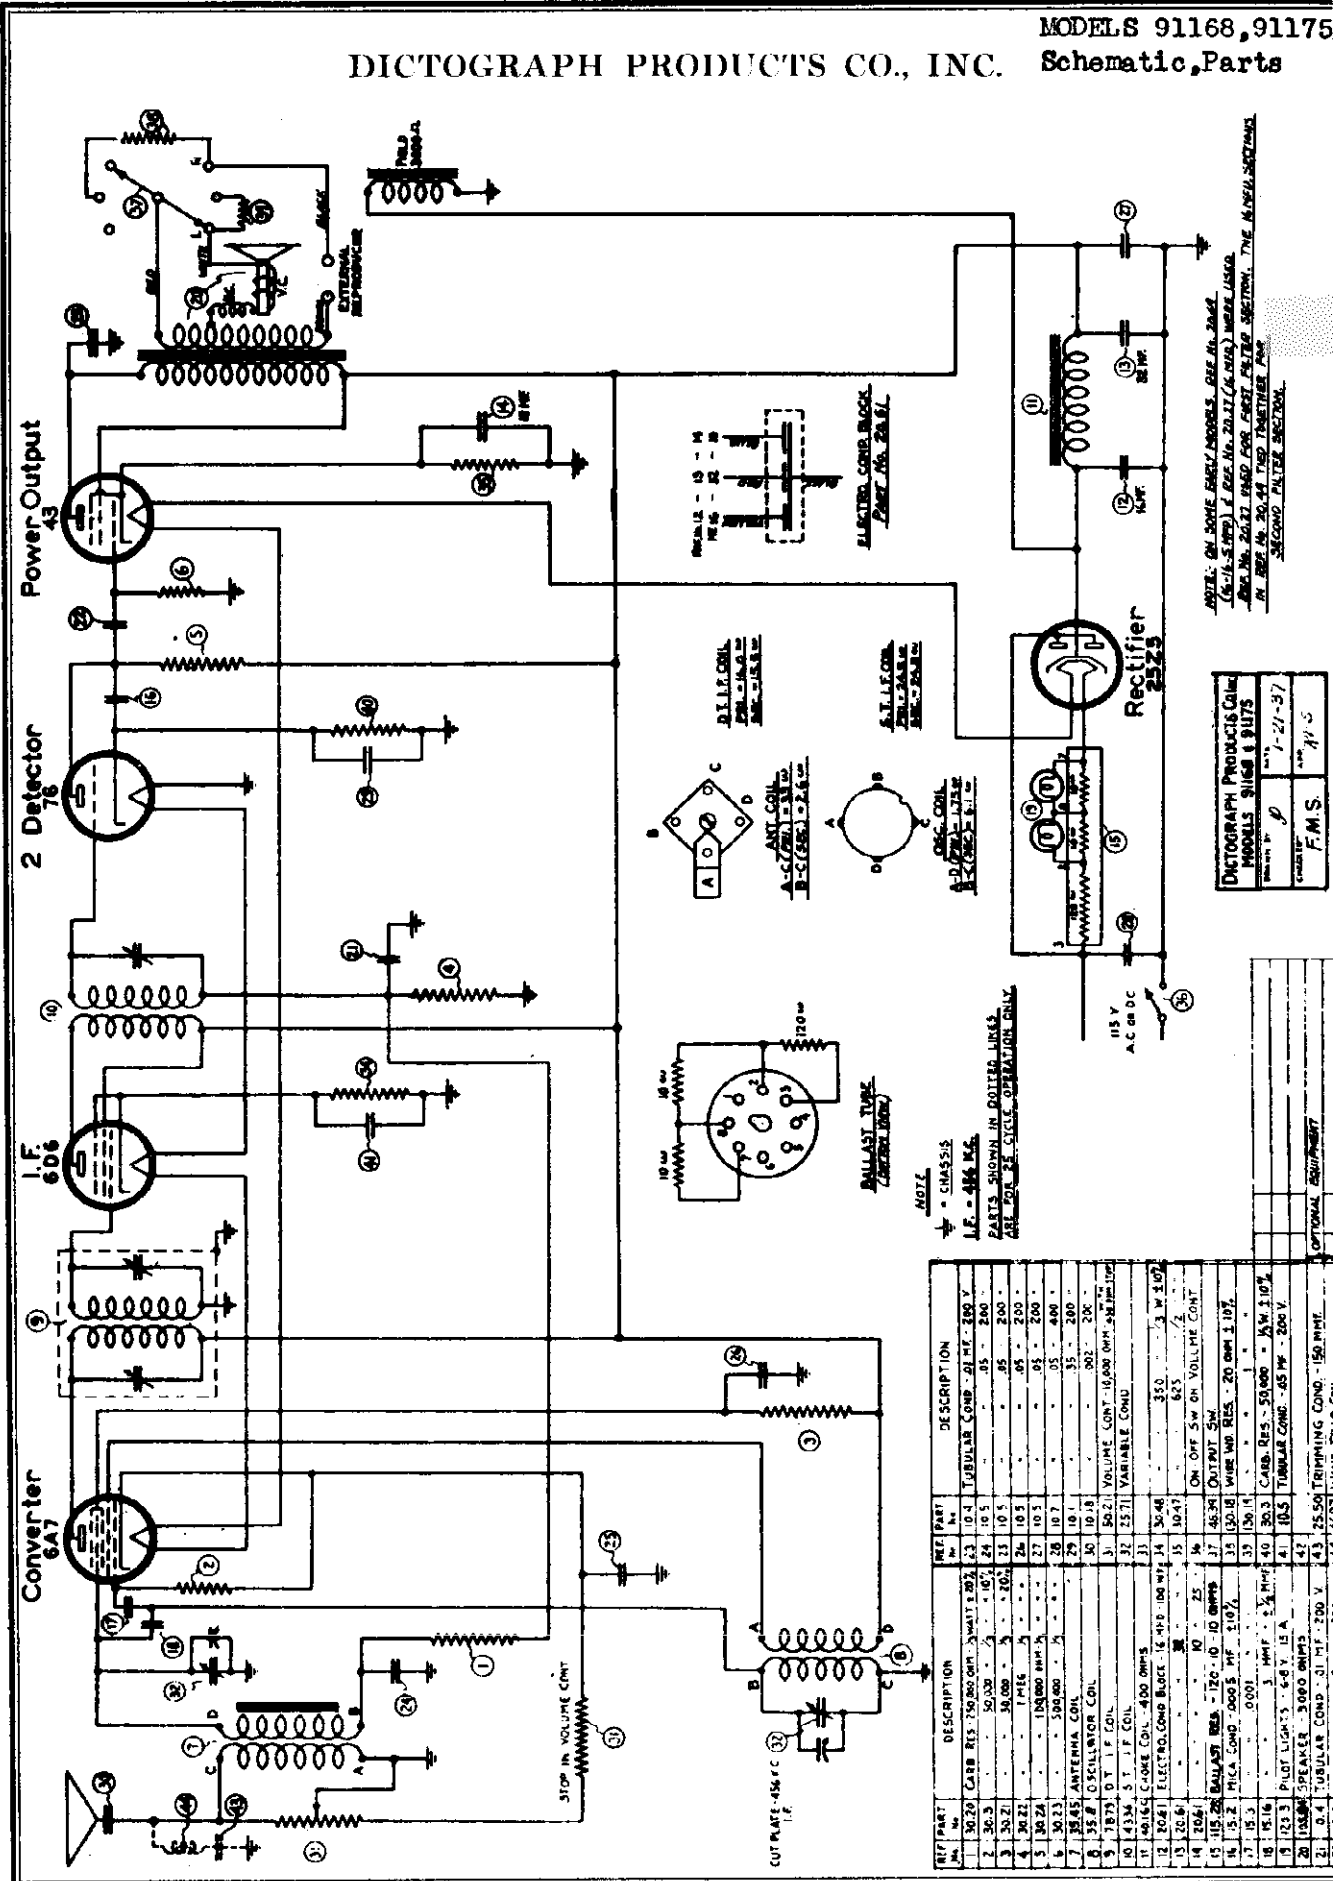

- (a) - Remove the control grid lead of the 6A7 tube and insert a 50,000 ohm (carbon type 1/3 watt) resistor in series with same. Then connect the high potential lead of the signal generator through a .001 mfd. condenser (paper tubular 400 volt type), directly to the control grid of the 6A7 tube.
- (b) - Turn the rotor plates of the ganged variable condenser where no broadcast station carrier is heard (approximately 1000 KC). If this is not possible connect a .1 mfd. condenser (paper tubular) from the oscillator stator section (see sketch) of the ganged variable condenser to chassis.
- (c) - Place an output meter (copper oxide type) across the mystic ear terminals with the speaker control switch in a clockwise position so that variations in signal output can be noted.
- (d) - Place the signal generator in operation, adjust the carrier frequency to 456 KC and regulate the attenuator control of the signal generator so that the output signal is low enough to insure accuracy in adjusting the I.F. condenser.
- (e) - Adjust trimmers T-1, T-2 and T-3 (see alignment layout) to resonance as indicated by the greatest swing on the output meter.

ADJUSTMENT OF THE GANGED VARIABLE CONDENSERS

- (a) - Remove the signal generator connection from the control grid of the 6A7 tube and replace the control grid lead. Then connect the antenna wire of the receiver to the high potential lead of the signal generator through a 200 mmfd. condenser (mica type).
- (b) - Set the dial pointer directly at the last long line at the right hand side of the dial with the ganged variable condenser fully meshed. Then rotate the receiver dial to 1,500 KC.
- (c) - Adjust the carrier frequency of the signal generator to 1,500 KC and, starting with trimmer T-4 and then T-5, adjust each for maximum signal output.

SOCKET VOLTAGES EXCEPT THOSE OF CATHODES ARE MEASURED FROM GROUND USING THE 500 VOLT SCALE OF A 1000 OHM PER VOLT VOLTMETER. ONE SPEAKER FIELD CONNECTED LINE 115V.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	100	50	2.3	100	6.3
6D6	100	100	3.5	—	6.3
6Q7	43	—	1.2	—	6.3
25L6	92	100	6.5	—	25.0

Voltage at 25Z5 cathode—128 volts.
Voltage across speaker field—28 volts.

Tube Data

- The tube complement is as follows:
- 1—6A7, pentagrid oscillator-modulator.
 - 1—6D6, first i-f amplifier.
 - 1—6Q7, diode detector, a-f amplifier, a.v.c.
 - 1—25L6, beam power output.
 - 1—25Z5, dual half-wave rectifier.

Alignment, Notes, Parts

REPLACEMENT PARTS

ADJUSTMENTS

An oscillator with frequencies of 455 and 1400 kc is required. An output meter should be used across the voice coil or output transformer for observing maximum response. Always use as weak a test signal as possible when aligning the receiver.

Location of Coils and Trimmer Adjustments

The first i-f transformer is mounted on top of the chassis deck beside the speaker. The trimmers are accessible through holes in the top of the chassis.
The second i-f transformer is mounted underneath the chassis in the right hand front corner. The trimmers are accessible through holes in the top of the chassis directly in front of the first i-f transformer.
The trimmers for the antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.
The 455 kc wave-trap is mounted on the metal strip at the rear of the chassis directly behind the variable condenser. The trimmer for the 455 kc wave-trap is mounted on the coil and is accessible from the bottom of the chassis.

I-f and Wave-trap Alignment

Rotate the wave-hand switch (located at the rear of the chassis) to the broadcast position, clockwise, and swing the variable condenser to the minimum capacity position. Feed 455 kc to the grid-cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 455 kc through a dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust the wave-trap trimmer for minimum response. (See General Notes, paragraph No. 7.)

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on the chassis) and then the antenna trimmer (on the antenna section) for maximum response. The police band is self-tracking and does not require any adjustment.

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R-12—see schematic) is a resistance wire in the special line cord. The cord will therefore, become warm under normal operating conditions. To insure good heat radiation stretch out the line cord to its full length. Do not attempt to shorten it by cutting.
4. In operating the receiver on d.c. it may be necessary to reverse the line plug for correct polarity.
5. The color coding of the i-f transformer leads is as follows:
Grid—green
Plate—blue
B plus—red
Grid return—black
6. In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.
Where the Flexible Mast is installed permanently, it is urgently recommended that the receiver antenna wire be cut. Leave just enough of this wire to reach from the receiver to the window strip connector.
7. The wave-trap in the receiver has been adjusted for maximum signal rejection at 455 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to chassis with volume control turned on full and no signal. Battery voltage for these readings was 6.1 volts.

Tube	Plate	Screen	Occ. Plate
1A4 r-f	137	83	137
1A4 i-f	137	83	137
1B5/2A5	95	55	—
30	55	—	—
1E7G	135	137	—

Voltage across filaments—2 volts.

To check the bias of the 1E7G tube, measure the voltage from the filament terminal, closest to the screen, of the 30 tube to the negative side of the 20 mf tubular electrolytic condenser. This reading should be 7.6 volts.

To check the bias of the other tubes, measure the voltage from the filament terminal, closest to the screen, of the 30 tube to the grid cap of the 1A4 i-f tube. This reading should be 3 volts.

Six-Tube Battery-Operated Superheterodyne
MODELS P117 and P135
ADJUSTMENTS

An oscillator with frequencies of 466 kc and 1600 kc should be used. An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of I-f Transformers and Trimmers

The first i-f transformer, part number 3HT-287A is in an oblong coil can located on the top of the chassis to the right of the variable condenser. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part number 3HT-288A, is in an oblong coil can located on the top of the chassis directly behind the first i-f tube. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The oscillator, antenna, and r-f trimmers are located on the top of the chassis. The oscillator trimmer is on the rear section of the variable condenser, the antenna trimmer is on the front section of the variable condenser and the r-f trimmer is on the center section of the variable condenser.

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 466 kc to the grid cap of the 1A4 tube.
3. Adjust the four i-f trimmers, repeating for maximum response.
4. Set dial pointer to 1600 kc to the antenna lead through a standard broadcast dummy antenna (a .0002 mf mica condenser may be used as a substitute).
5. Adjust the oscillator trimmer (on rear section of variable condenser) for maximum response.
6. Adjust the r-f trimmer (on center section of variable condenser) for maximum response.
7. Adjust the antenna trimmer (on front section of variable condenser) for maximum response.

GENERAL NOTES

1. The large, oblong metal box on the top of the chassis deck contains the power pack. The function of this power pack is to convert the 4 volt direct current from the storage battery into 140 volt direct current. The vibrator used is of the synchronous type.
2. The illustration on the right indicates the correct battery connections. Three battery clips are attached to the leads emerging from the top of the chassis. One of the two small clips is connected to the positive terminal of the battery. The small clip with the larger terminal should be attached to the negative side of the battery.

Tube Data

The tube complement is as follows:
1—1A4, r-f amplifier
1—1A4, oscillator-modulator
1—1B5/2A5, 2A5 r-f amplifier
1—30, 2A5 filament
1—30, A5 filament
1—30, A5 filament
1—1E7G, push-pull pentode output.

Note that the battery is made up of three cells. The large battery clip should be attached to the positive side of the same cell to which the negative clip is attached. It is important that these battery connections be made correctly. Before turning the receiver on check the connections with the illustration.
3. The color coding of the leads of the i-f transformers is as follows:
P117—blue
Grid—green
B plus—black
Grid return—black
4. With few exceptions the color coding of the general wiring is as follows:
Cathode—white or yellow
Grid—green
Filament and ground—black
Common neg.—black.
5. The color coding of the leads of the power pack is as follows:
A plus—yellow
B plus—red
6. An efficient antenna system (aerial) is necessary to enable a full realization of the merits of the receiver. The Emerson All-Wave Antenna is especially designed for high efficiency and reduction of noise on all frequency ranges. Complete instructions for the installation of this antenna are supplied with each kit.

REPLACEMENT PARTS LIST

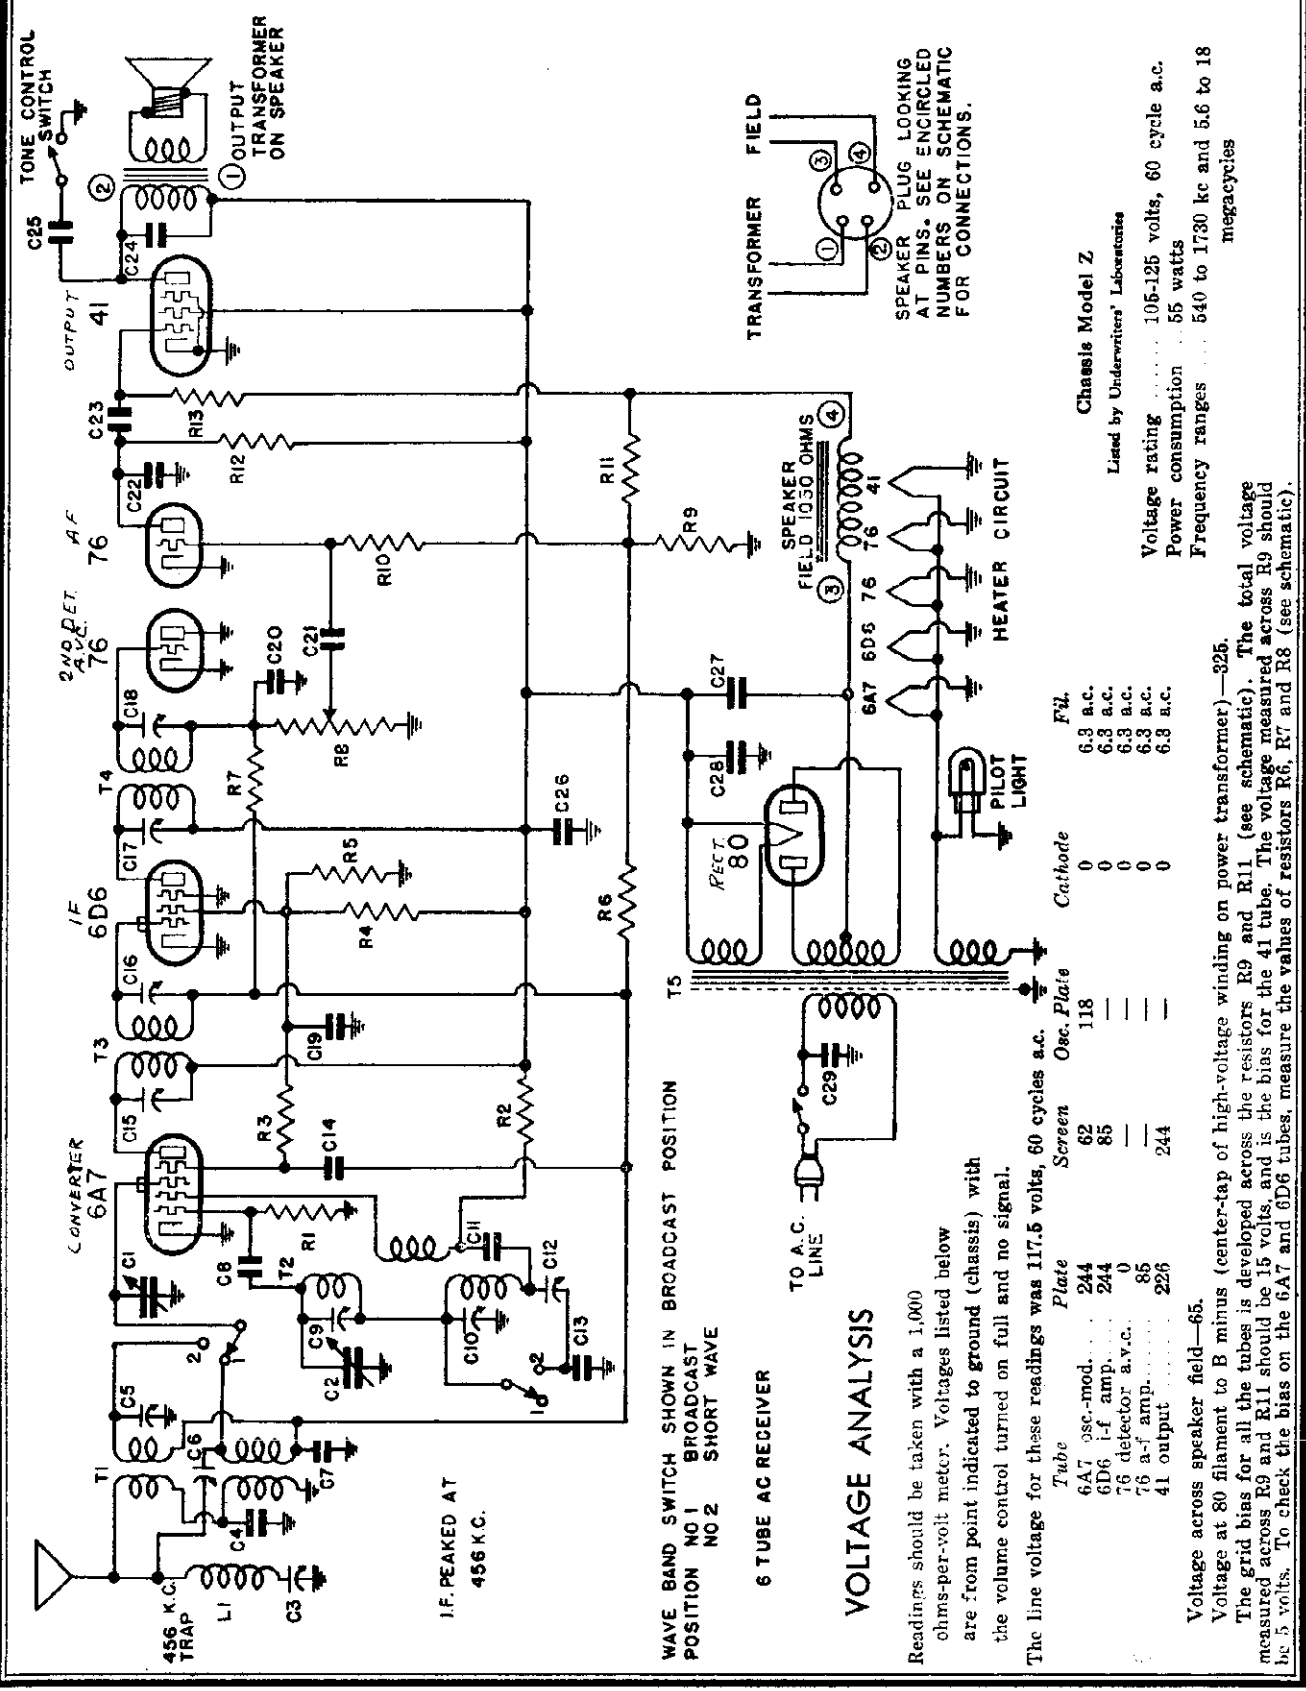

*ITEM	PART NO.	DESCRIPTION	Price as of Aug. 15, 1936
T1	3PT-309	Antenna coil	.85
T2	3HT-288	r-f interstage coil	.75
T3	3HT-287	oscillator coil	1.25
T4	3HT-287A	466 kc first i-f transformer	1.35
T5	3HT-288A	466 kc second i-f transformer	1.35
T6	3PT-310	Power transformer	2.00
L1	2KT-289	Iron-core filter choke (500 ohms)	1.20
L2	2ET-240	Layer-wound "A" choke	.55
L3	3FT-311	Dual r-f choke assembly (170 microhenries each section)	1.50
R1	LR-40	20,000 ohm, 1/4 watt carbon resistor	.16
R2	KR-43	50,000 ohm, 1/4 watt carbon resistor	.16
R3	3PR-268	Volume control (250,000 ohms)	.75
R4	KR-56	500,000 ohm, 1/4 watt carbon resistor	.16
R5	KR-54	100,000 ohm, 1/4 watt carbon resistor	.16
R6	R10	50,000 ohm, 1/4 watt carbon resistor	.16
R7	7K-310	50,000 ohm, 1/4 watt carbon resistor	.16
R8	KR-55	250,000 ohm, 1/4 watt carbon resistor	.16
R9	KR-37	1 megohm, 1/4 watt carbon resistor	.16
R10	IR-120	150 ohm, 1/2 watt wire-wound resistor	.16
R11	3FR-360	200 ohm, 1/2 watt wire-wound resistor	.16
R12	3BR-347	400,000 ohm, 1/4 watt carbon resistor	.16
R13	3BR-106	200 ohm wire-wound center-tapped resistor	.16
C1, C2	RFC-304	Three-range variable condenser	4.15
C3	AC-5	0.1 mf, 200 volt tubular condenser	.30
C4, C21	AC-6	0.0001 mf mica condenser	.20
C5, C11	EC-24A	0.9 mf, 200 volt tubular condenser	.80
C6, C12	BBC-181	Trimmers, part of 3HT-287A, first i-f transformer assembly. (Trimmers can not be supplied separately.)	
C7, C8	BBC-181	Trimmers, part of 3HT-288A, second i-f transformer assembly. (Trimmers can not be supplied separately.)	
C9, C10	AC-7A	0.00025 mf mica condenser	.20
C12, C13, C15	FC-59	0.02 mf, 200 volt tubular condenser	.20
C14, C20	LC-55	0.02 mf, 400 volt tubular condenser	.20
C16, C19, C30	LC-55	0.002 mf, 600 volt tubular condenser	.20
C17, C18	3FC-374	20 mf, 25 volt tubular dry electrolytic condenser	.80
C22	3FC-310	0.25 mf, 200 volt tubular condenser	.20
C23	HC-13	0.01 mf, 500 volt tubular condenser	.20
C24	3TC-377	0.01 mf, 500 volt tubular condenser	.20
C25	3TC-377	0.01 mf, 500 volt tubular condenser	.20
C26	3PC-307	Dial 8 mf, 300 volt air electrolytic condenser	3.00
C27	KPC-123	0.1 mf, 400 volt air electrolytic condenser	.20
C28	KPC-123	0.5 mf, 120 volt tubular condenser	.50
C29	2KC-236	Trimmers on three-range variable condenser. (Trimmers can not be supplied separately.)	
C31, C32	3PB-214	5/4 permanent magnet dynamic speaker (for Model P-117)	8.25
C33	3PB-222	10 permanent magnet dynamic speaker (for Model P-135)	11.00
C34, C35	3TS-145F	Tone control switch	.85
C36	3PS-215	Power switch	.75
C37	3PW-31	Battery cable	1.35
C38	AL-2	Pilot light 2.5 volt, 0.5 amp Mazda No. 41	.20
C39	3PZ-452	Dial face	.75
C40	3PZ-456	Dial drive belt	.20
C41	3CZ-387	Dial drive shaft and pulley	.40
C42	3CZ-387	Dial drive spring	.05
C43	3CZ-340	Idler spring	.05
C44	3CZ-341	Condenser shaft pulley	.10
C45	3PZ-363	Dial pointer	.10
C46	3CZ-350	Electrochone with crystal	1.05

VOLTAGE ANALYSIS

Readings should be taken with a 1,000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal.

The line voltage for these readings was 117.5 volts, 60 cycles a.c.

Tube	Plate	Screen	Osc. Plate	Cathode	Fil.
6A7	244	62	118	0	6.3 a.c.
6D6	244	85	—	0	6.3 a.c.
76	0	—	—	0	6.3 a.c.
76	85	—	—	0	6.3 a.c.
41	228	244	—	0	6.3 a.c.

Voltage across speaker field—65.
Voltage at 80 filament to B minus (center-tap of high-voltage winding on power transformer)—326.
The grid bias for all the tubes is developed across the resistors R9 and R11 (see schematic). The total voltage measured across R9 and R11 should be 15 volts, and is the bias for the 41 tube. The voltage measured across R9 should be 5 volts. To check the bias on the 6A7 and 6D6 tubes, measure the values of resistors R6, R7 and R8 (see schematic).

Tube Data

The tube complement is as follows: 6A7, pentagrid oscillator-modulator; 6X6, audio detector and a.v.c. (behind second I.F. transformer); 6AR5, audio amplifier output; 6AV6, full-wave rectifier.

REPLACEMENT PARTS

Table with columns: Part No., Description, Price. Lists various electronic components like capacitors, resistors, transformers, and tubes with their respective prices.

Six-Tube, A.C., Dual-Wave Superheterodyne MODELS Z117, Z122, Z133, Z135, Z141, Z150, Z159, and Z160 ADJUSTMENTS

An oscillator with frequencies of 466, 900, 1800 and 3600 kc. should be used. An output meter should be used across the voice coil or output transformer for observing maximum response. If the circuit is at all disturbed, both the broadcast and short-wave bands must be aligned.

Location of Coils and Trimmer Adjustments

The two I.F. transformers are located on top of the chassis deck. The second I.F. is the one directly behind the variable condenser. The four trimmers are located as follows: 6A7 trimmer is located in the top of the chassis deck near the antenna trimmer.

I.F. and Wave-trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 466 kc. through a 0.02 mf. paper condenser to the grid tap of the 6A7 tube (clockwise).

Short-Wave Alignment

Use a 400 ohm dummy antenna (a 400 ohm non-inductive resistor in series with the test oscillator antenna lead) when aligning the short-wave bands. Feed 16,000 kc. to the antenna and adjust the short-wave oscillator trimmer (nearest the front board variable condenser) for maximum response, and then adjust the short-wave antenna trimmer (nearest the front board variable condenser) for maximum response.

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be substituted.) Rotate the wave-band switch to the broadcast (clockwise) position. Set the dial pointer at 60 and feed 600 kc. Adjust the broadcast antenna trimmer (in corner next 6A7 tube) for maximum response. Move the dial pointer to 160 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front board variable condenser) for maximum response.

GENERAL NOTES

- 1. The wave-trap in the receiver has been adjusted for maximum signal rejection at 466 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
2. The receiver should never be turned on with either the speaker plug or the 41 tube out of their sockets, since the rapid rise in rectifier voltage would damage the electrolytic condensers.
3. The pilot light may be replaced by plugging the push-on socket of the dial and uncracking the bulb. It is not necessary to remove either the dial or chassis from cabinet.
4. In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not flex freely, and do not allow any part of the dial assembly to touch the cabinet. If not properly mounted, the receiver may become microphonic.
5. The color coding of the 82T-345 power transformer leads is as follows: (See production changes for color coding of power transformer previously used.)
Primary—two black, two red leads
Secondary—two black, two red leads
High voltage sec. center tap—red and yellow
6. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. The Emerson All-Antenna is especially designed for high efficiency and reduction of noise on all frequency ranges. Complete instructions for the installation of this antenna are supplied with each kit.

PRODUCTION CHANGES

Early Model Z-150 receivers differed from the schematic diagram as follows:

- a. C27 is a 2 mf. 450 volt dry electrolytic condenser.
b. C28 is a 8 mf. 450 volt dry electrolytic condenser.
c. A 80,000 ohm 1/2 watt carbon resistor (R12) of the 75 W type.
d. A 8 mf. 150 volt dry electrolytic condenser is connected from the screen-grid of the 6D6 I.F. amplifier to ground.

Later Model Z-150 receivers differ from the schematic diagram as follows:

- a. C27 is a 2 mf. 450 volt dry electrolytic condenser.
b. C28 is a 24 mf. 400 volt dry electrolytic condenser.
c. A .25 mf. 250 volt condenser is connected from the screen-grid of the 6D6 I.F. amplifier to ground.
In receiver bearing serial numbers below 1,072,957:
a. The power transformer is part No. Z11-258. The color coding of this transformer is as follows:
Primary—two black, two red leads
Secondary—two black leads
High voltage secondary—two black leads
High voltage secondary center tap—yellow lead.

When number located in the schematic diagram, the article on the schematic diagram.

Early receivers differed from the schematic diagram as follows:

- A 50,000 ohm resistor, by-passed with a 0.1 mf. 200 volt condenser, was used in the plate circuit of the 7B tube as an A-C filter.
- The motor of C28 was returned to ground instead of the coil, as shown on the schematic.
- The motor of C28 was 2000 ohm carbon resistor.
- The 6A7 and 6D6 ballast tubes, R2 was a 150 ohm, 1/2 watt wire-wound resistor, and C7 was 0.15 mf. 200 volt condenser. C28 and C26 were not in the circuit.
- C1 was an 0.61 mf. 200 volt condenser.

PRODUCTION CHANGES

The tube complement is as follows:
1-6A7, pentagrid oscillator-modulator
1-4D6, first I-F amplifier
1-6BE6, second I-F amplifier, automatic volume control
1-5Y4, motor speed motor, ac-operated
1-3X7, motor speed motor, ac-operated
1-3Z5, dual half-wave rectifier
1-8CR241, ballast tube (E-16 on schematic).

Combination Phonograph and
A.C.-D.C. Dual-Wave Superheterodyne
SIX TUBES, INCLUDING BALLAST TUBE

Model G-127
RECEIVER ADJUSTMENTS

An oscillator with frequencies of 456, 690, 1416 and 15,000 kc should be used. In addition an output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments

The broadcast antenna coil, the short-wave antenna coil and the 456 kc wave trap are one assembly mounted under the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis deck. The trimmer for the antenna coil is located at the right-hand corner of the wave trap. The trimmer for the broadcast antenna coil and the trimmer farthest from the chassis front is for the 456 kc wave trap.

The broadcast oscillator and short-wave oscillator coils are wound on one tubing and mounted on the inside of the rear chassis wall. The trimmers for these coils are accessible through two holes in the rear chassis wall. The left-hand trimmer (looking at the rear wall) is for the short-wave oscillator coil and the right-hand trimmer is for the broadcast oscillator coil.

The 6A7 and 6D6 ballast tubes are in oblong coil cans located on the top of the chassis. The first I-F transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the top of the chassis.

The broadcast series loading condenser is located on the rear wall of the chassis below the 6A7 tube.

I-F Transformer and Wave-Trap Alignment

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the first I-F trimmer for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer (rear screw beside variable condenser) for minimum response.

Short-Wave Alignment

Use a dummy antenna (400 ohm resistor) when aligning the short-wave coils. Rotate the wave-band switch counter-clockwise to the short-wave position and set the dial pointer to 13 megacycles. Feed 15 megacycles through the dummy antenna and adjust the trimmer for maximum response. Repeat this procedure for maximum response. The variable condenser should be rotated while adjusting the antenna trimmer. (Rotate variable condenser rotor shaft back and forth through a small arc).

Broadcast Alignment

Rotate the wave-band switch to the broadcast position, clockwise, and set the dial pointer at 64. Feed 640 kc through a standard dummy antenna (a 4000 ohm resistor may be used as a substitute). Adjust the broadcast series loading condenser (on rear chassis wall, below 6A7 tube) for maximum response. Move pointer to 1416, feed 1416 kc and adjust the broadcast oscillator trimmer (right-hand screw on rear chassis wall) for maximum response. Repeat this procedure for 1416 kc and readjust the series loading condenser reading the variable condenser for maximum response. Repeat this procedure for 640 kc and readjust the series loading condenser reading the variable condenser for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signal. Always choose the minimum capacity peak on oscillator trimmer and maximum capacity peak on antenna trimmer. Always use as weak a test signal as possible during alignment. Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

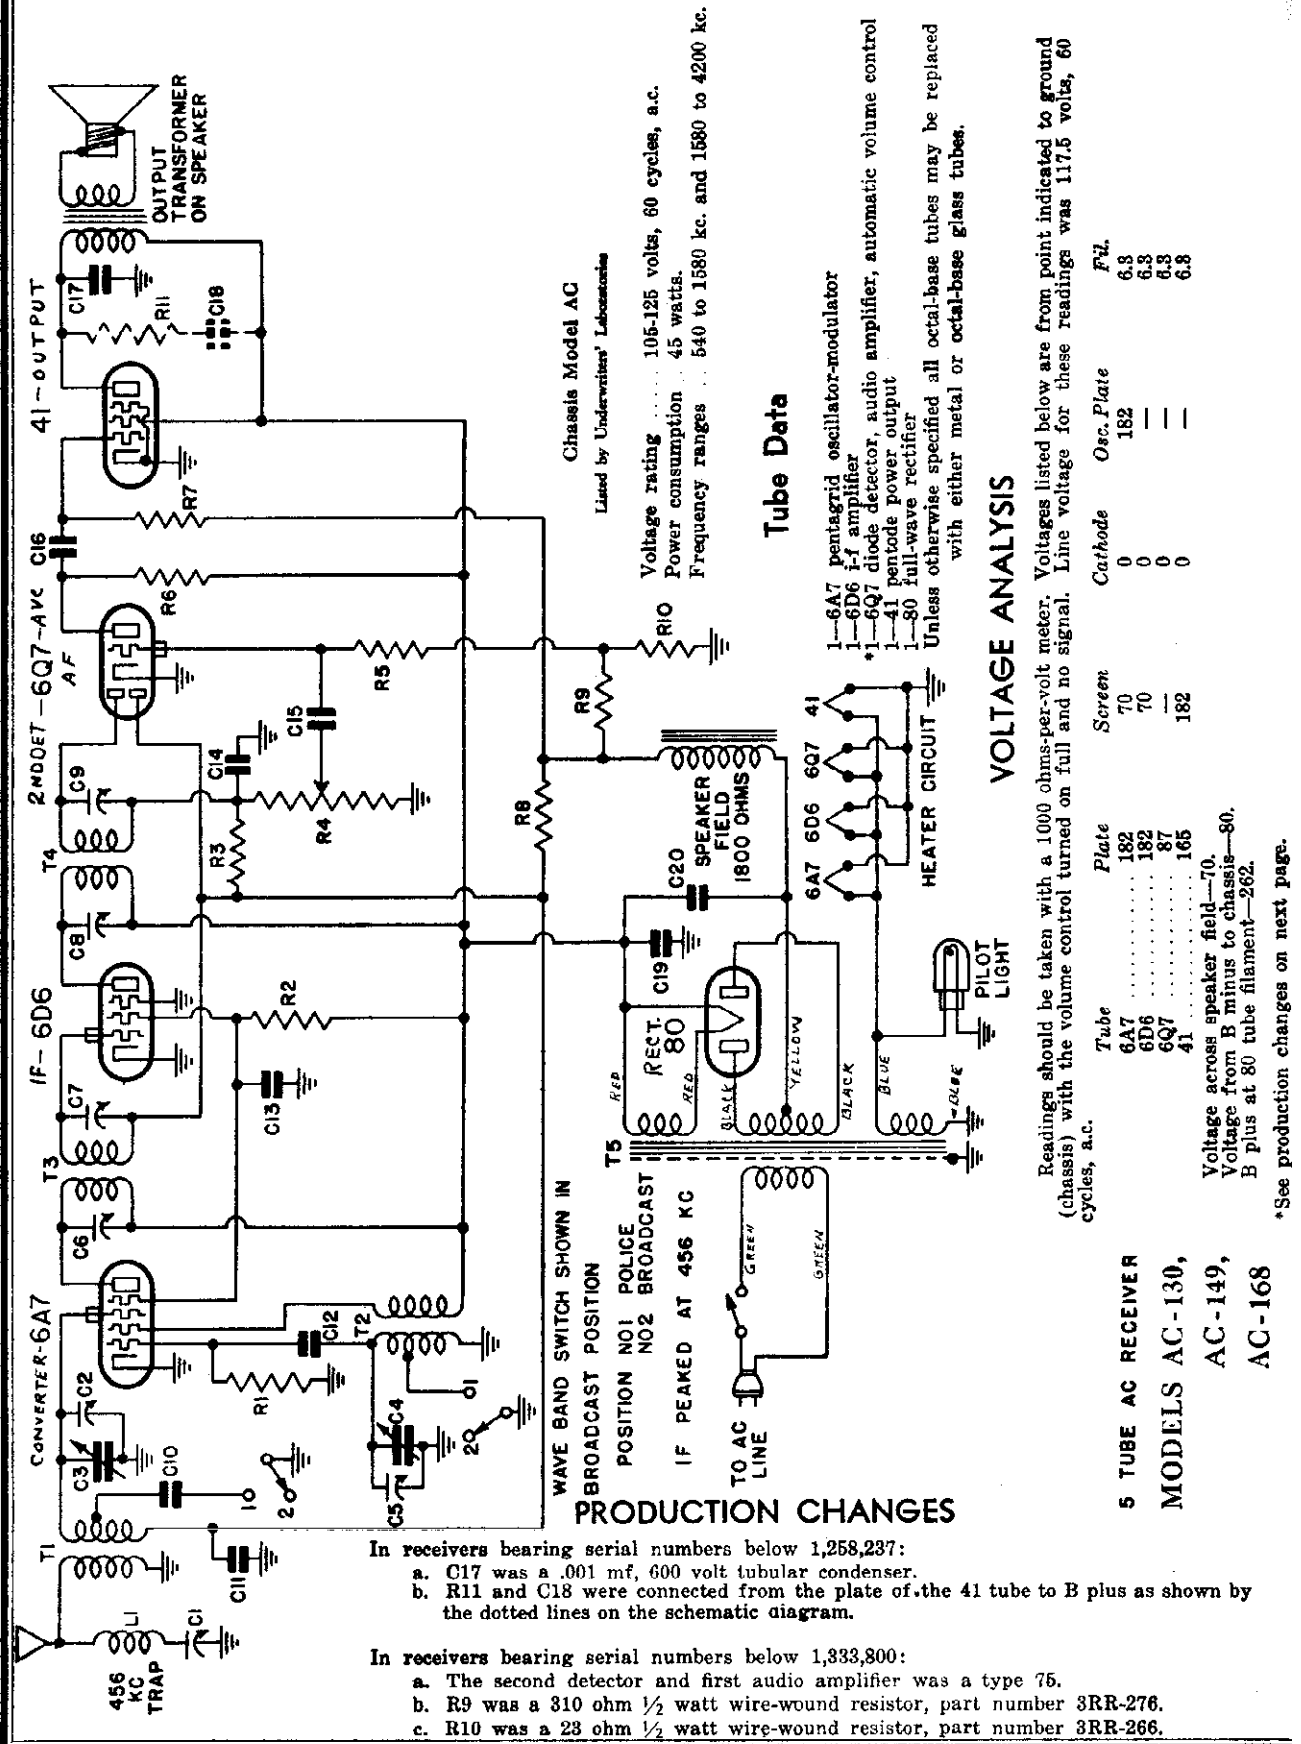

GENERAL NOTES

- If replacements are made or the wiring described in the rf portion of the circuit, the receiver should be carefully re-aligned.
- One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to connect in contact with any metal part of the receiver.
- The filament dropping resistor (R14 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
- When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
- The two I-F transformers are held to the chassis by snap-on fasteners. To remove an I-F transformer all the leads under the chassis, punch together the prongs of the snap-on fastener and lift the I-F can from the chassis.
- The color coding of the I-F transformer leads is as follows:
Plate—blue
Grid—green
B plus—red

- The phonograph motor has been adjusted at the factory to turn at a speed of 78 r.p.m. The speed may be checked by counting the turns per minute or by using a stroboscope disc and a neon light (the stroboscope method will only work when the neon bulb is lighted from a 60 cycle a.c. supply).
- An a.c.-d.c. switch is provided to switch the motor for a.c. or d.c. power supply. It is important that this switch be in the proper position for the power supply available.

Alignment, Notes, Parts

GENERAL NOTES

1. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
2. The receiver should never be turned on with the 41 tube out of its socket since the rapid rise in rectifier voltage would damage the electrolytic condensers.
3. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
4. The color coding of the leads of the i-f transformers, is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red
5. The color coding of the power transformer leads is as follows:

Primary—two green leads	6.3 v. sec.—two heavy blue leads
High voltage sec.—two black leads	5 v. sec.—two heavy red leads
High voltage sec. center tap—yellow	
6. With a few exceptions, the color coding of the general wiring is as follows:

Plate—blue	A.v.c. and cathode—white or yellow
B plus—red	Grid—green
Screen—brown	Filament and ground—black
7. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.
 In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.

ADJUSTMENTS

An oscillator with frequencies of 456 and 1400 kc is required.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Always use as weak a test signal as possible when aligning the receiver.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f transformer is the one directly behind the variable condenser. The trimmers for the two i-f transformers are available through holes in the tops of the cans.

The trimmers for the antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

The 456 kc wave-trap is mounted on the front chassis wall beneath the variable condenser. The trimmer for the 456 kc wave-trap is mounted on the coil and is accessible from the bottom of the chassis.

I-f and Wave-Trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc, through a 0.02 mf paper condenser, to the grid cap of the 6A7 tube (do not remove the grid clip from the tube). Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) and adjust the wave-trap trimmer for minimum response. (See General Notes.)

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

	3FZ-399	Clip for dial crystal (for Model AC-149)	.01

NOTE: The Model AC-149 should be aligned with the chassis bottom plate in place.

†These trimmers are part of coil assemblies and can not be supplied separately.
‡These trimmers are part of variable condenser and can not be supplied separately.

When ordering replacement parts specify part numbers.
*Item number locates the article on the schematic diagram.

EMERSON RADIO & PHONO. CORP.

The tube complement is as follows:
 1—1C6 oscillator-modulator
 1—1A4 1st i-f amplifier
 1—1B5-26S 2nd detector, a.v.c., a-f amplifier
 1—30 a-f amplifier
 1—1F4 pentode output

TO TUBE FILAMENTS
 AS INDICATED BY X ABOVE RII

VOLTAGE ANALYSIS

Readings should be taken with a 1,000 ohms-per-volt meter. The voltages listed below are from point indicated to A minus with volume control turned on full and no signal. The battery voltages for these readings were as follows: "A" battery 3 volts, "B" battery 135 volts.

Tube	Plate	Screen	Osc. Plate	Fil.
1C6	106	106	57	2.0
1A4	106	57	—	2.0
1B5-26S	75	—	—	2.0
30	90	—	—	2.0
1F4	127	18K	—	5.0

6 TUBE BATTERY RECEIVER

IF PEAKED AT 456 KC.

MODELS AJ130, AJ137, AJ149

Chassis AJ

Alignment, Notes

EMERSON RADIO & PHONO. CORP.

MODELS AJ-130, AJ-137, and AJ-149

CHASSIS MODEL AJ

Current drain "A" battery—42 amps.
 "B" battery—.016 amps. with no signal
 Frequency range 540 to 1730 kc.

GENERAL NOTES

1. The battery complement should be as follows:

Type	No. Req.	Portable (Small Batteries)		
		Eversady Part No.	Burgess Part No.	Ray-o-vac Part No.
1½ volt "A"	2	7111	4FA	6 Railroad
45 volt "B"	3	762 (plug-in type)	5308 (plug-in type)	5308 (plug-in type)

Home (Heavy Duty Batteries)

3 volt "A"	1	X-125	20F2	P9403
45 volt "B"	3	385 (plug-in type)	22308 (plug-in type)	P3303 (plug-in type)

The batteries indicated above for portable use are chosen for size so that the entire complement can be housed by the portable cabinet. In general, it will be found that the "B" batteries will last somewhat longer than the "A" batteries.

2. The receiver is designed for an "A" supply of 2 to 3 volts. If a 2 volt storage battery is used, its positive terminal should be connected to the terminal marked "2" on the metal clad ballast resistor. If a 2½ volt air-cell battery is used, it should be connected to the terminal marked "2.5". A 3 volt supply should be connected to the terminal marked "3".
3. The i-f transformers are of the snap-on type. To remove, unsolder all leads under the chassis, pinch together the prongs of the snap-on fastener and lift out.
4. The color coding of the i-f transformer leads is as follows:
- | | |
|-------------------|------------|
| Grid—green | Plate—blue |
| Grid return—black | B plus—red |
5. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.

ADJUSTMENTS

An oscillator with frequencies of 456 and 1600 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response. If the circuit is at all disturbed, the receivers must be realigned.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on the oscillator trimmer and the maximum capacity peak on the antenna trimmer. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The antenna and oscillator trimmers are located on the right hand side of the variable condenser. The rear trimmer is the oscillator trimmer.

On portable model AJ-137, the 456 kc wave-trap is located below the chassis deck, directly underneath the variable condenser. Its trimmer is accessible through a hole in the bottom plate.

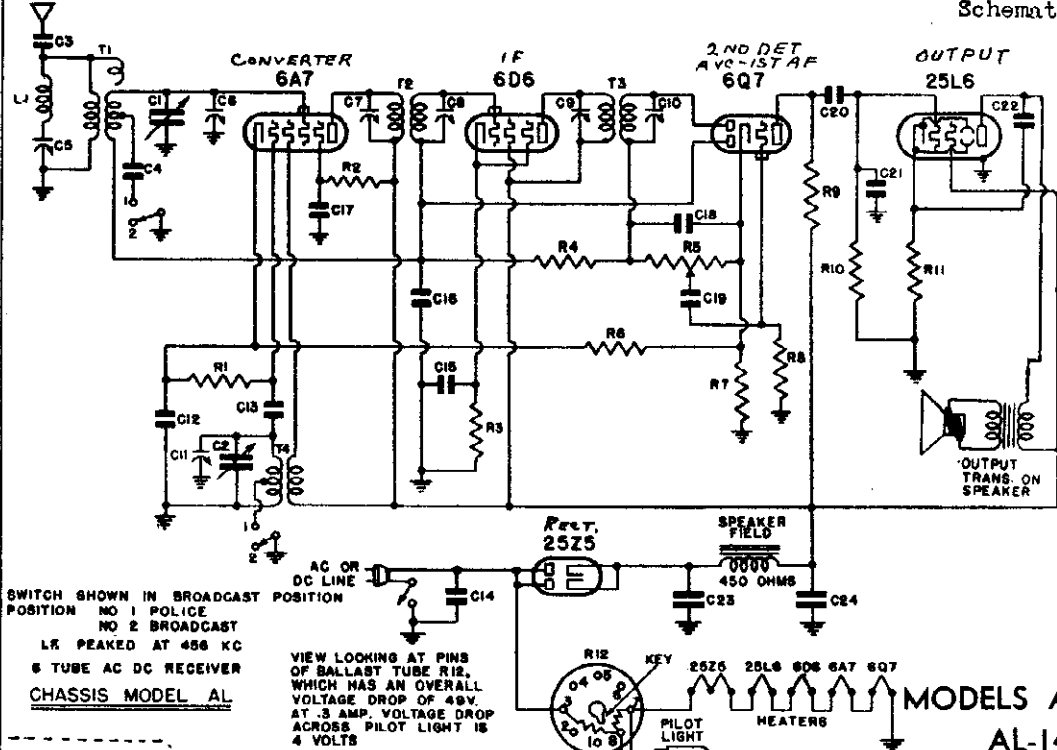

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 456 kc to the grid cap of the 1C6 tube.
3. Adjust the four i-f trimmers, repeating for maximum response.
4. If the receiver is portable model AJ-137, feed 456 kc to the antenna through a standard dummy antenna (a .0002 mf mica condenser may be substituted) and adjust the wave-trap trimmer for minimum response.
5. Set dial pointer to 1600 and feed 1600 kc to the antenna lead through a standard broadcast dummy antenna (a .0002 mf mica condenser may be used as a substitute).
6. Adjust the oscillator trimmer (on rear section of variable condenser) for maximum response.
7. Adjust the r-f trimmer (on front section of variable condenser) for maximum response.

When ordering replacement parts specify part numbers.

GENERAL NOTES

- 1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to connect to the chassis base.
3. The dummy antenna should be used for alignment purposes. It is a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on i.c. it may be necessary to fasten the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f transformer all the leads under the chassis, pinch together the spring contact and lift the top can from the chassis.
6. The color coding: Grid-green; Grid-return-black; B plus-red.

The receiver is shipped with an attached antenna wire. In some locations (especially local stations) the addition of a very large dummy antenna will improve the receiver's performance. The Emerson Flexible dummy antenna for Model W-30 has been especially designed for Emerson receivers, featuring compactness and portability while at the same time retaining a high efficiency from the standpoint of performance. Since it functions as an outside antenna the Flexible Mast will substantially improve the receiver performance. Where the Flexible Mast is installed permanently, it is urgently recommended that the receiver be aligned with the dummy antenna in place. This will prevent outside antenna wire from being supplied with each kit connector. Instructions for the installation of this compact dummy antenna are included in the receiver's manual.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 466 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

ADJUSTMENTS

An oscillator with frequencies of 172, 345, 466, 600 and 1400 kc should be used. An output meter should be used across the output terminals of the oscillator. The voltage across the output terminals should be 100 volts. The wave oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals. The last motion in adjusting trimmers should always be a tightening one, not a loosening one. Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up a ways or use a weak last signal as possible during alignment. Use a standard dummy antenna for aligning either of the bands. A .0001 mf condenser may be used for either the broadcast or long-wave band dummy antennas.

CHASSIS MODEL AL

Location of Coil and Trimmer Adjustments on the Model AL

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser; the trimmers for these transformers are accessible through holes in the tops of the cans. The 466 kc wave-trap is mounted on the right side of the front chassis wall. Its trimmer is accessible through a hole in the bottom plate. The broadcast antenna and oscillator coils are wound on one form and are mounted underneath the chassis. The antenna coils are accessible through holes in the front chassis wall. The trimmer for the broadcast antenna and oscillator coils are located on the rear wall of the chassis deck near the variable condenser. The trimmer for the broadcast antenna and oscillator coils are located on the front section of the chassis deck. The trimmer for the broadcast antenna and oscillator coils are located on the front section of the chassis deck. The trimmer for the broadcast antenna and oscillator coils are located on the front section of the chassis deck. The trimmer for the broadcast antenna and oscillator coils are located on the front section of the chassis deck.

CHASSIS MODEL ALLW

Location of Coils and Trimmer Adjustments on the Model ALLW

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans. The broadcast antenna coil, the long-wave antenna coil and the 466 kc wave-trap are on one assembly mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of chassis deck. The trimmer for the wave-trap is on the central trimmer. The trimmer for the broadcast antenna and oscillator coils are wound on one form and are mounted underneath the chassis below the variable condenser. The trimmers for the broadcast antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil; the trimmer on the left side of the rear chassis wall. The hexagon nut is the adjustment for the long-wave band and the screw in the center of this nut is for the broadcast band.

i-f Transformer and Wave-Trap Alignment for ALLW

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 466 kc to the grid cap of the 6AV tube and adjust the four i-f trimmers for maximum response. Feed 1400 kc to the antenna and adjust the wave-trap trimmer for minimum response.

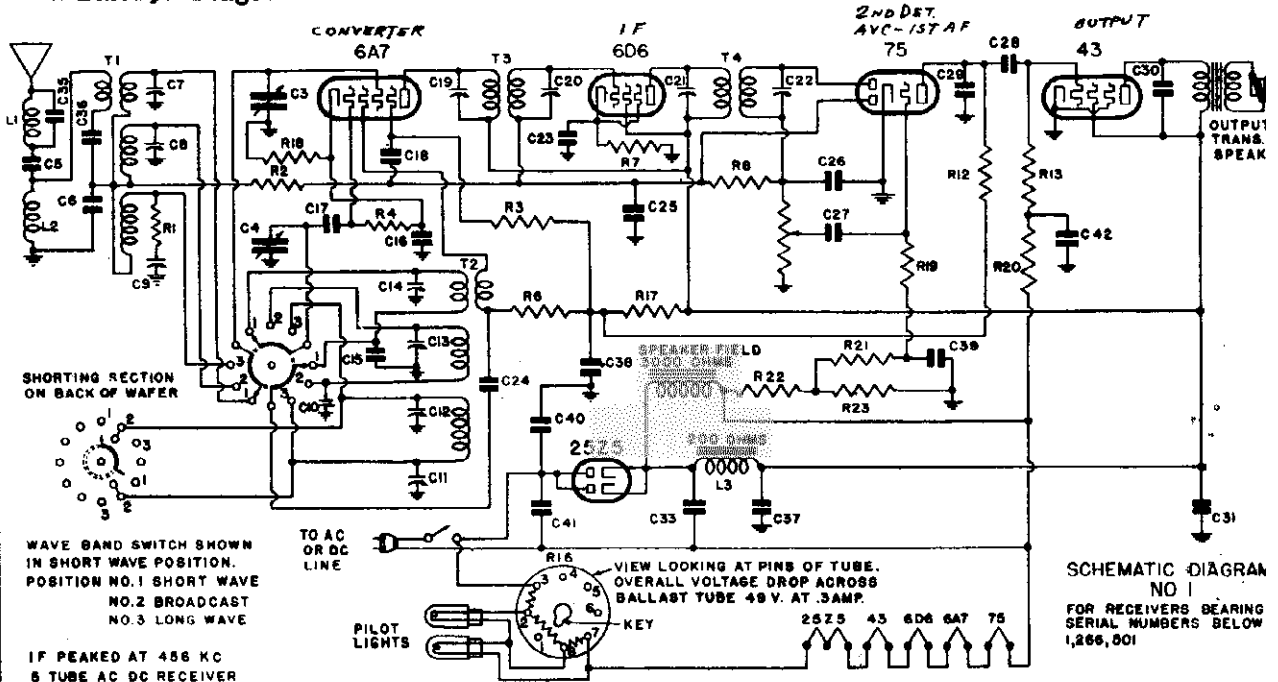

Broadcast Alignment for Model ALLW

Rotate the wave-band switch clockwise to the broadcast position and set dial pointer to 60. Feed 600 kc through a .0001 mf condenser. Adjust padding condenser (slotted screw on dual unit) for maximum response. Move pointer to 1400. Feed 1400 kc and adjust broadcast oscillator trimmer (on front section of gang) and broadcast antenna trimmer.

EMERSON RADIO & PHONO. CORP.

MODEL AAL13
Chassis AA

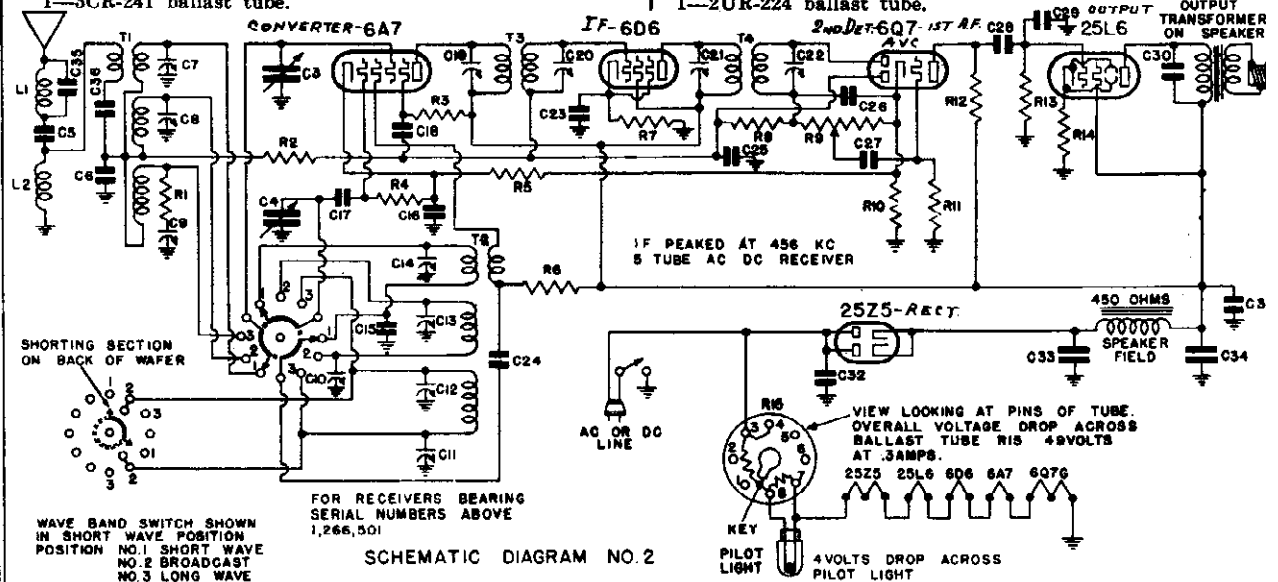

The tube complement for receivers bearing serial numbers below 1,266,501 is as follows:

- 1-6A7 pentagrid oscillator-modulator
- 1-6D6 first i-f amplifier
- 1-75 diode detector, a.v.c., audio amplifier
- 1-43 pentode power output
- 1-25Z5 dual half-wave rectifier
- 1-3CR-241 ballast tube.

The tube complement for receivers bearing serial numbers above 1,266,501 is as follows:

- 1-6A7 pentagrid oscillator-modulator
- 1-6D6 first i-f amplifier
- 1-6Q7 diode detector, a.v.c., audio amplifier
- 1-25L6 beam power output
- 1-25Z5 dual half-wave rectifier
- 1-2UR-224 ballast tube.

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

The following are voltages for receivers bearing serial numbers below 1,266,501:

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	96	35	0.6	57	6.3
6D6	96	78	2	—	6.3
75	35	—	0	—	6.3
43	85	96	0	—	24

Voltage across speaker field—125
Voltage across filter choke—11.1

The bias for the 75 and 43 is developed across resistors R22 and R23 (see schematic diagram). The voltage across R22 is 11 volts and the voltage across R23 is 1 volt.

The voltage drop across the ballast resistor (R16—see schematic) is 49 volts between pins 3 and 7.

The following are voltages for receivers bearing serial numbers above 1,266,501:

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	100	42	1.6	75	6.3
6D6	100	100	3.6	—	6.3
6Q7	36	—	0.8	—	6.3
25L6	95	100	6.7	—	24

Voltage across speaker field—27.5

The voltage drop across the ballast resistor (R16—see schematic) is 49 volts between pins 3 and 7.

REPLACEMENT PARTS LIST

NOTE: Schematic No. 1 applies to receivers bearing serial numbers below 1266501. Schematic No. 2 applies to receivers bearing serial numbers above 1266501.

Table with columns: Part No., Schematic No. 1, Schematic No. 2, Description, Price. Lists various electronic components like capacitors, resistors, and coils.

When ordering replacement parts specify part numbers.

*Item number locates the article on the schematic diagram. †These trimmers are part of the coil assembly and are not to be supplied separately. ‡When ordering pointer specify if screw-on or push-on type.

MODEL AA-131

Chassis Model AA

- Voltage rating 105-125 volts, a.c. or d.c.
Power consumption 50 watts
Frequency range 150 to 375 kc, 640 to 1600 kc, 5.7 to 37.5 mc.

GENERAL NOTES

- 1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a...

ADJUSTMENTS

An oscillator with frequencies of 150, 350, 450, 600, 1500 and 16,000 kc should be used. An output meter should be used across the voice coil or output transformer for checking maximum response.

Location of Coils and Trimmers

The antenna coils for the three bands are wound on one form and mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis.

I-f Alignment

Rotate the wave-band switch to the medium-wave (central) position and set the variable condenser to minimum. Feed 450 kc to the grid cup of the 6A7 tube through a .02 mf paper condenser, (do not remove the grid clip from the tube). Adjust the four I-F trimmers for maximum response.

Long-Wave Alignment

With the wave-band switch at long-wave (clockwise) position set the dial pointer at 15 and feed 150 kc to antenna. Adjust the long-wave series pecker (hex nut on dial pointer) for maximum response. Move pointer to 35 and feed 850 kc to antenna.

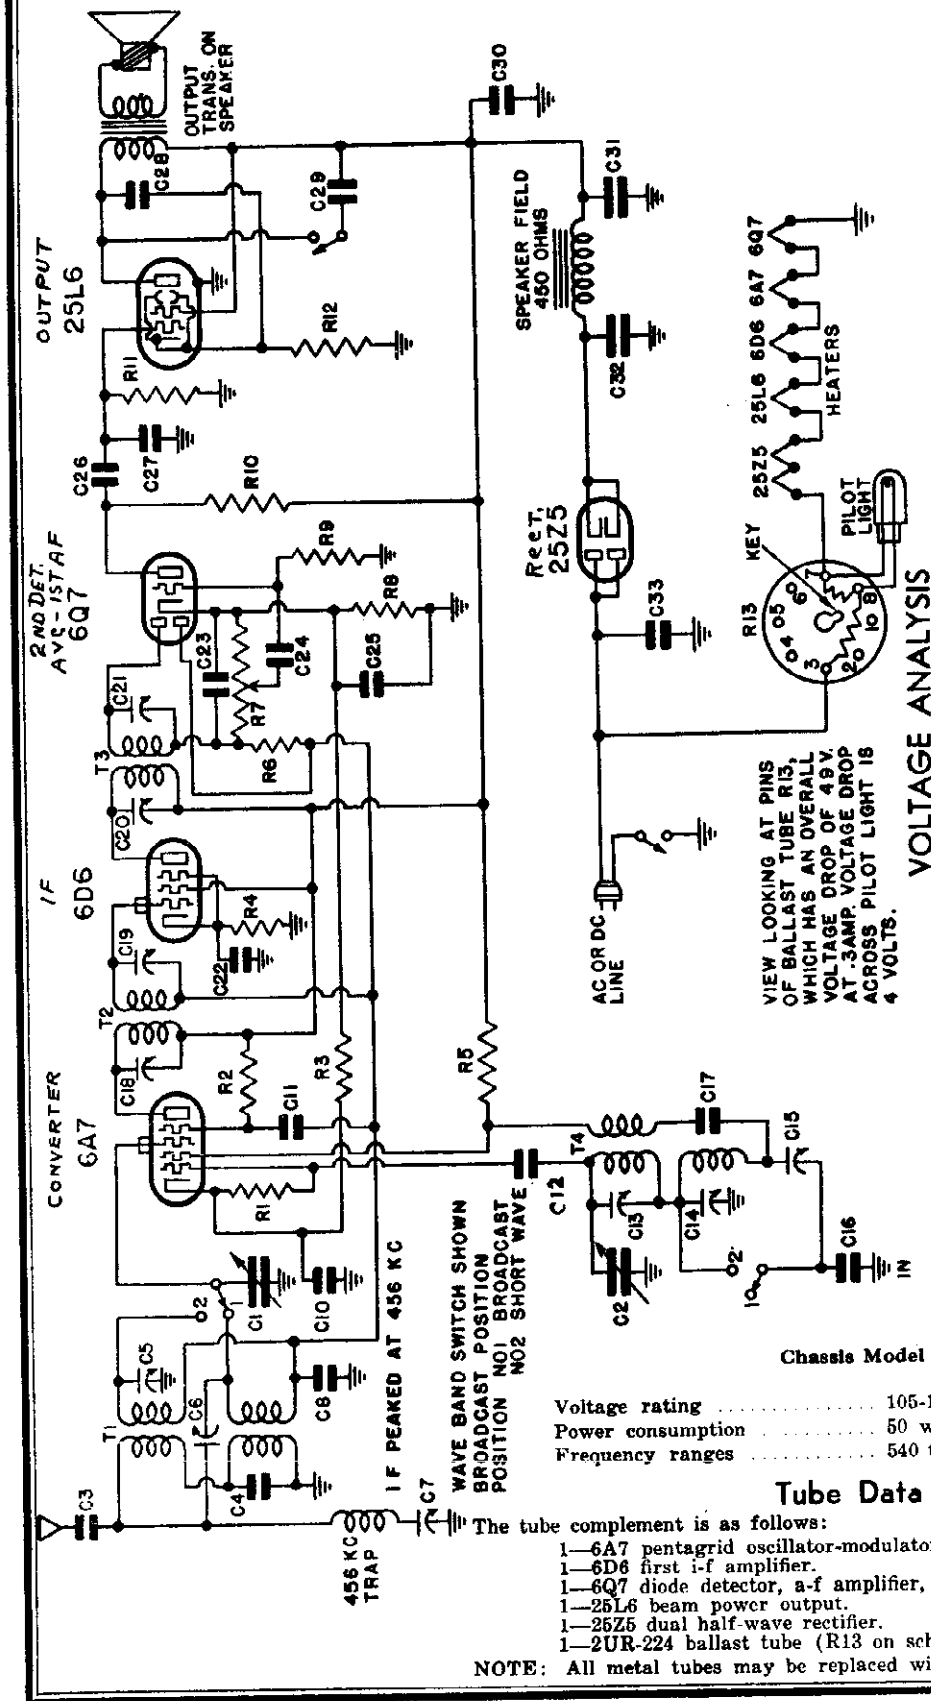

Medium-Wave Alignment

Set switch at medium-wave (central) position and dial pointer at 80. Feed 600 kc to antenna and adjust medium-wave series pecker (slotted screw on dial pointer) for maximum response. Move pointer to 150 and feed 1500 kc to antenna.

Short-Wave Alignment

Set wave-band switch at short-wave (counter-clockwise) position. Set pointer at 15, feed 15 megacycles to antenna and adjust short-wave oscillator trimmer and then short-wave antenna trimmer for maximum response.

EMERSON RADIO & PHONO. CORP. MODELS AM131, AM169, AM187
 Chassis AM
 Schematic, Voltage, Changes

PRODUCTION CHANGES
 In receivers bearing serial numbers below 1,184,290:

The variable condenser was part number 3CC-275. The dial pointer was part number 4MZ-590.

SIX TUBES, INCLUDING BALLAST TUBE MODELS AM-131, AM-169 and AM-187

Chassis Model AM

Voltage rating 105-125 volts, a.c. or d.c.
 Power consumption 50 watts.
 Frequency ranges 540 to 1,730 kc, and 5.6 to 18.0 megacycles.

Tube Data

The tube complement is as follows:
 1—6A7 pentagrid oscillator-modulator.
 1—6D6 first i-f amplifier.
 1—6Q7 diode detector, a-f amplifier, a.v.c.
 1—25L6 beam power output.
 1—25Z5 dual half-wave rectifier.
 1—2UR-224 ballast tube (R13 on schematic).

NOTE: All metal tubes may be replaced with equivalent octal base glass tubes.

MODELS AM131, AM169, AM187

Chassis AM EMERSON RADIO & PHONO. CORP.
Alignment, Notes, Parts

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a standard dummy antenna (a 5000 ohm resistor) be used as a substitute.
3. The filament dropping resistor (R13 on schematic) is in the metal part of the chassis. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unscrew all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:
 Plate—blue
 Grid—green
 B plus—red
7. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of wiring and achievement of high efficiency on all frequency ranges, the Emerson All-Wave High Fidelity Antenna, Model W-86, is recommended. Instructions for the installation of these antennas are supplied with each kit.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 466 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

ADJUSTMENTS

An oscillator with frequencies of 454, 600, 1428 and 15,000 kc should be used. In addition an output meter should be used across the voice coil or output transformer for observing maximum response. The set's oscillator is higher in frequency than the signal, so no change should be observed on the low frequency side of the signal. Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last method in adjusting trimmers should always be a tightening one, not a loosening one. Always use as weak a test signal as possible during alignment. Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Location of Coils and Trimmer Adjustments

The broadcast antenna coil, the short-wave antenna coil and the 466 kc wave trap are on assembly mounted under the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis. The trimmer closest to the front of the chassis is for the short-wave antenna coil. The central trimmer is for the broadcast antenna coil and the trimmer farthest from the chassis front is for the 466 kc wave trap. The broadcast oscillator and short-wave oscillator coils are wound on one form and mounted on the inside of the rear chassis wall. The trimmers for these coils are accessible through two holes in the rear chassis wall. The set's broadcast oscillator coil, the rear wall is for the short-wave oscillator coil and the right-hand trimmer is for the broadcast oscillator coil. The two i-f transformers are in oblong coil cans located on the top of the chassis. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans. The broadcast series padding condenser is located on the rear wall of the chassis below the 6A7 tube.

i-f Transformer and Wave-Trap Alignment

Turn the set, clockwise to the broadcast position and rotate the variable condenser to the minimum capacity. Feed 15 megacycles through the dummy antenna and adjust the short-wave oscillator trimmer (left-hand screw on rear chassis wall) for minimum response. The variable condenser should be rotated while adjusting the antenna trimmer. (Rotate variable condenser rotor shaft back and forth through a small arc.)

Short-Wave Alignment

Use a dummy antenna (500 ohm resistor) when aligning the short-wave coils. Rotate the wave-band switch counter-clockwise to the short-wave position and set the dial pointer to 15 megacycles. Feed 15 megacycles through the dummy antenna and adjust the short-wave oscillator trimmer (left-hand screw on rear chassis wall) for minimum response. The variable condenser should be rotated while adjusting the antenna trimmer. (Rotate variable condenser rotor shaft back and forth through a small arc.)

Broadcast Alignment

Rotate the wave-band switch to the broadcast position, clockwise, and set the dial pointer at 60. Feed 600 kc through a standard dummy antenna (a 5000 ohm resistor) and adjust the broadcast antenna trimmer (right-hand screw on rear chassis wall) for maximum response. Return pointer to 90, feed 600 kc and readjust the series padding condenser rotating the variable condenser for maximum response.

REPLACEMENT PARTS LIST

Part No.	DESCRIPTION	Price
4CT-299A	Two-band antenna coil	\$1.50
4CT-299B	466 kc second i-f transformer	1.50

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

PRODUCTION CHANGES

OS and OS trimmers were supplied separately and have incorporated as part of the short-wave antenna and detector coil assembly.

ADJUSTMENTS

An oscillator with frequencies of 150, 345, 465, 690, 1000 and 1600 kc should be used. Instructions for adjusting antenna trimmers and oscillator trimmers.

TUBE DATA

The tube complement is as follows: 1-6A5, 1-6X4, 1-6AR5, 1-6BE6, 1-6BE7, 1-6BE8, 1-6BE9, 1-6BE10, 1-6BE11, 1-6BE12, 1-6BE13, 1-6BE14, 1-6BE15, 1-6BE16, 1-6BE17, 1-6BE18, 1-6BE19, 1-6BE20, 1-6BE21, 1-6BE22, 1-6BE23, 1-6BE24, 1-6BE25, 1-6BE26, 1-6BE27, 1-6BE28, 1-6BE29, 1-6BE30, 1-6BE31, 1-6BE32, 1-6BE33, 1-6BE34, 1-6BE35, 1-6BE36, 1-6BE37, 1-6BE38, 1-6BE39, 1-6BE40, 1-6BE41, 1-6BE42, 1-6BE43, 1-6BE44, 1-6BE45, 1-6BE46, 1-6BE47, 1-6BE48, 1-6BE49, 1-6BE50, 1-6BE51, 1-6BE52, 1-6BE53, 1-6BE54, 1-6BE55, 1-6BE56, 1-6BE57, 1-6BE58, 1-6BE59, 1-6BE60, 1-6BE61, 1-6BE62, 1-6BE63, 1-6BE64, 1-6BE65, 1-6BE66, 1-6BE67, 1-6BE68, 1-6BE69, 1-6BE70, 1-6BE71, 1-6BE72, 1-6BE73, 1-6BE74, 1-6BE75, 1-6BE76, 1-6BE77, 1-6BE78, 1-6BE79, 1-6BE80, 1-6BE81, 1-6BE82, 1-6BE83, 1-6BE84, 1-6BE85, 1-6BE86, 1-6BE87, 1-6BE88, 1-6BE89, 1-6BE90, 1-6BE91, 1-6BE92, 1-6BE93, 1-6BE94, 1-6BE95, 1-6BE96, 1-6BE97, 1-6BE98, 1-6BE99, 1-6BE100.

Medium-Wave Alignment

Both pointers on the dial should coincide vertically at 930 kc. For adjustment, the gold pointer may be slipped across the dial.

Long-Wave Alignment

Set the wave-band switch at the long-wave (central) position and the pointer to 160. Feed 160 kc through a standard dummy antenna.

Short-Wave Alignment

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 15, feed 16000 kc to antenna (using a 400 ohm dummy antenna).

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on Always observe the frequency of the signal.

GENERAL NOTES

1. An electrical photograph pick-up may be connected to this receiver for playing records. Connections to the receiver may be made at the "phono" terminal strip which is located on the rear wall of the receiver chassis.

2. The tuning indicator (6G5 tube) is mounted on the table type receiver. It is necessary to remove the speaker from the baffles, in order to remove the tuning indicator tube assembly.

3. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or chassis from cabinet.

4. Always observe the frequency of the signal on all three bands. Images, therefore, should be observed on Always observe the frequency of the signal.

5. One side of the power line is connected to the chassis through the filter chokes L3 (see schematic). Under no condition, the power line should be connected to the chassis through the filter chokes L3 (see schematic).

6. The tuning indicator (6G5 tube) is mounted on the table type receiver. It is necessary to remove the speaker from the baffles, in order to remove the tuning indicator tube assembly.

7. An official alignment is necessary to enable a 6H modification of the receiver. The Emerson Alignment Wave Antenna is supplied in kit form and reduction of noise on all three frequency ranges. Consult the instructions for the installation of this antenna as supplied with each kit.

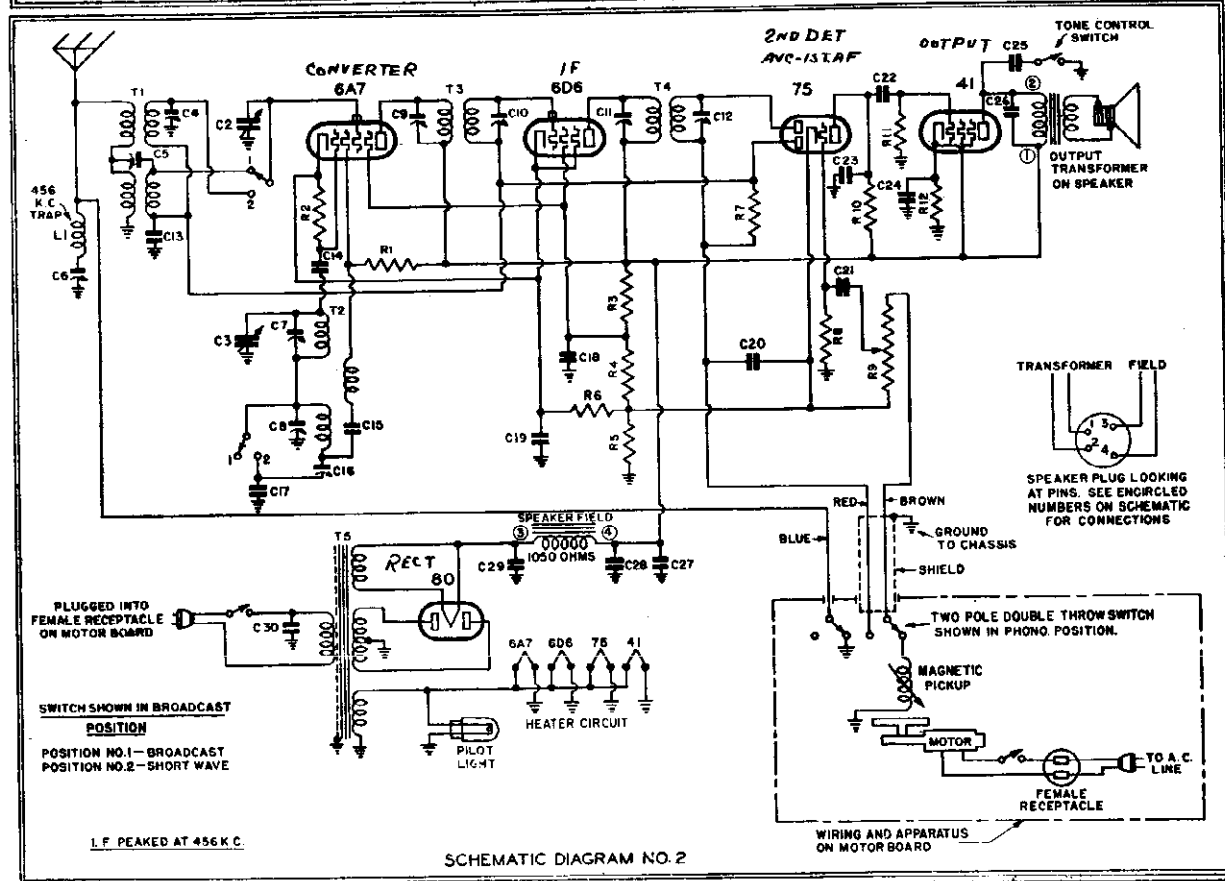

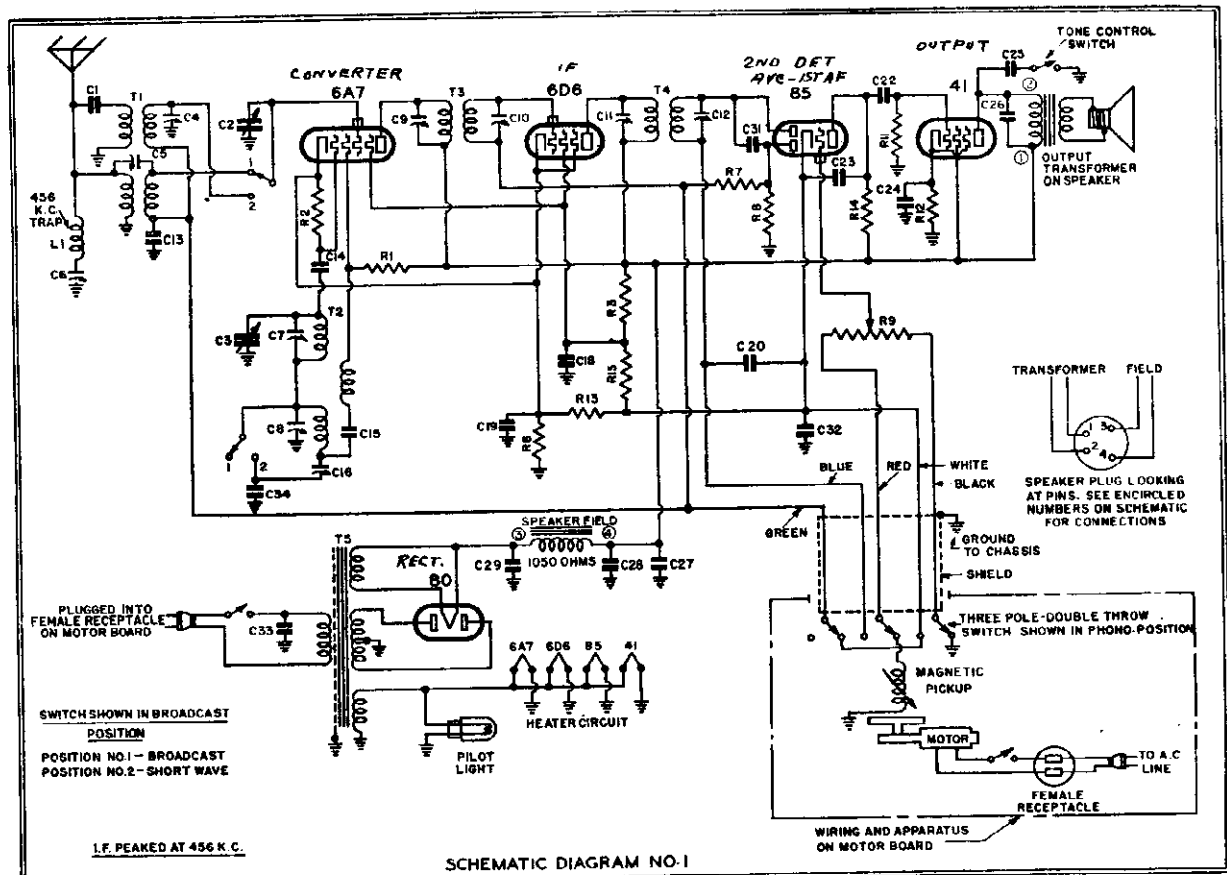

8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 485 kc. If, however, persistent interference from the underwriting station is experienced, it is recommended that the wave-trap be adjusted to reject the station.

9. The receivers for 105-125 volt operation may be easily converted for 210-250 volt operation by substituting ballast tubes part no. 3MR-253 for ballast tubes part no. 3MR-249.

*Item number bracketed in the schematic diagram.
†These condensers are part of coil assemblies and will not be supplied separately.
‡See Production Changes, paragraph 1. **PRICES SUBJECT TO CHANGE WITHOUT NOTICE**

1. Schematic No. 1 applies to receivers bearing serial numbers below 895,962.
2. In receivers bearing serial numbers below 895,962:
a. The two trimmers of the antenna coil, L1, were in parallel from antenna to ground and a 0.00005 mf mica condenser was connected to the antenna coil and the short-wave primary.
b. L17 was an 0.00135 mf mica condenser.

ADJUSTMENTS

An oscillator with frequencies of 456, 604, 1800 and 6040 kc should be used. An antenna coil should be used across the top of the chassis of the oscillator transformer for observing maximum response. If this circuit is to be observed, both the broadcast and short-wave bands must be receiving.

Location of Coils and Trimmer Adjustments

The top of the chassis deck. The second I-F is the one directly behind the variable condenser. The four trimmers are accessible through holes in the top of the chassis.

The 456 kc wave trap is located on top of the chassis deck, in the center near the 6A7 tubes with the screw adjustment accessible through a hole in the top of the chassis.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis in the top of the chassis. The trimmers for these coils are accessible through holes in the top of the chassis.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis in the top of the chassis. The trimmers for these coils are accessible through holes in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis in the top of the chassis.

I-F and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four I-F trimmers for maximum response. (See paragraph 4 under General Notes.)

Short-wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Use a 400 ohm dummy antenna (a 400 ohm resistor is satisfactory) for the oscillator antenna (see) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position, counter-clockwise, and adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 6000 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response. Adjust the antenna trimmer (closest to front beside the variable condenser) for maximum response. Adjust the antenna trimmer (left side of top of chassis). Rotate potentiometer for maximum response. Adjust the broadcast series padder, rotating the variable condenser (rotate the variable condenser shaft, back and forth through a small arc) for maximum response.

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils (A 1000 ohm resistor may be used as a substitute). Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer to 1000 and feed 6040 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response. Adjust the antenna trimmer (right side of chassis). Rotate potentiometer for maximum response. Adjust the broadcast series padder, rotating the variable condenser (rotate the variable condenser shaft, back and forth through a small arc) for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so image should be observed on the low frequency side of the signal.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since this will damage the radio tubes.

2. When replacing the chassis in the cabinet take care to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonics will result.

3. The color coding of the I-F transformer is as follows: Grid—green; Plate—blue; Fil and ground—black.

4. The color coding of the power transformer is as follows: Primary—two black leads; High-voltage secondary—two red leads; 6.3-volt filament secondary—red and yellow lead; 5-volt filament secondary—two yellow leads.

5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave bands are adjustable through holes in the top of the chassis. When replacing this fixed padding capacitor use a condenser which has a capacity within 2% of the specified value.

6. With a few exceptions, the color coding of the general wiring is as follows: Grid—green; Plate—blue; Fil and ground—black; Cathode—white or yellow.

7. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraph station, the wave-trap trimmer may be readjusted until the response from the interfering station is at a minimum.

8. Complete instructions for the installation of the receiver are given in the instruction booklet.

9. The phonograph motor has been adjusted at the factory to the speed of 78 r.p.m. (The speed may be checked by counting the turns per minute of a stroboscope disc and a moon light.) (This stroboscope may be checked by work on moon balls in lighted from a 90 cycle a.c. supply.) To readjust the speed of the motor, part No. B1134, of the speed adjusting screw is located near the turntable shaft.) A clockwise rotation of the screw increases the speed. The speed should be adjusted near the middle of the adjusting range. (The speed of the motor, part No. B1134, may be checked by counting the turns per minute of a stroboscope disc and a moon light.)

10. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

11. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

12. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

13. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

14. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

15. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

16. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

17. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

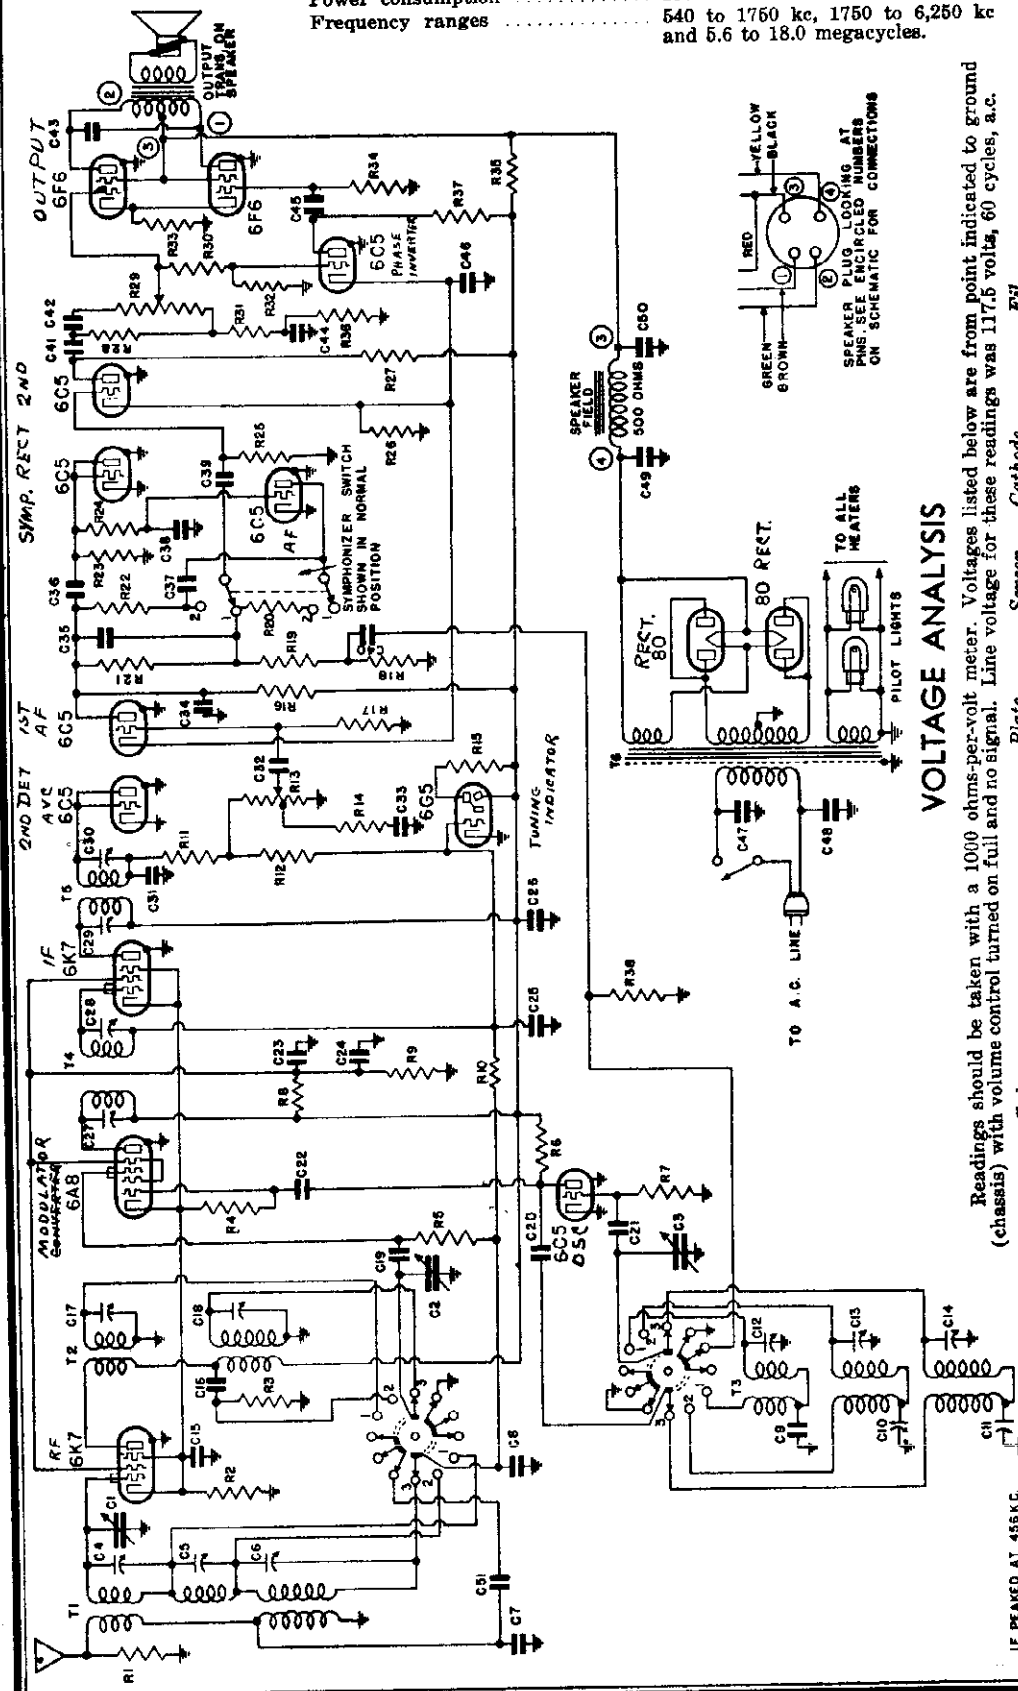

18. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

19. The speed of the motor is adjustable through a hole in the top of the chassis. The speed of the motor is adjustable through a hole in the top of the chassis.

32T-700	30,000 ohm, 1/2 watt carbon resistor	1.00	

ADJUSTMENTS

An oscillator with frequencies of 465, 600, 1800, 3000, 6000 and 16,000 kc should be used.
 An output meter should be used across the voice coil or speaker output transformer for observing maximum response.
 Use a standard dummy antenna for aligning any of the three bands. A 0.002 mf condenser may be used for broad-
 cast for the short-wave band dummy antenna.
 Always use as weak a test signal as possible during alignment.
 Always align the antenna in frequency than the signal on all three bands, as images should be observed on the
 low frequency side of the signal.
 Always choose the minimum capacity peak on oscillator trimmer and maximum capacity peak on antenna trim-
 mer.
 The last motion in adjusting trimmers should always be a tightening one, not a loosening one.
 Never use a trimmer with the outside plate to loose that there is no position on the screw.
 Always align antenna trimmers on the high-frequency signals there is always a tendency for the oscillator to drift,
 due to interlocking. To compensate for this always keep tuning the variable condenser as the trimmer are being ad-
 justed.

Location of Coils and Trimmer Adjustments

The L-I transformers are located on the left-hand side of the top of the chassis. The first L-I transformer is the one
 nearest the rear of the chassis. The four trimmers for the L-I adjustment are available through holes in the top of the
 chassis.
 The antenna coils for the three bands are wound on one form, located on the front wall of the chassis with the
 trimmer coil on the right-hand side. The form is located on the broadcast band, the right-hand trim-
 mer is for the short-wave band and the central trimmer is for the police band.
 The L-I interstage coils are also wound on one form and mounted underneath the chassis on the right-hand side of
 the variable condenser. The trimmers are accessible through holes in the top of the chassis. The trimmer clear to the
 coil. The trimmer clear to the coil. The trimmer clear to the coil. The trimmer clear to the coil. The trimmer clear to the coil.
 The trimmer coils are wound on one form and mounted underneath the chassis directly behind the L-I interstage
 coil. The trimmers are accessible through holes in the top of the chassis. The trimmer clear to the variable condenser.
 for the broadcast band, the trimmer farthest from the variable is for the short-wave band and the central trimmer is
 for the police band.
 The oscillator series paddler for the broadcast and police bands are mounted underneath the chassis near the cap-
 acitor coils. The adjusting screws are available through holes in the top of the chassis. The paddler nearest the front of
 chassis is for the broadcast band. The paddler for the short-wave band is a .0008 fixed mica condenser. If this condenser
 is to be replaced use a condenser with 1% of that specified.
 The antenna coils are wound on one form and mounted underneath the chassis directly behind the L-I interstage
 position. Feed 450 kc to the grid cap of the 6AG tube through a .02 mf condenser and adjust the four L-I trimmers for
 maximum response. (Do not remove the grid clip from the tubes).
 The three bands should be aligned in the following order: Short-wave band first, police-band second, and broadcast-band last.

Short-Wave Alignment

Both pointers on the dial should coincide vertically at 890 kc. (For adjustment the gold pointer may be slipped
 around on its shaft).
 Set the wave-band switch at the short-wave (counter-clockwise) position. Move the dial pointer to 15 and feed
 18,000 kc to the antenna (using a dummy antenna) and adjust the short-wave oscillator trimmer for maximum
 response. If the antenna is not being used, adjust the short-wave oscillator trimmer for maximum
 response. If two peaks are obtained choose the maximum response peak.

Police Alignment

Set the wave-band switch at the police-band (central) position and the dial pointer at 1.8. Feed 1,800 kc to the an-
 tenna (using a dummy antenna) and adjust the oscillator trimmer for maximum response. Move the
 dial pointer to 6.0 and adjust the oscillator trimmer for maximum response. Move the
 dial pointer to 1.8, feed 1,800 kc to the antenna and adjust the oscillator trimmer for maximum response. Move
 the dial pointer to 6.0 and adjust the oscillator trimmer for maximum response. Return to 1.8, feed 1,800 kc to the antenna
 and check alignment. If readjustment is necessary return to 1,800 kc and repeat
 entire procedure.

Broadcast Alignment

Set the wave-band switch at the broadcast (clockwise) position, and the dial pointer at 60. Feed 600 kc to the an-
 tenna (using a dummy antenna) and adjust the broadcast-band series paddler for maximum response. Move
 the dial pointer to 600 kc and adjust the oscillator trimmer for maximum response. Move the
 dial pointer to 1.8, feed 1,800 kc to the antenna and adjust the oscillator trimmer for maximum response. Move
 the dial pointer to 600 kc and adjust the oscillator trimmer for maximum response. Return to 1,800 kc and repeat
 entire procedure.

GENERAL NOTES

1. The power source should never be turned on with either the speaker plug or the 69K tubes out of their sockets, since the
 rapid rise in rectifier voltage would damage the electrolytic condensers.
2. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary
 to remove either the dial or chassis from cabinet.
3. In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not seat freely, and do not
 tighten screws so much that dial will not seat properly. To insure that chassis is seated properly, the cabinet
 front panel. If these precautions are not observed the receiver may become microphonic.
4. The color coding of the power transformer leads is as follows:
 Primary—two black leads
 High voltage sec.—two red leads
 High voltage secondary center tap—red and yellow lead
 by sec.—two heavy green leads
 by sec.—two heavy yellow leads
5. The tuning indicator (665 tube) is mounted in the cabinet above the dial. The color coding of the tuning indicator
 tube cable is as follows:
 Shield—black
 Shield—white
 Grid—green
 Wad—orange
6. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. The Emerson All-
 Wave Antenna is especially designed for high efficiency and reduction of noise on all frequency ranges. Complete in-
 structions for the installation of this antenna are supplied with each kit.

*Item number locates the article on the schematic diagram.
 †These trimmer condensers are part of the coil assemblies and can not be supplied separately.

GENERAL NOTES

- As electrical photograph pick-up may be connected to this receiver for playing records. Connections to the receiver may be made at the "Phono" terminal strip which is located on the rear wall of the receiver chassis. A double-pole, double-throw switch is necessary in addition to the photograph pick-up and motor. The receiver volume control may be used to control the photograph pick-up and terminal strip so that in the photograph position the switch should short terminals 1 and 3 and at the same time connect the high side of the pick-up to a lead from terminal 2. (The ground side of the pick-up may be permanently wired to terminal 1.) When the switch is in the radio position terminals 2 and 3 should be shorted together and the pick-up disconnected from terminal 1. A matching input transformer must be used if the pick-up is of the impedance matching type. (See schematic diagram.)
- The receiver should never be turned on with the speaker plug out of its socket, since the rapid rise in rectifier voltage would damage the electrolytic condenser.
- Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or cabinet as the bulbs do not touch mounting screws so much that chassis will not float freely, and do not allow any part of the dial assembly to touch the cabinet. Do not push control knobs on so far that they touch the cabinet front panel. If these precautions are not observed the receiver may become microphonic.
- One side of the power line is connected to the chassis. Under no condition, therefore, should a ground wire be allowed to connect to the chassis.
- A sufficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of W-2L, or the Emerson All-Wave Antenna System, Model W-38, are recommended. Complete instructions for the installation of these antennas are supplied with each set.
- When a weak station signal is received, antenna signal rejection at 455 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until this response from the interfering station is at a minimum.
- The receiver for 105-125 volt operation may be easily converted for 210-250 volt operation by substituting ballast tubes part no. 3MR-253 for ballast tubes part no. 3MZ-419.

ADJUSTMENTS

An oscillator with frequencies of 150, 345, 455, 600, 1600 and 16000 kc should be used. Use a standard dummy antenna for aligning any of the three bands. A .0002 mf condenser may be used for the medium-wave band and the on-wave band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Always use as weak a test signal as possible when aligning the receiver.

Always align the oscillator at a higher frequency than the signal on all three bands. In cases, therefore, should be observed on the low-frequency side of the signal.

Always choose the minimum capacity peak on oscillator trimmer and maximum capacity peaks on antenna and I-F trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate of the high-frequency signal there in usually a tendency for the oscillator to drift, or re-aligning antenna trimmers on this always keep re-tuning the variable condenser as you align.

MODEL AG - 151

Chassis Model AG
Voltage rating 105-125 volts, a.c. or d.c. (with ballast tubes part no. 3MZ-419).
210-250 volts, a.c. or d.c. (with ballast tubes part no. 3MR-253).

TUBE DATA

- 6X4—R-F amplifier (on tuner unit)
- 6D6—I-F amplifier
- 6D7—Second detector, a.v.c., and A-F amplifier
- 6C7—A-F amplifier
- 2-257G—Push-pull pentode output
- 2-3MZ-419—Ballast tubes for 105-125 volt operation
- 2-3MR-253—Ballast tubes for 210-250 volt operation

Medium-Wave Alignment

Both pointers on the dial should coincide vertically at 690 kc. For adjustment, the gold pointer may be slipped around the dial until it coincides with the antenna terminal and adjust the long-wave series paddler for maximum response. Move the antenna terminal and adjust the long-wave series paddler for maximum response. Move the pointer to 160 kc and readjust the long-wave series paddler for maximum response. Then adjust detector and antenna trimmers. Reset the pointer to 60 kc, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator paddler for maximum response. Return to 1500 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Long-Wave Alignment

Set the wave-band switch at the long-wave (center) position and the pointer to 150. Feed 150 kc through a standard dummy antenna and adjust the long-wave series paddler for maximum response. Move the antenna terminal and adjust the long-wave series paddler for maximum response. Return to 345 kc and readjust all three trimmers. Return again to 150 and check the alignment. Repeat the entire procedure until no appreciable re-adjustment is required.

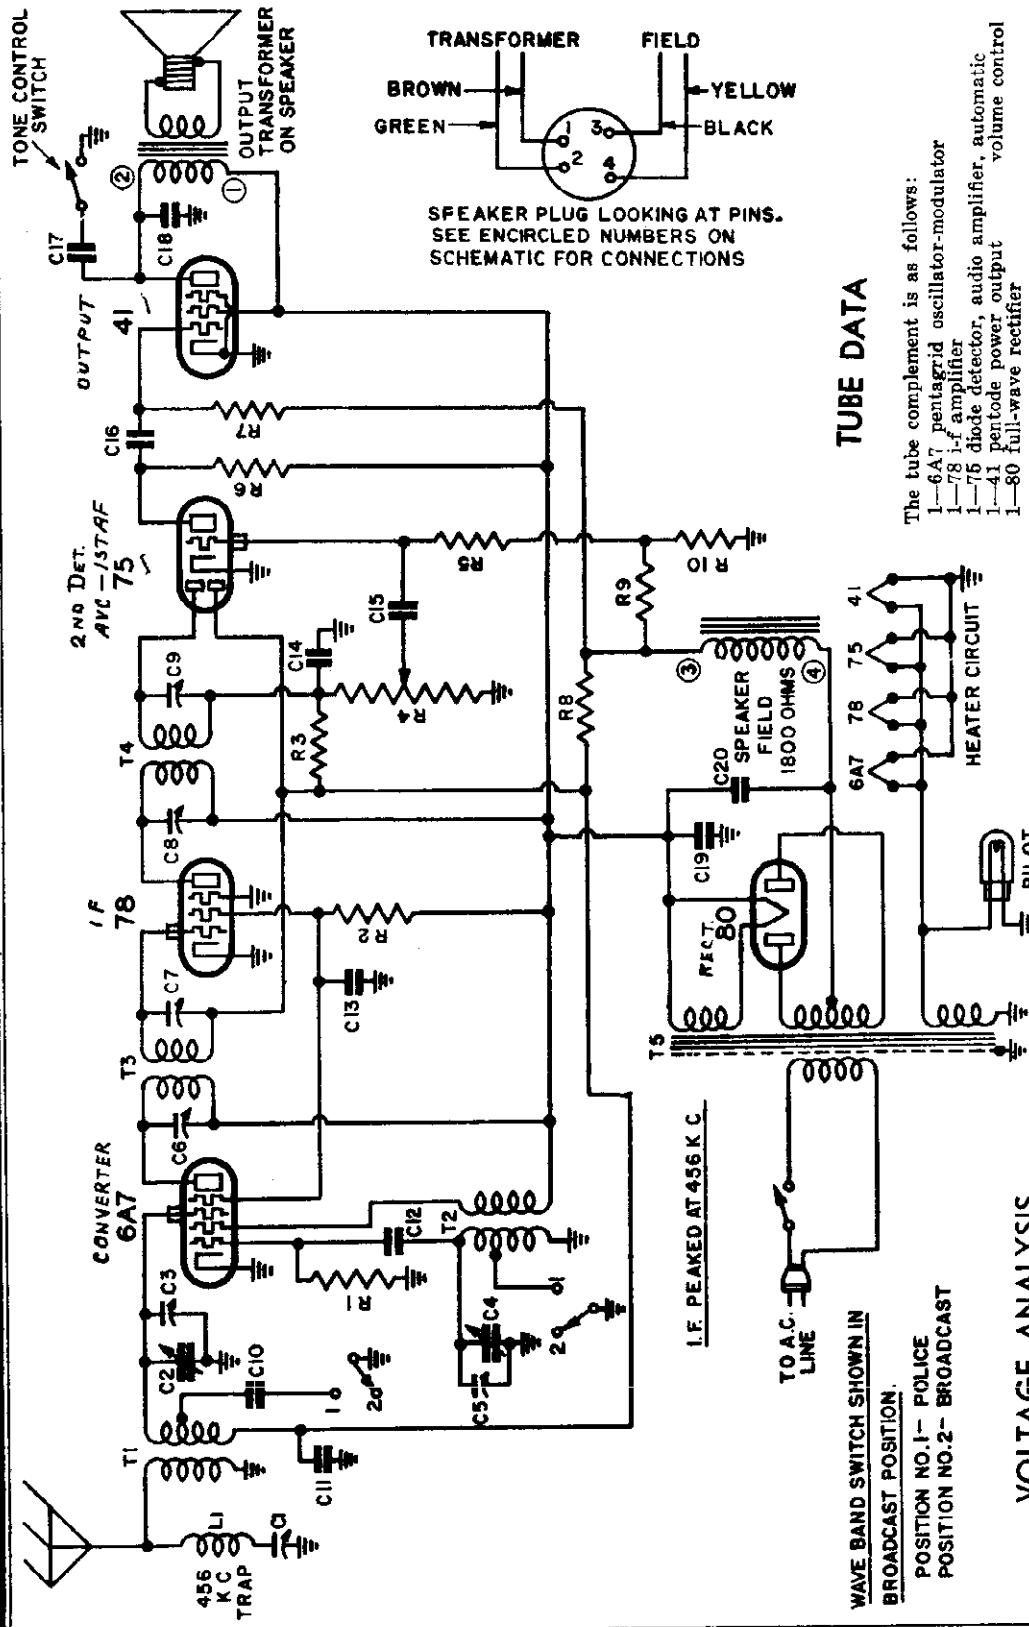

Short-Wave Alignment

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 15. Feed 16000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the detector and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

*Then number locates the article on the schematic diagram.
†These trimmers cannot be supplied separately.

*Item number locates the article on the schematic diagram.
†These trimmers are part of coil assemblies and can not be supplied separately.
‡These trimmers are part of variable condenser and can not be supplied separately.

ADJUSTMENTS

An oscillator with frequencies of 456 and 1400 kc is required.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f transformer is the one directly behind the 5A7 tube. The trimmers for the two i-f transformers are available through holes in the top of the case.

The trimmers for the antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

The 456 kc wave-trap is mounted on the rear chassis wall directly beneath the wave-band switch. The trimmers for the 456 kc wave-trap is mounted on the coil and is accessible from the bottom of the chassis.

i-f and Wave-Trap Alignment

Rotate the wave-band switch (located on the rear wall of the chassis) to the broadcast position, clockwise, and swing the variable condenser to the maximum capacity position. Feed 456 kc to the grid-cap of the 6A7 tube and adjust the trimmer for maximum response. Feed 456 kc through a dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust the wave-trap trimmer for maximum response. (See General Notes, paragraph No. 1.)

Broadcast Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

GENERAL NOTES

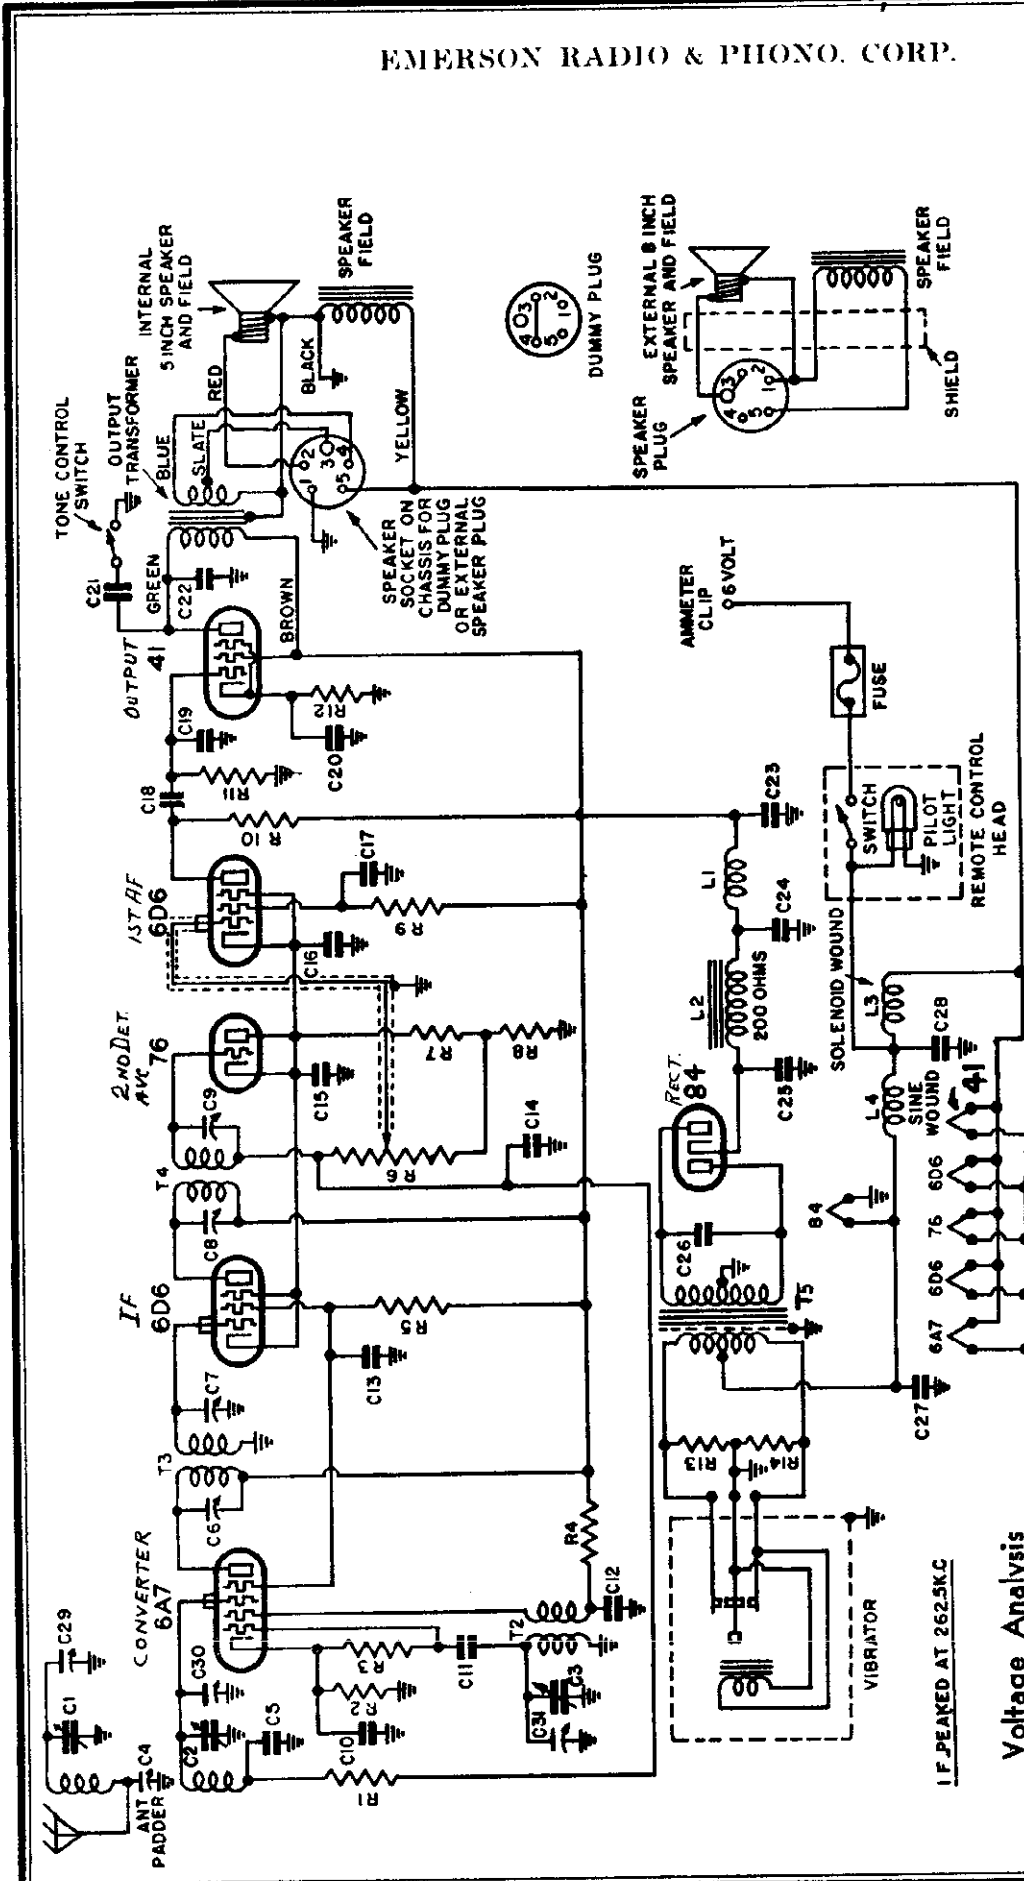

- The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
- The receiver should never be turned on with either the speaker plug or the 41 tube out of their sockets, since the rapid rise in rectifier voltage would damage the electrolytic condensers.
- The pilot light may be replaced by removing the snap-on socket from the dial and unscrewing the bulb. It is not necessary to remove either the dial or chassis from the cabinet.
- The color coding of the leads of the i-f transformers, is as follows:
Grid—green
Grid return—black
Plate—blue
B plus—red
- The color coding of the power transformer leads is as follows:
Primary—two green leads
6.3 v. sec.—two heavy blue leads
High voltage sec.—two black leads
5 v. sec.—two heavy red leads
High voltage sec. center tap—yellow
- With a few exceptions, the color coding of the general wiring is as follows:
Plate and cathode—white or yellow
Grid—blue
B plus—red
Filament and ground—black
- An efficient antenna system (aerial) is necessary to enable a full realization of the merits of the receiver. The Emerson All-Wave Antenna is especially designed for high efficiency and reduction of noise on all three frequency ranges. Complete instructions for the installation of this antenna are supplied with each kit.

PRODUCTION CHANGES

On early receivers the oscillator coil was part number 3RT-319. When replacing this coil with the new coil, part number 3RT-319A, it will be necessary to remove the short length of shielding over the white lead (lead from wave-band switch to tap on coil).

EMERSON RADIO & PHONO. CORP.

MODEL U154
Chassis U
Schematic, Voltage

All voltages should be measured with a 1000 ohms-per-volt meter. Voltages measured from the point indicated to ground (chassis) with no signal and volume control turned on full. Readings taken with battery voltage of 6.3 volts. Voltage across heaters—6.0. Voltage across speaker field—6.0.

Voltage Analysis

EMERSON RADIO & PHONO. CORP.

Tube Data

The tube complement is as follows:

- 1—6A7 pentagrid oscillator-modulator
- 1—6D6 i-f amplifier (in corner of chassis)
- 1—76 diode detector, a.v.c.
- 1—6D6 a-f amplifier
- 1—41 power output pentode
- 1—84 full-wave thermionic rectifier
- 1 primary type vibrator.

The function of the vibrator is to convert the direct current from the battery into alternating current to actuate the power transformer. The stepped-up voltage is then rectified into direct current by the 84 tube for use as plate supply.

ALIGNMENT PROCEDURE

The receiver was carefully adjusted and tested at the factory, and should reach the customer in perfect condition. Under no circumstances should these adjustments be disturbed unless it is absolutely necessary, as in the repairing of a damaged set. This should be done by an experienced auto radio service man only.

I-f Alignment

To align the intermediate frequency transformers, use a good modulated oscillator set for 262.5 kc. Rotate the variable condenser to the minimum capacity position, turn the volume control on full and ground the antenna to the chassis.

Connect the test oscillator lead, through a paper condenser (.02 mf or larger), to the grid cap of the 6A7 tube. Do not remove the grid clip from the tube. Connect an output meter across the primary of the speaker transformer or across the voice coil. Using the *smallest output* from the test oscillator that will give a definite reading on the meter, adjust the two i-f transformers for maximum response. Use a non-metallic screw driver if possible.

Radio Frequency and Oscillator Alignment

Connect the test oscillator lead through a standard dummy antenna (a .0002 mf condenser may be substituted) to the antenna connector of the receiver. Rotate the variable condenser to the minimum capacity position. Feed 1530 kc and adjust the oscillator trimmer (earlier) on the variable condenser for maximum response. Set the test oscillator to some frequency near 1400 kc and swing the variable until this signal is heard. Adjust the two r-f trimmers (front and rear) on the variable condenser for maximum response. Set the test oscillator for 600 kc and swing the variable until this signal is heard. Adjust the antenna padder (on chassis wall below the variable condenser) for maximum response. Reset the test oscillator to some frequency near 1400 kc and readjust the two r-f trimmers for maximum response. Reduce the output of the test oscillator and repeat this adjustment.

Note: The antenna padder should be readjusted when the receiver is installed in the car. (See paragraph (g) under installation instructions.)

Suppression of Ignition Interference

If, when the receiver is in operation, and the motor is running, the ignition interference is excessive the following suggestions should help to reduce it to a satisfactory level.

- By-pass dome light wire at instrument panel with a 1/2 mf condenser.
 - By-pass the low tension lead to the ignition coil with a 1/2 mf condenser.
 - Shield high tension lead from coil and ground to fire wall.
 - Shield low tension leads to ignition coil.
 - Try grounding antenna shield at various points, and also try leaving shield ungrounded, except at point where it is automatically grounded at receiver by means of the metal connector. Move all adjacent wiring slightly and note if it may be coupling to the battery lead to receiver.
 - Bond steering column to fire wall.
 - Try bonding exhaust pipe, particularly if interference is increased with passengers in car.
 - Bond metal cables or pipes coming through fire wall, connecting them to the fire wall. If car has wooden floor boards, place a screen underneath floor mat and note if interference is decreased, particularly with passengers in car.
 - Check antenna wiring, making sure it is shielded completely.
 - Try bonding windshield wiper pipe.
 - Check ignition system for defects.
 - When condensers are used for by-passing ignition interference, their leads should be as short as possible, since often a condenser with leads a fraction of an inch long will be very effective in places where the same condenser with longer leads would be useless.
- Note:** It is recommended that the charging rate of the car generator be increased slightly to compensate for the added drain of the receiver.

General Notes

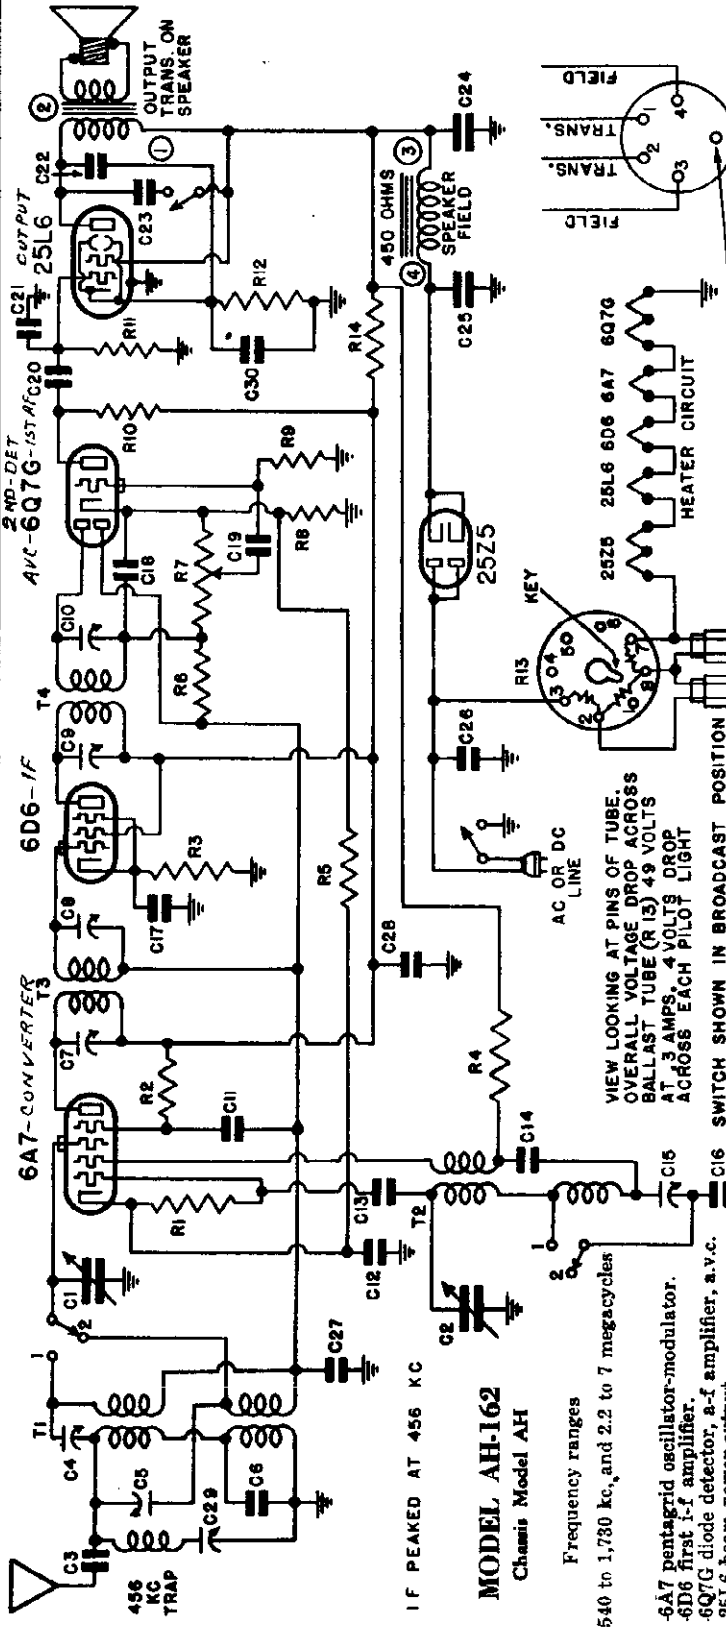

1. To remove the chassis from the case it will be necessary to unsolder the speaker leads.
2. It should be noted that one side of the speaker field is grounded to the speaker frame.
3. A 10 ampere fuse is located in a small tubular holder in the battery lead. The fuse is intended to protect the receiver and in no case should one larger than 10 amperes be used.

MODEL AH162

Chassis AH

Voltage, Alignment

Notes

EMERSON RADIO & PHONO. CORP.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	100	55	2.0	77	6.3
6D6	100	100	3.3	—	6.3
6Q7G	38	—	1.0	—	6.3
25L6	96	108	6.7	—	25.0

Voltage at 25Z5 cathode—130 volts.

Voltage across speaker field—28 volts.

Voltage drop across ballast tube (pins Nos. 3, 7)—49 volts.

Voltage drop across each pilot light section (pins Nos. 2, 8 and Nos. 8, 7)—4 volts

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R13 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The color coding of the i-f transformer leads is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red
6. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.

In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.
7. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

An oscillator with frequencies of 456, 600, 1600 and 6,000 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response. If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a standard dummy antenna for aligning either of the bands. A .0002 mf condenser may be used for the broadcast band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands and the 456 kc wave trap are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The central trimmer is the broadcast antenna trimmer. The trimmer nearest the rear of the chassis is the 456 kc wave trap.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc, through a 0.02 mf paper condenser, to the grid cap of the 6A7 tube (do not remove the grid clip from the tube). Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna through a standard dummy antenna and adjust the wave-trap trimmer for *minimum* response. (See General Notes.)

Short-Wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Rotate the wave-band switch to the short-wave (counter-clockwise) position, and set the dial pointer exactly at 6 megacycles. Feed 6,000 kc to the antenna and adjust the short-wave oscillator trimmer for maximum response, and then adjust the short-wave antenna trimmer for maximum response. Be very careful to choose the minimum capacity peak on the oscillator trimmer.

Broadcast Alignment

Rotate the wave-band switch to the broadcast position (clockwise) and set the dial pointer at 60. Feed 600 kc through a standard dummy antenna. Adjust the broadcast series padding condenser for maximum response. Move pointer to 160, feed 1600 kc and adjust the broadcast oscillator trimmer for maximum response and then adjust the broadcast antenna trimmer for maximum response. Return pointer to 60, feed 600 kc and readjust the series padding condenser rocking the variable condenser for maximum response.

In receivers bearing serial numbers below 1,121,800, A. C19 was connected from the plate of the 25L6 tube to B plus.

List Price as of April 14, 1937 (Subject to change without notice)

MODEL AE163

Chassis AE

Voltage, Alignment

Notes

EMERSON RADIO & PHONO. CORP.

GENERAL NOTES

1. If replacements are made or the wiring distributed in the r-f section of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R12—see schematic) is in a special metal tube at back of the chassis. This tube will, therefore, become quite hot under normal operating conditions. For voltage drop see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug for correct polarity.
5. The color coding of the i-f transformer leads is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red

Tube Data

The tube complement is as follows:

- 1—6A7 pentagrid oscillator-modulator.
- 1—6D6 first i-f amplifier.
- 1—6Q7G diode detector, audio amplifier, automatic volume control.
- 1—25L6 pentode power output.
- 1—25Z5 dual half-wave rectifier.
- 1—3CR-241 ballast tube.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Osc. Plate	Cathode	Fil.
6A7	100	50	100	2.4	6.3
6D6	100	100	—	3.8	6.3
6Q7G	45	—	—	1.1	6.3
25L6	95	100	—	6.4	25.0

Voltage across speaker field—30 volts.

Overall voltage drop across ballast tube, (See R12, schematic)—49 volts at .3 amps.

Voltage drop across the pilot light section of ballast tube—4 volts, a.c.

ADJUSTMENTS

An oscillator with frequencies of 456 kc and 1500 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Always use as weak a test signal as possible.

Location of I-f Transformers and Trimmers

The first i-f transformer, part number 4ET-350, is in an oblong coil can located on the top of the chassis directly behind the 6A7 tube. The two trimmers for this i-f are accessible through holes in the top of the coil can.

The second i-f transformer, part number 4ET-351 is in an oblong coil can located on top of the chassis directly behind the speaker. The two trimmers for this i-f are accessible through holes in the top of the coil can.

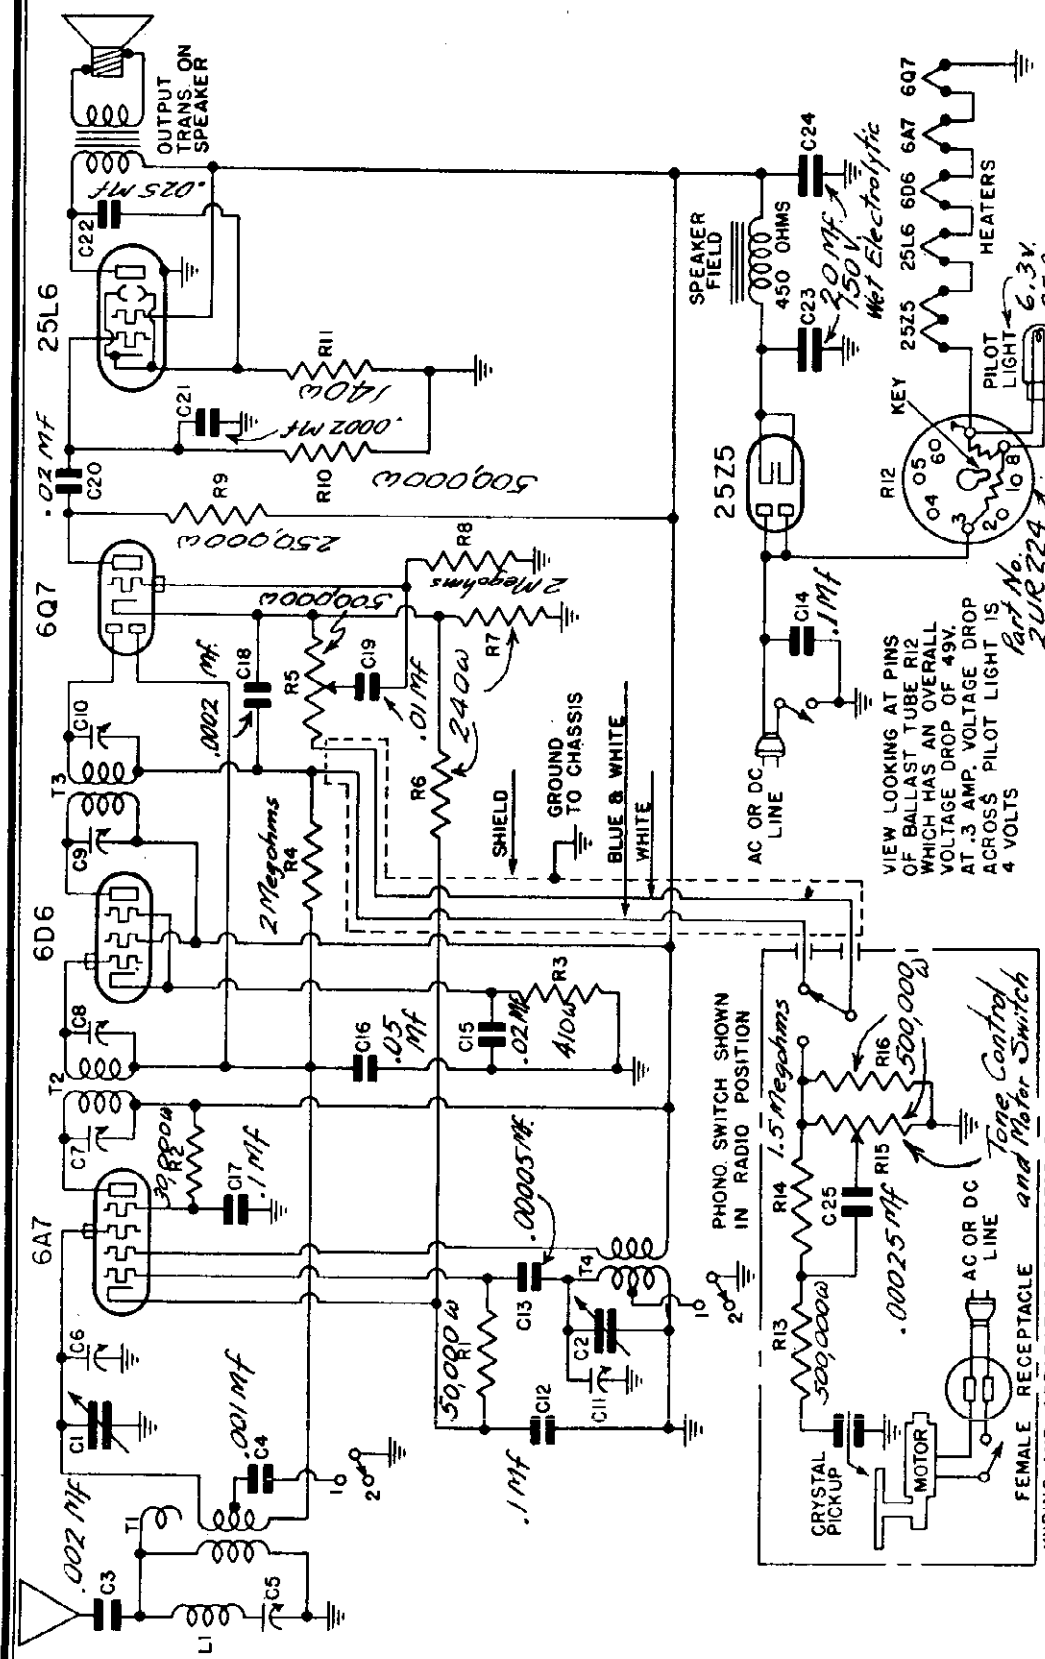

The oscillator and antenna trimmers are located on the variable condenser. The oscillator trimmer is on the rear section of the variable condenser and the antenna trimmer is on the front section of the variable condenser.

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 456 kc to the grid cap of the 6A7 tube, through a .02 mf paper condenser.
3. Adjust the i-f trimmers, repeating for maximum response.
4. Set the dial pointer to 1500 and feed 1500 kc to the antenna lead through a standard dummy antenna. (A .0001 mf mica condenser may be used as a substitute.)
5. Adjust the oscillator trimmer (on rear section of variable condenser) for maximum response.
6. Adjust the antenna trimmer (on front section of variable condenser) for maximum response.

MODEL AL164
Chassis AL
Notes, Alignment

EMERSON RADIO & PHONO. CORP.

Model AL-164

CHASSIS MODEL AL

Voltage rating 105 to 125 volts a.c. or d.c.
Power consumption 43 watts for receiver and 26 watts for motor
Frequency range 540 to 1580 kc (See paragraph 11 in General Notes below).

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R12 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder its leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red
7. The receiver is shipped with an attached antenna wire. In some locations near powerful local stations the addition of a very large antenna may be detrimental to reception, because of the resulting interference. The Emerson Flexible Mast Antenna, Model W-32, has been especially designed for Emerson receivers, featuring compactness and portability while at the same time retaining a high efficiency from the standpoint of performance. Since it functions as an outside antenna the Flexible Mast will substantially improve the receiver performance. Where the Flexible Mast is installed permanently, it is urgently recommended that the receiver antenna wire be cut. Leave just enough of this wire to reach from the receiver to the window strip connector. Instructions for the installation of this compact and efficient outside antenna are supplied with each kit.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
9. The phonograph motor has been adjusted at the factory, to turn at a speed of 78 r.p.m. The speed may be checked by counting the turns per minute or by using a stroboscope disc and a neon light (the stroboscope method will only work when the neon bulb is lighted from a 60 cycle a.c. supply).
10. An a.c.-d.c. switch is provided to switch the motor for a.c. or d.c. power supply. It is important that this switch be in the proper position for the power supply available.
11. The receiver in this combination is designed to cover two frequency ranges, but since it is represented as a single band receiver only, the short-wave band, although available, may be ignored.

ADJUSTMENTS

An oscillator with frequencies of 456, 600 and 1400 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a .0001 mf mica condenser as a dummy antenna during alignment.

Location of Coils and Trimmer Adjustments

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The 456 kc wave-trap is mounted on the right side of the front chassis wall. Its trimmer is accessible at the bottom of the chassis.

The antenna coils for the broadcast and police bands are wound on one form and are mounted underneath the chassis deck below the variable condenser.

The oscillator coils for the broadcast and police bands are wound on one form and are mounted on the rear wall of the chassis deck near the variable condenser.

The trimmers for the broadcast antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

I-f Transformer and Wave-Trap Alignment

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer for *minimum* response.

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a .0001 mf condenser to the antenna lead and adjust first the oscillator trimmer on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

VOLTAGE ANALYSIS

Readings should be taken with a 1,000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. The line voltage for these readings was 117.5 volts, 60 cycles a.c.

Tube	Plate	Screen	Osc. Plate	Cathode	Fil.
6A7 osc.-mod.	244	62	118	0	6.3 a.c.
6D6 i-f amp.	244	85	—	0	6.3 a.c.
76 detector a.v.c.	0	—	—	0	6.3 a.c.
76 a-f amp.	85	—	—	0	6.3 a.c.
41 output	226	244	—	0	6.3 a.c.

Voltage across speaker field—65.

Voltage at 80 filament to B minus (center-tap of high-voltage winding on power transformer)—925. The grid bias for all the tubes is developed across the resistors R9 and R11 (see schematic). The total voltage measured across R9 and R11 should be 15 volts, and is the bias for the 41 tube. The voltage measured across R9 should be 5 volts. To check the bias on the 6A7 and 6D6 tubes, measure the values of resistors R6, R7 and R8 (see schematic).

- The tube complement is as follows:
- 1—6A7, pentagrid oscillator-modulator.
 - 1—6D6, i-f amplifier.
 - 1—76, diode detector and a.v.c. (behind second i-f transformer).
 - 1—76, audio amplifier.
 - 1—41, pentode power output.
 - 1—80, full-wave rectifier.

Voltage rating 105-125 volts, 60 cycle a.c.
Power consumption 55 watts
Frequency ranges 540 to 1730 kc and 5.6 to 18 megacycles

PRODUCTION CHANGES

- Model AR-174 receivers differ from the schematic diagram as follows:
- a. C27 is a 12 mf, 450 volt dry electrolytic condenser, part no. 3LC-314.
 - b. C28 is a 24 mf, 400 volt dry electrolytic condenser, part no. 3ZC-341.
 - c. A .25 mf, 200 volt condenser is connected from the screen-grid of the 6D6 i-f amplifier to ground.

In receivers bearing serial numbers below 1,200,100:
a. C1 and C2 was a two-gang variable condenser, part no. 4HC-343B and the dial face used with this condenser was part no. 4RZ-580.

Automatic Dial Notes

AUTOMATIC DIAL Models AT-170, AT-172 and AT-181

CHASSIS AR - SEE INDEX FOR SCHEMATIC

Automatic Dial Tuning

Insert the line plug into the electric outlet. Turn the receiver on by rotating the volume control knob clockwise until the switch is heard to click. Wait about a minute for the tubes to warm up.

Be sure the wave-band switch is in the broadcast position, clockwise.

(Complete information relative to the pre-setting of the Automatic Dial appears on pages 6 to 7 inclusive in this booklet.)

Tuning with the Automatic Dial is very similar to dialing a telephone except that only one turn of the dial is necessary. Merely push in the button bearing the call letters of the desired station, and, keeping the button pressed in firmly, rotate the dial until it stops with the button near the top. The button may then be released. This procedure automatically tunes in the desired station.

The illustrations, Fig. 1, indicate the proper rotation of the dial for a particular button. Note that the button must always stop near the top of the disc. If the button for the desired station is already at the top, rotate the dial in either direction about a quarter turn and then push the button in and rotate the dial back again until it stops with this button near the top.

Broadcast Reception

Broadcast stations may be tuned in the regular manner by means of the station selector knob on the front of the cabinet.

STATION PRE-SETTING OF AUTOMATIC DIAL

The bakelite front plate for the dial will be found in the knob envelope. This plate is to be assembled after following the procedure described below. Eight cards of station call letter tabs for the buttons are in a separate envelope packed with the receiver.

The illustrations at the right, Fig. 2 and Fig. 3, show the major parts of the automatic dial. Ten buttons are supplied with each dial. Note that there are eleven button holes in the circular housing. One of these button holes is not to be used. (See Fig. 3). Each of the buttons may be set for a particular station. The stations chosen should be the popular local broadcast stations. The dial cannot be used for automatic tuning of short-wave stations. Each button is adjustable in that it can be rotated in its hole in the housing. This rotation is the means of adjustment for any particular station.

First turn the receiver on. The adjustments should be made with the receiver warmed up. Of the possible ten selected local stations choose five of the more desirable and determine their frequencies. Station frequencies will usually be found listed in newspapers. The station with the lowest frequency of the first five chosen should be adjusted first. Compare the frequency of this station with the frequency markings on the tab inserts in the buttons. The station frequency will be between the frequency limits marked on one of the buttons and that button should be adjusted for that particular station.

The following procedure should be observed in adjusting the buttons:

1. Do not remove the thin metal disc which holds the buttons in the housing until this entire procedure is completely finished. Merely loosen the face nut slightly and rotate the disc until its semi-circular notch falls below the first button to be adjusted. See Fig. 2. (When rotating this disc it is necessary to successively hold each button in place with a finger as the notch in the disc moves past these buttons.) Tighten the face nut again to prevent the disc from falling off. Take out this button and remove the celluloid cap and tab insert by prying with a sharp instrument at the large notch on the side of the button.

Tune in the desired station by means of the selector knob on the front of the cabinet.

3. The large notch on the side of the button will indicate the position of the stop pin on the back of the button, see Fig. 4. The tip portion of the stop pin in this drawing is the part that stops against the floating vane. This tip portion in stopping against the vane is the action that locates the station once the button is adjusted, see Fig. 5. The vane is visible between the edge of the button housing and the edge of the hole in the cabinet, see Fig. 3.

4. With the station tuned in and without moving the circular housing partially insert the button, lining up the tip portion of the stop pin by eye with the center of the floating vane, and then push the button in, engaging the teeth. See Fig. 6. The center joint of the veneer on the cabinet may be used to assist in this lining up since the joint is approximately at the center of the floating vane.

Hold the button in and rotate the thin metal disc a small fraction of a turn, just enough so that it holds the button in place.

It is important that when the stop pin is lined up it is either horizontal or pointing at some angle away from the hub of the housing. This precaution may be observed by locating the large notch of the button (which is in line with the tip of the stop pin) outside the dotted circle through the buttons as shown in Fig. 3.

5. To check if the button has been properly adjusted rotate the entire housing first in clockwise direction so that the button stop pin is clear of the floating vane. Push the button all the way in with a finger and rotate the housing so that the pin travels toward and stops against the floating vane. The desired station should then be heard. Repeat this procedure on the counter-clockwise side of the vane. The station should again be heard.

6. If the station tunes in perfectly on each side of the vane no further adjustment is necessary. If it does not tune in perfectly, further adjustment should be made by carefully pulling out the button and rotating it one notch in the housing in the direction which will bring in the station more accurately. Check the tuning again by following the procedure outlined in paragraph No. 5. Find the station call letters for this button on one of the cards supplied. Remove the tab from the card and insert in the button by pressing in firmly. Replace the clear celluloid cap over the call letter tab, snapping it firmly in place.

7. Adjust four buttons for the other four selected stations following the procedure outlined above. In adjusting these buttons care should be taken, when rotating the thin metal disc, to keep the other buttons from falling.

8. The remaining buttons, five in number, may be adjusted for any other local stations easily obtainable, or left in reserve for future settings.

9. After the buttons are all adjusted the thin metal disc should be removed carefully by unscrewing the face nut and replaced by the bakelite front plate. Be very careful in removing the thin metal disc that the buttons do not spring out from the housing. The cabinet should be tilted or placed on its back, when placing the bakelite plate on the dial, to make sure that the buttons do not fall out.

Check carefully the drawings in Fig. 3 and Fig. 7 for aligning the bakelite front plate with the circular housing.

The plate must fit in easily and snugly. Care should be taken not to damage the locating pins on the back of the front plate.

The following additional precautions must be observed when adjusting the buttons:

The long pin buttons, when adjusted, should have the long length of the pin nearly horizontal. If these long pins, after the button is adjusted, interfere with any other part of the mechanism when the housing is rotated the buttons cannot be used in these holes.

If no special use is found for the two long pin buttons it is preferable to insert these in unused holes with the pins pointing directly toward the hub of the housing.

When loosening the thin metal disc be sure the face nut is unscrewed only enough to allow the disc to turn. During adjustments check this nut frequently to make sure it is in no danger of falling off. It cannot be emphasized too strongly that the utmost care must be taken to prevent this metal disc or the bakelite front plate from falling off and allowing the adjusted buttons to spring out from the housing. When making adjustments, rotate the thin metal disc very carefully to be sure that the adjusted buttons do not fall out of the housing past the notch in the disc.

After replacing the thin metal disc with the bakelite plate, the disc should not be discarded but should be reserved for future use in resetting buttons or in the event the receiver is reshipped. The receiver should never be transported with the bakelite plate assembled.

Note:—Two of the ten buttons supplied with the dial have long pins. In rare cases a particular station cannot be reached with a short pin button. The two long pin buttons are available for this purpose.

Alignment, Notes, Parts

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be substituted.) Rotate the wave-trap in the receiver section. Set the dial pointer at 60 and feed 600 kc. Adjust the oscillator trimmer (farthest from front) for maximum response. Move the dial pointer to 160 and feed 1600 kc. Adjust the broadcast antenna trimmer (nearest front) for maximum response. Return pointer to 60, feed 600 kc and readjust the broadcast antenna trimmer (central trimmer at left side of chassis). Return pointer to 60, feed 600 kc and readjust the broadcast series pecker, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

REPLACEMENT PARTS

Table with columns: Part No., Description, Price. Includes items like two-band antenna coil, 466 kc wave-trap, 456 kc first i-f transformer, power transformer, resistors, capacitors, trimmers, etc.

GENERAL NOTES
1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism may result.
3. The color coding of the components is as follows:
Grid—green
Grid return—black
B plus—red
Plate—blue
4. The color coding of the power transformer is as follows:
Primary—two black leads
High-voltage secondary—two red and yellow lead
Low-voltage secondary—two green leads
5. The adjustable peaking condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed pecker, C13 on schematic. When using the short-wave coils, make sure the short-wave condenser which has capacity within the color coding of the general wiring is as follows:
6. With a few exceptions, the color coding of the general wiring is as follows:
Plate—blue
B plus—red
Screen—brown
Grid—green
Grid return—black
Cathode—white or yellow
7. The wave-trap in the receiver has been adjusted for maximum response at 456 kc. If, however, persistent interference is experienced from a particular telegraph station, the wave-trap trimmer may be readjusted until interference from the interfering station is at a minimum.
8. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-18, and the Emerson All-Wave Antenna System, Model W-39, are recommended. Instructions for the installation of these antennas are supplied with each station of a large antenna is not desirable we recommend the use of the Emerson All-Wave Antenna, Model W-32. Instructions for the installation of this compact and efficient antenna are supplied with each kit.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 15,000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.
The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signal.
Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers.
The last motion in adjusting trimmers should always be a tightening one, not a loosening one.
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.
Always use as weak a test signal as possible during alignment.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the top of the cans.
The adjustable peaking condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the front of the chassis.
The antenna coils for the broadcast and short-wave bands and the 456 kc wave trap are wound on one form and mounted underneath the chassis deck directly behind the adjustable peaking condenser.
The trimmer nearest the antenna trimmer is the broadcast antenna trimmer. The trimmer nearest the rear of the chassis is the 456 kc wave trap.
The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the rear of the chassis. The trimmers for these coils are accessible through holes in the top of the chassis.
The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-Trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc through a .002 mf paper condenser, to the grid top of the 6A7 tube. The short-wave band clip from the tube). Adjust the four i-f trimmers for maximum response. Feed 15,000 kc to the antenna through a standard dummy antenna (a .0002 mica condenser may be substituted) and adjust the wave-trap trimmer (farthest from front on left side of the chassis) for maximum response. (See General Notes.)

Short-Wave Alignment

Alignment of the short-wave band should precede broadcast alignment)
Use a 400 ohm dummy antenna (a 400 ohm non-inductive resistor in series with the test oscillator antenna lead) when aligning short-wave coils. Rotate the wave-band switch to the short-wave (counter-clockwise) position, and set the dial pointer exactly at 15 megacycles. Feed 15,000 kc to the antenna and adjust the short-wave oscillator trimmer (nearest the front beside variable condenser) for maximum response, and then adjust the antenna trimmer (farthest from front on left side of the chassis) for maximum response. Be very careful to choose the minimum capacity peak on the oscillator trimmer.

When ordering replacement parts specify part numbers.

- *Item number locates the article on the schematic diagram.
†See production changes.
‡These trimmer condensers are part of the coil assemblies and can not be supplied separately.

Alignment, Notes

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 15,000 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a standard dummy antenna for aligning either of the bands. A .0002 mf condenser may be used for the broadcast band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Location of Coils and Trimmer Adjustments

The three i-f transformers are in oblong coil cans located on top of the chassis deck.

The first i-f transformer, part number 4ET-350B, is located to the left of the variable condenser.

The second i-f transformer, part number 4ET-350B, is located behind the variable condenser.

The third i-f transformer, part number 4FT-382, is located to the right of the variable condenser. The trimmers, two for each transformer, are accessible through holes in the top of the cans.

The broadcast series padder is located underneath the chassis (in the corner near the 1C6 tube). The screw adjustment is accessible through a hole in the top of the chassis.

The antenna coil for the two bands is wound on one coil form and mounted underneath the chassis to the right of the variable condenser. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave antenna coil.

The r-f interstage coils for the two bands are wound on one form and mounted underneath the chassis to the left of the first i-f transformer. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave interstage coil.

The oscillator coils for the two bands are wound on one coil form and mounted underneath the chassis to the left of the variable condenser. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil.

i-f Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc through a 0.02 mf paper condenser, to the grid cap of the 1C6 tube (do not remove the grid clip from the tube). Adjust the six i-f trimmers for maximum response.

Short-Wave Alignment (Short-wave alignment should precede broadcast alignment.)

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 15, feed 15,000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the interstage and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

Broadcast Alignment

With the wave-band switch at the broadcast (clockwise) position, set the pointer at 600, feed 600 kc through the antenna (using a standard dummy antenna), and adjust the broadcast series padder for maximum response. Move pointer to 1600, feed 1600 kc to the antenna and adjust the oscillator trimmer for maximum response, then adjust interstage and antenna trimmers. Reset the pointer to 600, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator padder for maximum response. Return to 1600 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

1. The battery complement should be as follows:

Type	No. Required	Eveready Part No.	Battery Manufacturer Burgess Part No.	Ray-o-vac Part No.
3 volt "A".....	1	X-125 or A-600	20F2	P9403
45 volt "B".....	3	385 (plug-in type)	22308 (plug-in type)	P9803 (plug-in type)

2. The receiver is designed for an "A" supply of 2 to 3 volts. A 2 volt storage battery may be used, in which case the 1E1 (ballast) tube, in the chassis becomes unnecessary and may be eliminated as follows:

If it is definitely known that a 2 volt storage battery will always be used it is permissible and advisable to short-circuit the two heavy prongs on the 1E1 tube by connecting them with a short piece of bare wire. Be sure that the two small prongs on the tube are free of this bare wire.

3. The color coding of the i-f transformer leads is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red

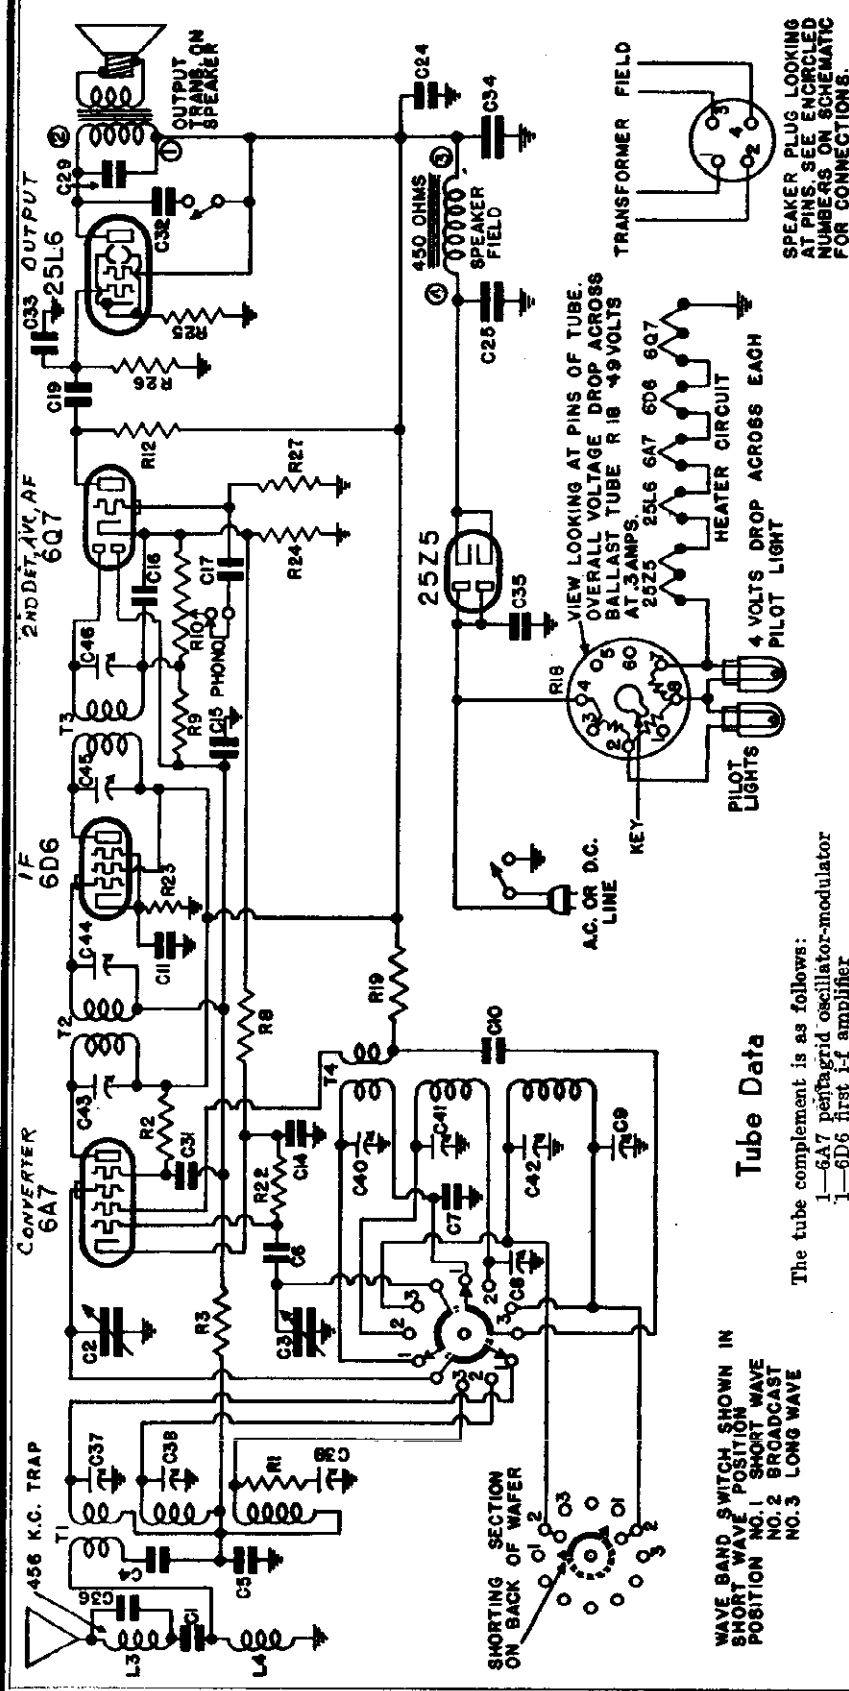

4. Note that all leads in the battery cable are color coded. The two "A" leads are tagged with small metal markers giving the polarity. The battery cable is equipped with three plugs for "B" battery connections. These plugs are all alike and may be inserted in any order in the sockets of the three "B" batteries. The color coding of the battery cable is as follows:

Red	B plus 135
Brown	B plus 67.5
Blue	B neg.
Yellow	A plus 3
Black	A neg.

5. If replacements are made in the r-f section of the circuit, the receiver should be carefully re-aligned.
6. Be very careful not to remove any of the tubes from their sockets with the power switch turned on, as the rapid rise in filament voltage will damage the remainder of the tubes.

Short-Wave Alignment

Set wave-band switch at short-wave (center-lockwise) position. Set pointer at 16, feed 15 megacycles to antenna and adjust short-wave oscillator trimmer and then short-wave antenna trimmer for maximum response.

GENERAL NOTES
1. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a second wire be permitted to come in contact with any metal part of the receiver.

REPLACEMENT PARTS LIST

Table with columns: Part No., Description, Price. Lists various electronic components like capacitors, resistors, coils, and trimmers with their respective part numbers and prices.

When ordering replacement parts specify part numbers.

*When number locates the article on the schematic diagram.
†These condensers are part of coil assemblies and cannot be supplied separately.

3. When operating the receiver on d.c., it may be necessary to reverse the line plug for correct polarity.
4. When applying the external speaker microphone will result.
5. The color coding of the transformers is as follows:
Grid return—black
B plus—green
B plus—red
Plate—blue

6. An electrical phonograph pick-up may be connected to this receiver for playing records. Connections to this receiver may be made at the "phonograph" jack which is located on the rear wall of the receiver chassis. A separate volume control of the potentiometer type is necessary in addition to the phonograph pick-up. The two pick-up lead wires should be connected to the two outside terminals of this volume control. A lead from the center terminal should be plugged into the other hole in the phone jack. The leads to be plugged in the jack should be fitted with tips. The volume control in the receiver should be turned down to the zero volume position when operating the phonograph. The required over-all resistance of the separate volume control will, of course, depend on the type of phonograph pick-up to be used. A matching input transformer must be used if the pick-up is of the low impedance type. In this case the volume control is connected to the secondary of the transformer. It is important that the phonograph leads be removed from the jack when it is desired to operate the receiver for ordinary radio reception.

7. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-84, an antenna system which is built into the receiver chassis, is recommended. Instructions for the installation of this antenna are supplied with each kit. In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.

ADJUSTMENTS

An oscillator with frequencies of 150, 360, 465, 600, 1500 kc should be used. An output meter should be used across the voice coil or output transformer for observing maximum response. Use a standard dummy antenna when aligning either the long-wave or medium-wave bands. A .0025 ohm resistor in series with antenna lead. Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The best motion in adjusting trimmers should always be a tightening one, not a loosening one. Always use as weak a test signal as possible during alignment. Never leave a trimmer with its outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Location of Coils and Trimmers

The two i-f transformers are located on top of the chassis deck. The second i-f transformer is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the top of the cans. The dual adjustable padding condenser is mounted on the left side of the front chassis wall. The antenna coils for the three bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the medium-wave antenna trimmer. The central trimmer is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the long-wave antenna trimmer. The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the medium-wave oscillator trimmer. The central trimmer is the short-wave oscillator trimmer. The trimmer farthest from the front of the chassis is the long-wave oscillator trimmer.

I-F Alignment

Rotate the wave-band switch to the medium-wave (central) position and set the variable condenser to minimum. Feed 466 kc to the grid cap of the 6AV tube. Adjust the four i-f trimmers for maximum response.

Long-Wave Alignment

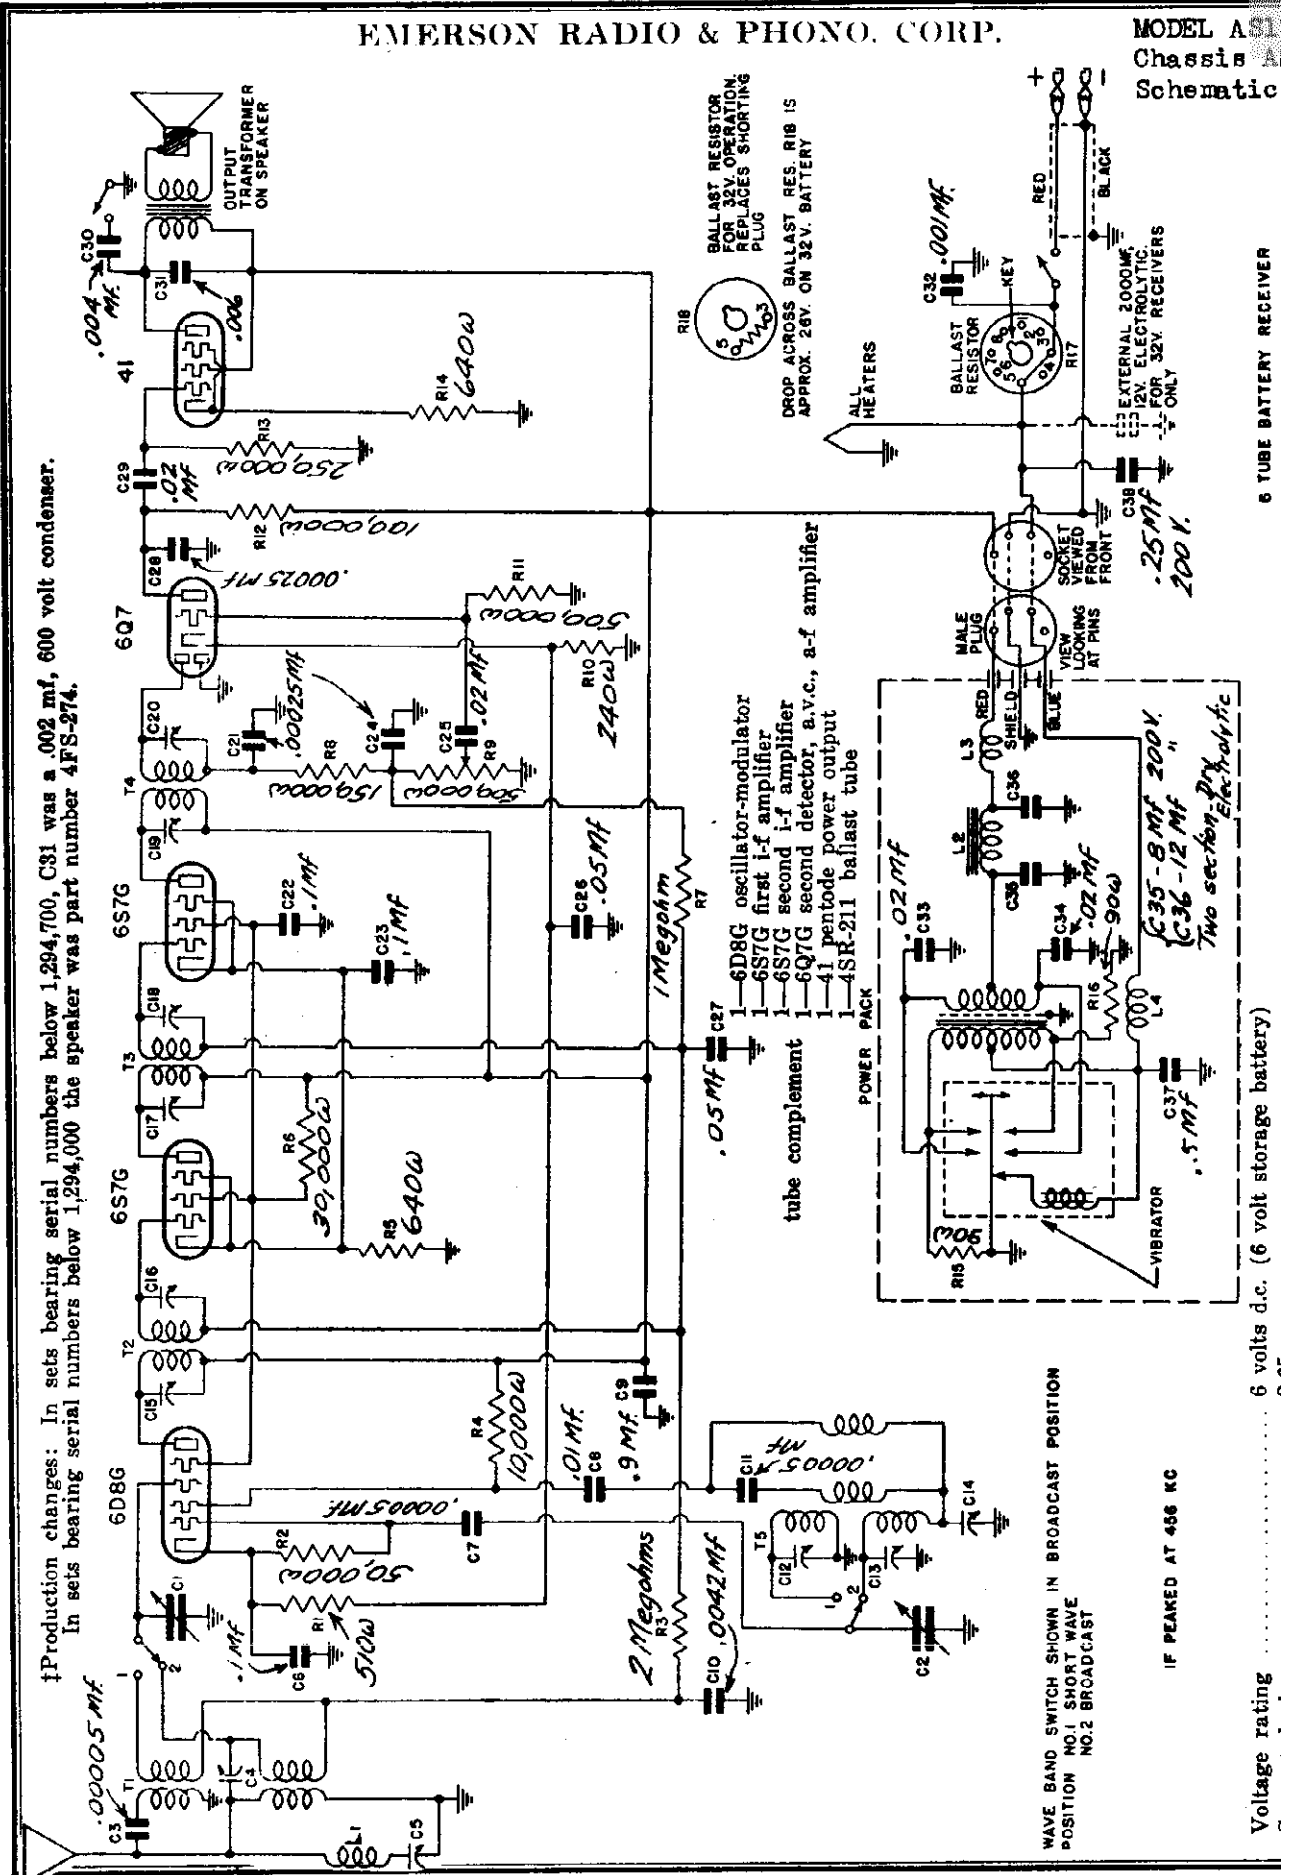

With the wave-band switch at long-wave (clockwise) position set the dial pointer at 150 and feed 150 kc to antenna. Adjust the long-wave series paddler (hex nut on dial paddler) for maximum response. Move pointer to 350 and feed 350 kc to antenna. Adjust the long-wave oscillator trimmer then the long-wave antenna trimmer for maximum response. Reset pointer to 150, feed 150 kc and rock (point back and forth through a small arc) the variable condenser while adjusting long-wave series paddler for maximum response. Reset pointer to 350, feed 350 kc and check alignment. If readjustment is necessary return to 100 kc and repeat entire procedure.

Medium-Wave Alignment

Set switch at medium-wave (central) position and dial pointer at 600. Feed 600 kc to antenna and adjust medium-wave series paddler (slotted screw on dial paddler) for maximum response. Move pointer to 1500, feed 1500 kc and adjust medium-wave oscillator trimmer and then the medium-wave antenna trimmer for maximum response. Reset pointer to 600 feed 600 kc and rock variable condenser while readjusting medium-wave series paddler for maximum response. Reset pointer to 1500, feed 1500 kc and check alignment. If readjustment is necessary return to 600 and repeat entire procedure.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 15,000 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a standard dummy antenna for aligning either of the bands. A .0002 mf condenser may be used for the broadcast band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Location of Coils and Trimmer Adjustments

The first i-f transformer, part number 4ET-350C, is located on top of the chassis to the left of the variable condenser.

The second i-f transformer, part number 4ET-350A is located on top of the chassis behind the variable condenser.

The third i-f transformer, part number 4FT-382B, is located on top of the chassis to the right of the variable condenser.

The trimmer condensers, two for each transformer, are accessible through holes in the top of the cans.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6D8G tube) with the screw adjustment accessible through a hole in the front of the chassis.

The antenna coils for the broadcast and short-wave bands and the 456 kc wave-trap are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the broadcast antenna trimmer. The central trimmer is the short-wave antenna trimmer. The trimmer nearest the rear of the chassis is the 456 kc wave-trap.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc through a 0.02 mf paper condenser to the grid cap of the 6D8G tube (do not remove the grid clip from the tube). Adjust the six i-f trimmers for maximum response. Feed 456 kc to the antenna through a standard dummy antenna and adjust the wave-trap trimmer for *minimum* response. (See General Notes.)

Broadcast Alignment

Rotate the wave-band switch to the broadcast position (clockwise) and set the dial pointer at 600. Feed 600 kc through a standard dummy antenna. Adjust the broadcast series padding condenser for maximum response. Move pointer to 1600, feed 1600 kc and adjust the broadcast oscillator trimmer for maximum response and then adjust the broadcast antenna trimmer for maximum response. Return pointer to 600, feed 600 kc and readjust the series padding condenser, rocking the variable condenser for maximum response.

The set's oscillator is higher in frequency than the signal on the broadcast band, so images should be observed on the low-frequency side of the signals.

Short-Wave Alignment

Rotate the wave-band switch to the short-wave (counter-clockwise) position, and set the dial pointer exactly at 15 megacycles. Feed 15,000 kc to the antenna through a 400 ohm non-inductive resistor and adjust the short-wave oscillator trimmer for maximum response, and then adjust the short-wave antenna trimmer for maximum response. Be very careful to choose the maximum capacity peak on the oscillator trimmer.

The set's oscillator is lower in frequency than the signal (on the short-wave band only), so images should be observed on the high frequency side of the signal.

1. The large, oblong metal box behind the speaker contains the power pack. The function of this power pack is to convert the 6 volt direct current from the storage battery into 150 volt direct current. The vibrator used is of the synchronous type.
2. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
3. Particular care should be taken in connecting the battery to the receiver. The heavy battery cable emerging from the rear of the receiver terminates in two separate leads with clips attached. Note that the clip at the end of the red rubber covered lead is marked with a plus sign (+). This clip should be attached to the *positive* terminal of the six-volt storage battery. The other clip, on the braid covered lead should be attached to the *negative* terminal of the storage battery. It is important to observe the proper polarity in connecting the battery. Reversed connections with the receiver turned on will result in serious damage to the receiver.
4. Make certain that all battery connections make good contact, otherwise the receiver may be noisy. The positive terminal of an unmarked battery may be distinguished by a deposit of green corrosion, which usually collects on this terminal. On most batteries the positive terminal is larger than the negative terminal.
5. The color coding of the leads of the i-f transformers is as follows:

Grid—green	Plate—blue
Grid return—black	B plus—red
6. With few exceptions the color coding of the general wiring is as follows:

Plate—blue	Cathode—white or yellow
B plus—red	Grid—green
Screen—brown	Filament and ground—black
7. The color coding of the leads of the power pack is as follows:

A plus—blue	B plus—red	Common neg.—shield
-------------	------------	--------------------

The receiver may be quickly and easily adapted for operation from a 32 volt power supply. A complete kit, Model W-95, containing the additional parts required for this conversion may be purchased through Emerson dealers. Complete instructions for attaching these additional parts are supplied with each kit.

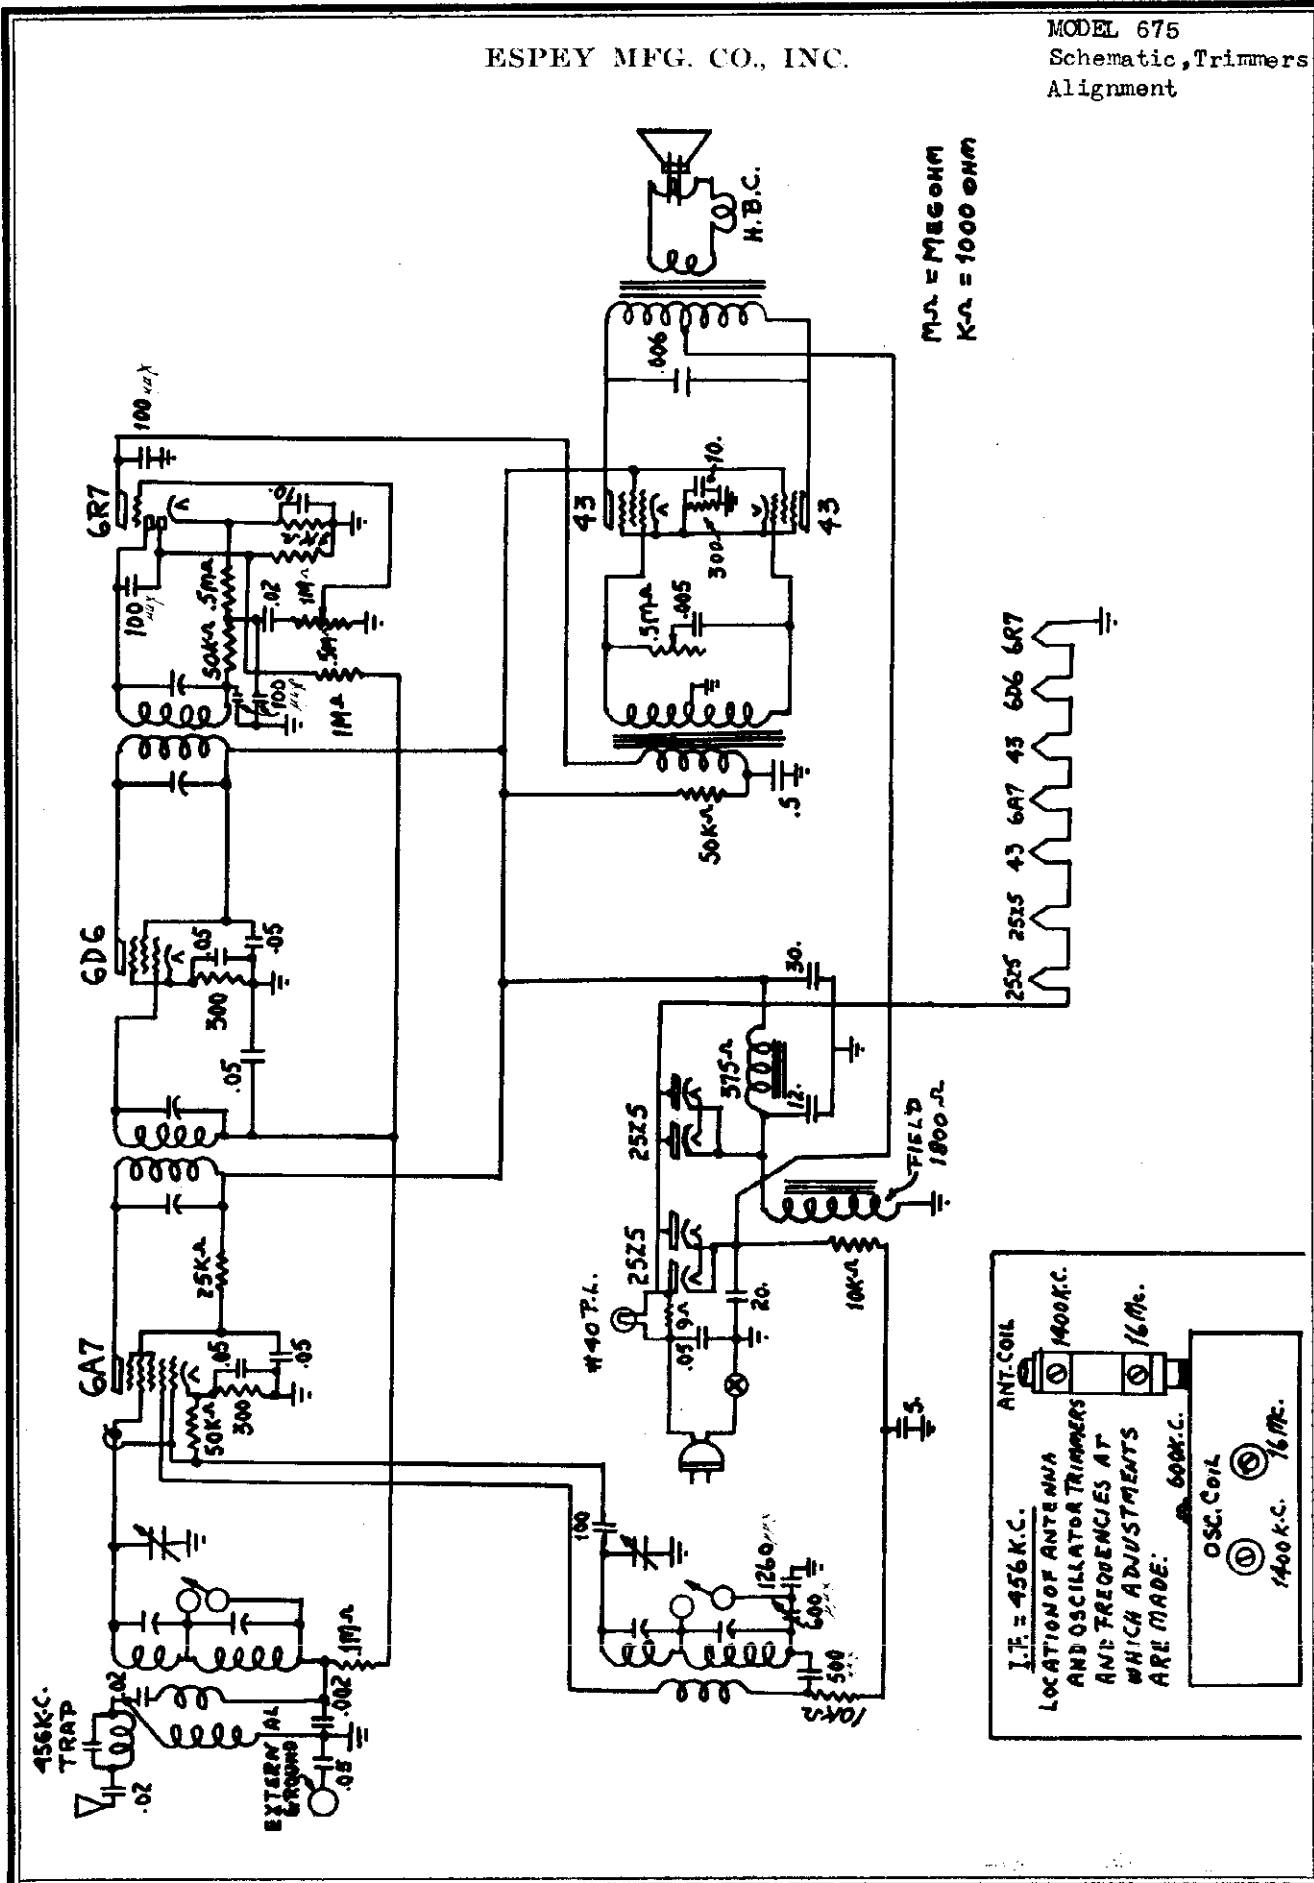

Readings should be taken with a 1,000 ohms-per-volt meter. Voltages listed below are from point indicated to chassis with volume control turned on full and no signal. Battery voltage for these readings was 6.1 volts.

Tube	Plate	Screen	Cathode	Osc. Plate
6D8G osc.-mod.	150	60	4	120
6S7G 1st i-f	150	60	4	—
6S7G 2nd i-f	150	60	4	—

MODEL 267 SF is a two unit speaker for installation behind the radio employing the same receiver header panel in 1936-37 Ford Cars. unit as above, but a separate

SEPARATE SPEAKERS: Model 267 MOTOSET is also available for use with separate speakers instead of the standard 6 1/2 inch speaker supplied with the standard set. These combinations are available as follows:

MODEL 267 SD is a two unit receiver in which the speaker is an 8 inch dynamic in a large housing of its own. This housing mounts on the bulkhead by a single large bolt, and plugs into the receptacle provided for this purpose on the side of the case, near the front.

MODEL 267 SG is a two unit receiver similar to 267 SF, with header speaker for installation in 1936 General Motor Cars.

ALIGNMENT TABLE

Dial Frequency	Generator Frequency	Dummy Antenna	Generator Connected To	Adjust Trimmer
1,000 KC	175 KC	.001 mfd. 50,000 ohms	Control grid of 6A7 tube	T-1, T-2 T-8

Resistance

FAIRBANKS, MORSE & CO.

ALIGNMENT

The models 5C and 6A are AC operated, superheterodyne chassis with automatic volume control. These receivers operate on three bands—broadcast, police-amateur, and short wave, Figure 4. The 6A has the tuning eye, Figures 3 and 4; the 5C does not. Otherwise, the two chassis are identical.

Alignment procedure is given below in chart form, Figures 1 and 2. Make adjustments in the order given. The output meter may be any

low range AC voltmeter, preferably about 0-15 volts. It should be connected from the plate of the 6F6G tube to ground with a .1 mfd. condenser in series with one of the leads. When the hand tends to go off scale, reduce the input from the signal generator and keep the volume control at maximum. If too strong a signal is fed to the receiver and the volume control is used to keep the output meter hand on scale, the A. V. C. will operate and inaccurate alignment will result.

MODEL 5D
Schematic
Batt. Connection

BATTERIES AND CONNECTIONS

the receiver does not operate properly, and then the change must be made one step at a time as described above, otherwise the tubes in the receiver may be damaged. "A" Battery current consumption may be reduced approximately 18 per cent. by removing both dial light bulbs.

"B" BATTERIES. Three 4½-volt "B" Batteries, with standard plug receptacles, are required with the receiver. Good quality, HEAVY DUTY batteries are recommended.

"C" BATTERIES. Two ½-volt "C" Batteries, with standard plug receptacles are required with the receiver.

"A" BATTERY (2VOLT). The Black battery lead is to be connected to "A" minus (-). The Red battery lead is to be connected to "A" plus (+).

"B" AND "C" BATTERIES. Five standard battery plugs will be found on the battery cable. While each has three prongs, it will be noted that three of the plugs have prongs which are all the same size. These are the "B" battery plugs and are to be plugged into the standard receptacles on the three 4½-volt "B" batteries. The remaining plugs, each having one large prong and two small ones are to be plugged into the standard receptacles on the ½-volt "C" batteries.

WARNING—DO NOT ALLOW THE "A" BATTERY LEADS TO COME IN CONTACT WITH ANY OF THE "B" BATTERY TERMINALS. IF THIS HAPPENS THE TUBES, RECEIVER, AND BATTERIES MAY BE

AIR CELL "A" BATTERY. If the receiver is to be operated on an Air Cell Battery only one section of the "resistance link" circuit should be connected. (See "X," Figure 2.) The remaining two leads from the positive (+) "A" lead should be taped or otherwise insulated so they will not come in contact with any of the battery terminals.

TWO-VOLT STORAGE "A" BATTERY. If the receiver is to operate on a Two-Volt Storage "A" Battery, none of the "resistance link" circuit is to be used. The positive (+) "A" connection is to be made as shown under "Y" of Figure 2. The unused leads should be taped so they will not come in contact with the other battery terminals.

THREE-VOLT "A" BATTERY (DRY). If the receiver is to be operated on a Three-Volt "A" Battery, the "resistance link" circuit should be connected as shown under "Z" of Figure 2. The unused leads should be taped so they will not come in contact with any of the battery terminals.

When the Three-Volt "A" Battery becomes so low or weak that the receiver will no longer operate satisfactorily, the connections may then be changed to conform with "X" under Figure 2, thus obtaining a little more operating time from the battery.

When the Three-Volt "A" Battery again becomes so low that the receiver will not operate satisfactorily, the connections may once again be changed to conform with "Y," Figure 2, thus obtaining more operating time from the battery.

MODEL 5D
Alignment, Socket
Trimmers

FAIRBANKS, MORSE & CO.

The model 5D is a battery operated superheterodyne with automatic volume control. It receives signals on three bands—broadcast, police-amateur, and short wave.

Alignment procedure is given below in chart form, figures 1 and 2. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected across the two plates of the 1J6G tube

with a .1 mfd. condenser in series with one of the leads. Set the volume at maximum during the alignment and as the meter hand tends to go off scale, decrease the output from the signal generator. If too strong a signal is fed to the receiver and the volume control is used to keep the output meter hand on scale, the AVC will operate and inaccurate alignment will result.

13	Antenna Lead	18 MC	400 ohm Resistor	Short Wave	18 MC	S.W. Ant.	13		Max.	Check calibration at 6 MC

When aligning the police and short wave bands, care must be taken to see that the trimmers are set on the proper frequency and not on the image. The signal from the oscillator beating with the incoming signal in the mixer tube produces two 456 kilocycle heterodynes, one equal to the oscillator frequency minus the frequency of the incoming signal, and the other equal to the incoming signal minus the oscillator. The former is the one to which the RF and antenna trimmers must be tuned if the receiver is to work correctly over the entire band. The image falls 912 kilocycles below the fundamental signal, so at 18 megacycles the image should be heard at 18 megacycles minus .912 megacycles or 17.1 megacycles approximately.

After setting the oscillator trimmer, increase the input from the signal generator and make sure that the image comes in at the proper point. When you can hear one signal at the frequency to which your generator is set, and one at about 1 megacycle below it, you are ready to finish the alignment. Go back to the fundamental frequency and start peaking the RF trimmer, rocking the tuning condenser slightly as you do so. When you reach a peak, compare the strength of the fundamental signal and the image. If the image is the stronger, you have the wrong peak on the RF trimmer. Find the other peak and again compare the two signals. You will probably find it necessary to increase the generator input greatly in order even to hear the image when you have found the right peak. The antenna trimmer may be peaked in the same manner.

Extreme howling or motorboating on the short wave bands or dead spots near the high frequency end of the dial are good indications that the RF trimmer is improperly aligned and may easily be corrected by resetting it as described above.

MODEL 12A

FAIRBANKS, MORSE & CO.

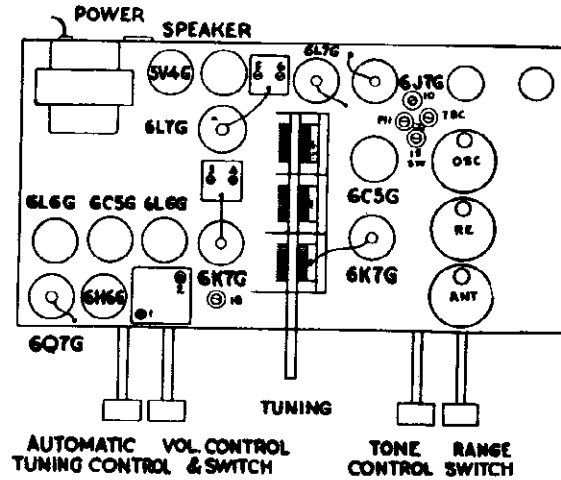

Socket, Trimmers
Voltage, Resistance, Data

The Model 12A is an AC operated superheterodyne with automatic volume control, signa-lite band indication, automatic dial and automatic frequency control. It receives signals on four bands—broadcast, police-amateur, short wave and ultra-short wave.

Alignment procedure is given in the following pages in chart form. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected across the plates of the 6L6G tubes with a .1 mfd. condenser in series with one of the leads. The volume control should be set at maximum during the alignment, and as the meter hand tends to go off scale, the output from the signal generator should be decreased. If too strong a signal is fed to the receiver and the volume control is used to keep the hand on scale, the A.V.C. will operate and inaccurate alignment will result.

When aligning the police and short wave bands, care must be taken to see that the trimmers are set on the proper frequency and not on the image. The signal from the oscillator beating with the incoming signal in the mixer tube produces two 456 kilocycle heterodynes, one equal to the oscillator frequency minus the frequency of the incoming signal and the other equal to the incoming signal minus the oscillator. The former is the one to which the RF and antenna trimmers must be tuned if the receiver is to work correctly over the entire band. The image falls 912 kilocycles below the fundamental signal, so at 18 megacycles the signal should be heard at 18 minus .912 or 17.1 megacycles approximately.

After setting the oscillator trimmer, increase the input from the signal generator and make sure that the image comes in at the proper point. When one signal can be heard at the frequency to which the generator is set and one at about one megacycle below it the alignment is ready to be finished. Go back to the fundamental frequency and start peaking the RF trimmer, rocking the tuning condenser slightly at the same time. When a peak has been reached, compare the strength of the fundamental signal and the image. If the image is the stronger, the RF trimmer is at the wrong peak. Find the other peak and again compare the two signals. It will probably be necessary to increase the generator input greatly in order even to hear the image when the right peak has been found.

MODEL 9A,12A
Automatic Dial Notes
MODEL 12A
Alignment

THE AUTOMATIC DIAL

Since the Model 12AC6 is to be delivered to the customer with the dial set up for the locality in which he lives, it is important that the serviceman be thoroughly familiar with the proper set-up procedure so that he can perform the operation accurately and in a small amount of time.

It would be practically impossible to design a mechanical tuning device for a receiver as selective as the 12A which would automatically tune stations to the exact point of resonance every time without the operator's having to watch some sort of resonance indicator. For that reason automatic frequency control (true AFC tuning) has been incorporated into this model. The automatic frequency control makes up for the slight mechanical tolerances necessary in a device such as the automatic dial by shifting the oscillator to the exact frequency of the station to which the dial is tuned. It will be noted that stations can be "pulled" into resonance with the dial as much as 10 kilocycles away from the point where they would come in with the automatic tuning switch in the "out" position, and for that reason accurate setting of the dial might seem unimportant. It must be remembered, however, that the sensitivity of the receiver is best at the point where the stations come in without A.F.C. and that A.F.C. shifts only the oscillator frequency, not the RF and detector stages. Therefore, accurate setting of the dial is important if good reception is to be obtained on all the stations.

First, throw the automatic tuning switch to the "OUT" position. Then, by means of the outer tuning knob, tune in a station to which a button is to be assigned. Now, place a finger on the button nearest the "click" point (the mid-point at the bottom) and move it over to the "click" point until the dial locks. Care must be taken at this point that in depressing the button without its pyralin covering the metal plunger in the center is not pushed to a point where the dial will not lock. If this difficulty is experienced, try depressing the button with the nail of the forefinger against its outer edge.

After the dial has clicked into place and seems to be locking properly,

release the button taking care not to move the dial. Now, with a pencil or screw driver held in the left hand push the metal plunger at the center of the button in as far as it will go. With the right hand return the station carefully and then release the metal plunger. It may not come all the way out at first and a slight back and forth motion of the vernier knob may be necessary before it snaps out to its original position. Be sure that the plunger is back into place before the station tab is placed in the button.

To check the setting before putting in the station tab, rotate the dial until the button which was just set is somewhere near the top of the dial. Throw the automatic tuning switch to the "IN" position and use the button to tune in the station just as is described under "Automatic Tuning" in the Operating Instructions. Observe the same precautions as were mentioned before in regard to the metal plunger or the setting will have to be made all over again. With the station still tuned in, throw the automatic tuning switch to the "OUT" position and note the amount of detuning which occurs. If the station is detuned more than 3 or 4 kilocycles or to a point where the side bands are just barely audible, there is a closer setting possible and the button should be reset. When the dial seems to be tuning in the station properly, put in the proper station tab and place one of the pyralin discs over it. The tab should be placed so as to read right side up when the button is at the "click" point. This gives a uniform appearance to the dial when the buttons have all been set. In case any of the buttons are not used, put in one of the blank tabs supplied and a pyralin disc.

Set the remainder of the buttons in exactly the same manner, making sure each time that the switch is in the "OUT" position before an adjustment is started.

When the dial setting has been completed, replace the sheets of station tabs in their envelope and put the envelope, together with the one containing the pyralin discs, into the back of the cabinet beside the chassis so that they will be available later should the customer desire to have the dial set for other stations.

21	Antenna	30 MC	400 Ohm Resistor	Ultra S.W.	30 MC		**	Out		**See foot note below.

**No adjustment is required on this band. If signal is not received on or near dial setting, check the oscillator tube, switch contacts, the fixed padding condenser and the coils.
***To check the setting of the discriminator, tune in a fairly weak station near 1000 kilocycles with the automatic tuning switch in the "OUT" position. Peak the station carefully and then throw the switch to the "IN" position. If throwing the switch detunes the station, repeak it carefully using trimmer number 18. A further check may be made by tuning to either side of the station with the switch out until only the side bands are audible and then throwing the switch in. The station should come into resonance as the switch is thrown in. Failure to do so indicates that the adjustment just described has not been careful enough and that it should be made over again.

FIGURE 6
 VOLTAGE AND RESISTANCE TABLE

The voltage and resistance charts in this manual give detailed information regarding the resistance from various points to various other points in the chassis. The measured voltage from the various tube socket contacts to ground is also given. When these charts are followed faithfully, little difficulty should be experienced in finding almost any fault that may develop.

MODEL 12C6
Chassis 120
Alignment

FAIRBANKS, MORSE & CO.

THE OSCILLATOR CIRCUIT

The oscillator circuit is unconventional in that the tickler coils are in the cathode circuit of the 6J7 oscillator tube. This is done to obtain sufficient band coverage with the additional capacity of the 6L7 tube injector grid across the tune circuits and also to accommodate the receiver to operation up to 70 megacycles. One tickler serves for both the Broadcast and Police-Amateur bands and the second tickler serves the short wave band, being switched in and out by the range switch.

The tuned circuit coil for the Ultra Short wave band consists of three pieces of heavy bus wire. The cathode taps into this circuit and causes oscillation at the high frequency end of the band. In addition, on this band, a small coil which is inductively coupled to the bus wire coil is switched into the plate circuit and causes the tube to oscillate at the low frequency end of the band.

On the other bands, the plate of the oscillator tube is by-passed to ground through the padding condensers of the oscillator tuned circuits and assists the oscillator at the low frequency end of each band. The patent on this circuit was issued to MacHabb.

INTERMEDIATE FREQUENCY ALIGNMENT

With the range switch on the broadcast position, the fidelity switch on "Sharp" (clockwise) and the gang condenser closed (maximum capacity), supply a 456 kilocycle signal, stage by stage, to the intermediate frequency amplifier, beginning with the grid of the second intermediate frequency tube. To accomplish this, a .1 MFD. condenser should be connected between the signal generator supply lead and the second intermediate frequency tube.

The trimmers of the third intermediate frequency transformer should be adjusted for maximum output with minimum input from the signal generator. Then the signal generator lead should be moved to the first intermediate frequency tube and the trimmers of the second intermediate transformer should be adjusted. The next step is to supply the signal to the grid of the first detector tube and adjust the trimmers of the first intermediate frequency transformer. This method of procedure is essential because of the extreme selectivity of the receiver. After each stage has been aligned, it is well to go back over all adjustments to make sure they are accurate.

The next step in the intermediate frequency alignment is to supply a very strong (about 1000 microvolt) signal to the grid of the first detector tube through the .1 MFD. condenser. CAUTION: Before the signal is applied to the receiver, the volume control should be retarded to zero. After the signal is applied to the receiver, the volume control should be advanced slowly and carefully until a suitable indication appears on the output meter.

The fidelity switch should be turned to the high fidelity or Third Dimension position. Symmetrical double humps should appear, one on each side of where the sharp resonance point appeared on the "Sharp" position (see Figure 5), when the signal generator is tuned approximately 8 kilocycles on each side of the resonance point. The two humps must be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer must be adjusted until a condition of equal amplitude is obtained. This may be found to be a very difficult adjustment unless an oscillograph is used.

FIGURE 5

USE OF THE OSCILLOGRAPH

A signal generator with a sweep circuit must be employed in making this check. The output of the signal generator should be fed to the grid of the first detector tube in the receiver. The grid clip must be removed from the tube, but, since the first detector is one of the A.V.C. controlled tubes, it is necessary to complete the grid circuit. To accomplish this, connect a large resistor (about 50,000 or 100,000 ohms) between the grid clip and the grid cap of the tube. The low side of the signal generator should be connected to the chassis ground.

The "vertical" binding posts of the oscillograph should be connected to the audio output of the second detector. The high side connection from the "vertical" plates should be made to the point of juncture between resistors 58 and 59. The low side connection may be made to ground. Thus, the audio voltage is applied to the "vertical" plates of the oscillograph.

With the receiver operating on the "Sharp" position, the intermediate frequency amplifier resonance curve will appear on the screen, when the receiver is switched to the "3RD DIMENSION" position, symmetrical double humps, approaching a wide flat top resonance curve, should appear in place of the "Sharp" resonance curve (see Figure 5). Each side of the curve should be of equal amplitude. If this is not the case, the trimmers of the third intermediate frequency transformer should be adjusted until the proper curve is obtained. The adjustment of one trimmer, in addition to effecting its own side of the curve, will reflect in the other side and, for this reason, great care must be exercised in making these adjustments.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each coil are housed in the same can with the coil, with the exception of the oscillator trimmers, these are air dielectric condensers and are mounted on the chassis. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown on Figure 4. It is essential that the bands be aligned in the order they appear in the following instructions. In other words, the police band alignment must be completed before the broadcast band alignment is started because of the interlocking effect of the padding condensers on these bands.

Adjustable series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis, through the holes indicated in Figure 4. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustment, the gang condenser should be retarded back and forth across the signal to insure adjustment to the peak of greatest intensity.

POLICE BAND

With the band selector switch on the police position and the fidelity switch on the "Sharp" position, supply a 5 megacycle signal from the signal generator to the antenna of the receiver, using a 400 ohm carbon resistor in series with the signal generator lead. Tune the receiver to 5 megacycles and then adjust the oscillator, radio frequency and antenna stage police band trimmers for maximum output with minimum input from the signal generator. WARNING: Care must be exercised to avoid aligning the receiver to the image frequency as outlined under "Short Wave Band".

Supply a 1.8 megacycle signal to the receiver and tune the receiver to 1.8 megacycles. Adjust the police band oscillator padding condenser (see Figure 4), for the signal of greatest intensity, rocking the gang condenser back and forth across the signal while making adjustment. Check at 5 megacycles and then at 1.8 megacycles to correct for any frequency change.

BROADCAST BAND

With the band selector switch on the broadcast position, supply a 1500 kilocycle signal from the signal generator to the receiver, using a standard dummy antenna or a 200 Mhfd. condenser in series between the signal generator and the antenna post of the receiver to serve as the dummy antenna. Make certain that the fidelity switch is on the "Sharp" position.

Tune the receiver to 1500 kilocycles and adjust the radio frequency, antenna and oscillator stage broadcast band trimmers for maximum output with minimum input from the signal generator.

Supply a 600 kilocycle signal to the receiver through the same connections. Tune the receiver to 600 kilocycles. Adjust the broadcast band oscillator padding condenser (see Figure 4), for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Recheck at 1500 kilocycles and then at 600 kilocycles and make any frequency corrections that appear necessary.

LONG WAVE BAND

With the band selector switch on the long wave position, supply a 350 kilocycle signal from the signal generator to the antenna of the receiver, using a standard dummy antenna or a 200 Mhfd. condenser in series with the lead. Make sure the fidelity switch is on the "Sharp" position. Tune the receiver to 350 kilocycles and adjust the oscillator, radio frequency and antenna stage trimmer condensers for maximum output with minimum input from the signal generator.

NOTE - The Long Wave oscillator trimmer is accessible through a hole in the chassis bottom shield plate.

Supply a 175 kilocycle signal to the receiver through the same connections used in the previous adjustment. Tune the receiver to 175 kilocycles. Adjust the long wave oscillator padding condenser for the peak of greatest intensity while rocking the tuning condenser back and forth across the signal. Recheck at 350 kilocycles and then at 175 kilocycles as many times as may be necessary to obtain satisfactory tracking.

SHORT WAVE BAND

Turn the band selector switch to the short wave position. Supply an 18 megacycle signal from the signal generator through a 400 ohm carbon resistor (dummy antenna) to the antenna post of the receiver. Tune the receiver to 18 megacycles on the dial. Adjust the short wave band oscillator trimmer condenser for maximum output with minimum input from the signal generator, then adjust the short wave band antenna and Radio Frequency stage trimmer condensers for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity. The 6 megacycle signal should be received near 6 megacycles on the dial. If the signal is not received check the oscillator tube, switch connections, the fixed padding condenser and the coils. No adjustment is required at this point. Check the calibration and, if necessary, readjust all three stages.

WARNING: The image signal should be received at approximately 17 megacycles after the above adjustments have been made. If it cannot be located, the oscillator has probably been aligned to the image frequency and the oscillator trimmer must be backed out until the proper signal comes in at 18 megacycles and the somewhat weaker image is received at approximately 17 megacycles. If this readjustment is necessary, it will also be necessary to again align all three trimmers for maximum output.

ULTRA SHORT WAVE BAND

No adjustment is required on this band. If signals are not properly received check the oscillator tube, switch contacts, fixed condenser and the coils.

MODELS 42CIB, 42TOB
Chassis 42
Schematic, Notes

The model 42 chassis employs a type 1C6 pentagrid converter. The incoming signal is supplied to this tube through a preselector coil arrangement. This tube serves the dual function of first detector and oscillator. A type 1B4 is employed as the intermediate frequency amplifier. This tube and the two intermediate frequency transformers are responsible for most of the selectivity and gain in the receiver. A type 1B4 tube performs the dual function of detector and first audio amplifier. The output of the second type 1B4 tube is resistance coupled to a type 33 tube in the power output stage. A storage battery having a capacity of at least 135 ampere hours should be used with the receiver.

Socket, Trimmers, Notes

Alignment, Batt. Conn.

FAIRBANKS, MORSE & CO.

BATTERIES

This receiver has been designed to operate equally well on an Air Cell "A" Battery or a Two Volt Storage Battery as the "A" supply.

A three volt dry battery may be used with the receiver but the life of such a battery is usually not as long as that of the other types.

AIR CELL "A" BATTERY

If the receiver is to be operated on an air cell battery only one section of the "resistance link" circuit should be connected (See "1" Figure 3). The remaining two leads from the positive (+) "A" lead should be taped or otherwise insulated so they will not come in contact with any of the other battery terminals.

TWO VOLT STORAGE "A" BATTERY

If the receiver is to be operated on a Two Volt Storage "A" Battery, none of the "resistance link" circuit is to be used. The Positive (+) "A" connections are to be made as shown under "2" of Figure 3. The unused leads should be taped so they will not come in contact with the other battery terminals.

THREE VOLT "A" BATTERY

If the receiver is to be operated on a Three Volt "A" Battery the "resistance link" circuit should be connected as shown under "3" of Figure 3. The unused leads should be taped so they will not come in contact with any of the battery terminals.

When the Three Volt "A" Battery becomes so low or weak that the receiver will no longer operate satisfactorily, the connections may then be changed to conform with "1" under Figure 3, thus obtaining a little more operating time from the battery.

When the Three Volt "A" Battery again becomes so low that the receiver will not operate satisfactorily, the connections may once more be changed, to conform with "2" of Figure 3, thus again obtaining more operating time from the battery.

NOTE - These changes must not be made until the battery becomes so low that the receiver does not operate properly, and then the change must be made one step at a time as described above otherwise the tubes in the receiver may be damaged.

"B" BATTERIES

Three 45 volt "B" batteries, with standard plug receptacles, are required with the receiver. Good quality, HEAVY DUTY batteries are recommended.

"C" BATTERIES

16 1/2 volts of "C" battery are required on the receiver. This voltage may be obtained from a standard 22 1/2 volt battery, with a standard plug receptacle, with a 16 1/2 volt tap.

BATTERY CABLE CONNECTIONS

"A" BATTERY

The Black battery lead is to be connected to "A" minus (-). The Red battery lead is to be connected to "A" plus (+). See Figure 3.

"B" AND "C" BATTERIES

Four Standard Battery Plugs will be found on the battery cable, three of these are identical to each other and are to be plugged into the Standard Receptacles on the three "B" batteries. The remaining plug, with the different terminal arrangement, should be plugged into the "C" battery.

WARNING - DO NOT ALLOW THE "A" BATTERY LEADS TO COME IN CONTACT WITH ANY OF THE "B" BATTERY TERMINALS. IF THIS HAPPENS, THE TUBES, RECEIVER AND BATTERIES MAY BE SERIOUSLY DAMAGED.

SUGGESTED SERVICE PROCEDURE

If the receiver does not operate properly, first test all batteries and then test all tubes in a reliable tube tester or, better still, replace the tubes in the receiver, one by one, with tubes known to be good. Most difficulties will be found in or centered around defective tubes, or batteries. If, after replacing any defective tubes or batteries, the receiver is still inoperative, remove the chassis from the cabinet and conduct a careful resistance analysis using the resistance values shown on the schematic diagram as a guide. This will usually reveal the source of the difficulty.

ALIGNMENT PROCEDURE

To insure obtaining the performance the model 42 chassis is capable of delivering, it is essential that it be aligned perfectly. For this reason, it is urged that the following instructions be studied carefully before any alignment adjustments are attempted.

Proper adjustment of the various tuned circuits will be possible only through the use of an accurate and reliable signal generator employed in conjunction with an output meter, which may be connected from plate to ground on the output tube. A fixed condenser (.1 Mfd.) should be connected in series with the output meter.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

INTERMEDIATE FREQUENCY

- 1.- Turn the gang condenser to maximum capacity (fully meshed).
- 2.- Set the dial pointer at 530 kilocycles and then tighten the set screw.
- 3.- Supply a 456 kilocycle signal from the signal generator to the grid of the type 105 first detector tube through a .1 Mfd. condenser connected in series with the signal generator lead.
- 4.- Adjust the radio frequency trimmer ("B" Figure 1) for maximum output with minimum input from the signal generator.

- 4.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each stage located on the gang condenser (see Figure 1)

- 1.- Tune the receiver to 1500 kilocycles.
- 2.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.
- 3.- Adjust the oscillator stage trimmer condenser ("A" Figure 1) for maximum output with minimum input from the signal generator.

RESISTORS

The **BODY COLOR** represents the **FIRST FIGURE** of the resistance value
The **END COLOR** represents the **SECOND FIGURE** of the resistance value
The **DOT COLOR** represents the **NUMBER OF CIPHERS** following the first two figures

4.- The 6 megacycle signal should be received near 6 megacycles on the dial. If this is not the case, check the oscillator tube, switch connections, the fixed padding condenser (C-4) and coils. No adjustment is necessary on this band.

5.- Repeat 1, 2, 3 and 4 at 3.6 megacycles.

THE ANTENNA

A good outside antenna is recommended for best results. An inside antenna will usually give satisfactory results on local broadcast stations, but it cannot be relied upon for distant and short wave reception.

The most satisfactory antenna for any installation will vary, depending largely upon local structural details and sources of interference. It should be kept as far as possible from buildings, trees and other obstructions. The antenna should not run parallel to nearby power lines and should not run near a tin roof or any metallic structure. The length of the antenna has much to do with the volume of the receiver. As the length of the antenna is increased, the volume on distant stations will be increased.

The most suitable antenna for use in large cities or congested radio districts, where interference is a serious problem, is the doublet. In small centers of population, where interference is not serious, a single wire antenna having a total length of from 75 to 100 feet, erected as high as possible, with a good insulator at each end, will prove satisfactory. The lead-in should go to the receiver by the most direct route and should be kept away, as far as possible, from obstructions. Such an antenna will have less directional properties and less tendency to pick up power line interference than a low antenna with a long horizontal lead.

POWER TRANSFORMER

Lead Color	Voltage
Black	115 Volt Primary
Green	6.3 Volt Filament
Yellow	5.0 Volt Filament
Red	High Voltage Sec.
Red & White	High Voltage C.T.

INTERMEDIATE FREQUENCY ALIGNMENT

- 1.- Turn the gang condenser to maximum capacity (fully meshed.)
- 2.- Set the band selector switch on the "Broadcast" position.
- 3.- Supply a 455 kilocycle signal from the signal generator to the antenna lead of the receiver through a .1 Mfd. condenser connected in series with the signal generator lead.
- 4.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for the broadcast band are on the gang condenser. These trimmers are used for aligning the high frequency end of the broadcast band. The location of the trimmers is shown in Figure 1.

The oscillator adjustable series padding condenser is used for tracking the oscillator at the low frequency end of the broadcast band. The padding condenser may be adjusted from the side of the chassis through the hole indicated in Figure 1. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT

Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity), place the dial pointer at 540 kilocycles (gang condenser still closed) and then proceed with the following adjustments.

BROADCAST BAND

- 1.- Turn the band selector switch to the broadcast (Counter-Clockwise) position.
- 2.- Tune the receiver to 1500 kilocycles.
- 3.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mfd. (.002 Mfd.) condenser, connected in series with the signal generator lead.
- 4.- Adjust the trimmer condensers on the gang condenser (Figure 1) for maximum output with minimum input from the signal generator.
- 5.- Tune the receiver to 600 kilocycles.
- 6.- Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
- 7.- Adjust the broadcast band oscillator padding condenser "B" (side of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

- 1.- Turn the band selector switch to the short wave position (clockwise).
- 2.- Tune the receiver to 6 megacycles.
- 3.- Supply a 6 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

MODELS 58T1, 58T2

Chassis 58

Alignment, Trimmers

Socket, Notes

FAIRBANKS, MORSE & CO.

INTERMEDIATE FREQUENCY ALIGNMENT

- 1.- Turn the gang condenser to maximum capacity (full meshed). With the Range Switch on the broadcast position.
- 2.- Supply a 456 kilocycle signal from the signal generator to the grid of the first detector tube (5A8G) through a .1 Mfd. condenser connected in series with the signal generator lead.
- 3.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 1.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condenser may be adjusted from the top of the chassis through the hole indicated in Figure 1. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT

Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity). Loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and then tighten the screw.

NOTE - The three bands must be aligned in the following order: First, police; second, broadcast; third, short wave.

POLICE BAND

- 1.- Turn the band selector switch to the police band (center) position.
- 2.- Tune the receiver to 6 megacycles.
- 3.- Supply a 6 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the police band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator, then adjust the police band antenna stage trimmer for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 5.- Tune the receiver to 2.4 megacycles.
- 6.- Supply a 2.4 megacycle signal to the receiver through the same connections used on the previous adjustment.
- 7.- Adjust the police band oscillator padding condenser (top of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 6 megacycles and then at 2.4 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

BROADCAST BAND

- 1.- Turn the band selector switch to the broadcast (counter-clockwise) position.
- 2.- Tune the receiver to 1500 kilocycles.
- 3.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna of a 200 Mfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.
- 4.- Adjust the broadcast band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the broadcast band antenna stage trimmer for maximum output.
- 5.- Tune the receiver to 600 kilocycles.
- 6.- Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
- 7.- Adjust the broadcast band oscillator padding condenser (top of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.
- 9.- Supply a 456 kilocycle signal to the antenna of the receiver through the dummy antenna with the gang condenser at 600 kilocycles.

SHORT WAVE BAND

- 1.- Turn the band selector switch to the short wave (clockwise) position.
- 2.- Tune the receiver to 20 megacycles.
- 3.- Supply a 20 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.

- 4.- Adjust the short wave band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the short wave band antenna stage trimmer for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 5.- The 4 megacycle signal should be received near 8 megacycles on the dial. If this is not the case, check the oscillator tube, switch connections, the fixed padding condenser and the coils. No adjustment is necessary at this point.

WARNING - The image signal should be received at approximately 19 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 20 megacycles and the image at approximately 19 megacycles. If readjustment is found necessary, the antenna stage trimmer should also be checked again.

ANTENNA AND GROUND CONNECTIONS

The BLUE wire on the receiver is to be connected to the antenna. The BLACK wire on the receiver is to be connected to the ground. When a FAIRBANKS-MORSE ANTENNA is used, the BLUE wire from the receiver is to be connected to the red wire on the antenna set coupler and the BLACK wire from the receiver is to be connected to the black wire on the antenna set coupler and to a good ground.

The most suitable antenna for use in large cities or congested radio districts, where interference is a serious problem, is the doublet. In small centers of population, where interference is not serious, a single wire antenna having a total length of from 75 to 100 feet, erected as high as possible, with a good insulator at each end, will prove satisfactory. The lead-in should go to the receiver by the most direct route and should be kept away, as far as possible, from obstructions. Such an antenna will have less directional properties and less tendency to pick up power line interference than a low antenna with a long horizontal lead.

FAIRBANKS, MORSE & CO.

DIAL ADJUSTMENT

Before making any radio frequency alignment adjustments, close the variable tuning condenser (Maximum capacity), place the dial pointer at 540 kilocycles (gang condenser still closed) and then proceed with the following adjustments.

BROADCAST BAND

1. Turn the band selector switch to the broadcast (Counter-Clockwise) position.
2. Tune the receiver to 1500 kilocycles.
3. Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.
4. Adjust the trimmer condensers on the gang condenser (Figure 1) for maximum output with minimum input from the signal generator.
5. Tune the receiver to 600 kilocycles.
6. Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
7. Adjust the broadcast band oscillator padding condenser (top of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
8. Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.
9. Supply a 456 kilocycle signal to the antenna of the receiver through the dummy antenna with the gang condenser at 600 kilocycles.
10. Adjust the wave trap trimmer (see Figure 1) for minimum output.

SHORT WAVE BAND

1. Turn the band selector switch to the short wave position (clockwise).
2. Tune the receiver to 6 megacycles.
3. Supply a 6 Megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
4. The 6 megacycle signal should be received near 6 megacycles on the dial. If this is not the case, check the oscillator tube, switch connections, the fixed padding condenser (C-6) and coils. No adjustment is necessary on this band.
5. Repeat 1, 2, 3, and 4 at 3.6 megacycles.

FIGURE 1
TOP VIEW OF THE MODEL 68 CHASSIS

INTERMEDIATE FREQUENCY ALIGNMENT

1. Turn the gang condenser to maximum capacity (fully meshed.)
2. Set the band selector switch on the "Broadcast" position.
3. Supply a 456 kilocycle signal from the signal generator to the antenna lead of the receiver through a .1 Mfd. condenser connected in series with the signal generator lead.
4. Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for the broadcast band are on the gang condenser. These trimmers are used for aligning the high frequency end of the broadcast band. The location of the trimmers is shown in Figure 1.

The oscillator adjustable series padding condenser is used for tracking the oscillator at the low frequency end of the broadcast band. The padding condenser may be adjusted from the top of the chassis through the hole indicated in Figure 1. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

INTERMEDIATE FREQUENCY ALIGNMENT:—Supply a 456 KC signal from the sig. gen. to the antenna lead thru a .1 mfd. cond. in series with the signal gen. Adjust the three trimmers for maximum output with minimum input from the osc.

RADIO FREQUENCY ALIGNMENT: With min. cap. of var. cond. set dial at 540 KC. Tune the receiver at 1500 KC. — Supply a 1500 signal from sig. gen. to antenna thru 200 mmfd. cond., connected in series with sig. gen. lead. Adj. trimmers for max. OP. Tune receiver to 600 KC — Supply 600 KC to ant. thru the same connection as above. Low freq. of band does not employ an osc. padding cond. but is tracked by means of a split section of gang cond. The wave trap requires no adjustment.

MODELS 72C2, 72C3, 72T3
Chassis 72

FAIRBANKS, MORSE & CO.

Alignment, Socket
Trimmers, Data

INTERMEDIATE FREQUENCY ALIGNMENT

- 1.- Turn the gang condenser to maximum capacity (fully meshed). With the range switch on the broadcast position.
- 2.- Supply a 455 kilocycle signal from the signal generator to the grid of the first detector tube (6A86) through a .1 Mfd. condenser connected in series with the signal generator lead.
- 3.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 1) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil except the oscillator trimmers. These are air dielectric condensers and are mounted on the chassis. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 1.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis through the holes indicated in Figure 1. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT

Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity), loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and then tighten the screw.

POLICE BAND

- 1.- Turn the band selector switch to the police band (center) position.
- 2.- Tune the receiver to 6 megacycles.
- 3.- Supply a 5 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the police band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator, then adjust the police band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 2.5 megacycles.
- 6.- Supply a 2.5 megacycle signal to the receiver through the same connections used on the previous adjustment.
- 7.- Adjust the police band oscillator padding condenser (top of chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 6 megacycles and then at 2.5 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

BROADCAST BAND

- 1.- Turn the band selector switch to the broadcast (counter-clockwise) position.
- 2.- Tune the receiver to 1500 kilocycles.
- 3.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.
- 4.- Adjust the broadcast band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the broadcast band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 600 kilocycles.
- 6.- Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
- 7.- Adjust the broadcast band oscillator padding condenser (top of the chassis, see Figure 1) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

- 1.- Turn the band selector switch to the short wave (clockwise) position.
- 2.- Tune the receiver to 20 megacycles.
- 3.- Supply a 20 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the short wave band oscillator trimmer condenser (Figure 1) for maximum output with minimum input from the signal generator. Then adjust the short wave band antenna and radio frequency stage trimmers for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 5.- The 8 megacycle signal should be received near 8 megacycles on the dial. If this is not the case check the oscillator tube, switch connections, the fixed padding condenser and the coils. No adjustment is required at this point.

WARNING

The image signal should be received at approximately 19 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 20 megacycles and the image approximately 19 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

FIGURE 3
TOP VIEW OF THE MODEL 73 CHASSIS

INTERMEDIATE FREQUENCY ALIGNMENT

- 1.- Turn the gang condenser to maximum capacity (fully meshed). Set the band selector switch on the broadcast position.
- 2.- Supply a 456 kilocycle signal from the signal generator to the grid of the first detector tube (6A7) through a .1 Mfd. condenser connected in series with the signal generator lead.
- 3.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 3) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil except the oscillator trimmers. These are air dielectric condensers and are mounted on the chassis. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 3.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis through the holes indicated in Figure 3. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

DIAL ADJUSTMENT

Before making any radio frequency alignment adjustments, close the variable tuning condenser (maximum capacity), loosen the screw that secures the dial pointer, place the pointer in a horizontal position (gang condenser still closed) and then tighten the screw.

POLICE BAND

- 1.- Turn the band selector switch to the police band (center) position.
- 2.- Tune the receiver to 6 megacycles.
- 3.- Supply a 6 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the police band oscillator trimmer condenser (Figure 3) for maximum output with minimum input from the signal generator, then adjust the police band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 2.5 megacycles.
- 6.- Supply a 2.5 megacycle signal to the receiver through the same connections used on the previous adjustment.
- 7.- Adjust the police band oscillator padding condenser (top of chassis, see Figure 3) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 6 megacycles and then at 2.5 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

BROADCAST BAND

- 1.- Turn the band selector switch to the broadcast (counter-clockwise) position.
- 2.- Tune the receiver to 1500 kilocycles.
- 3.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mfd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.

- 4.- Adjust the broadcast band oscillator trimmer condenser (Figure 3) for maximum output with minimum input from the signal generator. Then adjust the broadcast band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 600 kilocycles.
- 6.- Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
- 7.- Adjust the broadcast band oscillator padding condenser (top of chassis, see Figure 3) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

- 1.- Turn the band selector switch to the short wave (clockwise) position.
- 2.- Tune the receiver to 20 megacycles.
- 3.- Supply a 20 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the short wave band oscillator trimmer condenser (Figure 3) for maximum output with minimum input from the signal generator. Then adjust the short wave band antenna and radio frequency stage trimmers for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 5.- The 8 megacycle signal should be received near 8 megacycles on the dial. If this is not the case check the oscillator tube, switch connections, and fixed padding condenser and the coils. No adjustment is required at this point.

WARNING

The image signal should be received at approximately 19 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 20 megacycles and the image at approximately 19 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

SUGGESTED SERVICE PROCEDURE

If the receiver does not operate properly, test all tubes in a reliable tube tester or, better still, replace the tubes in the receiver, one by one, with tubes known to be good. Care must be exercised to see that the switch is turned off before any tubes are removed from the receiver, since some of them are two volt tubes, while others are six volt tubes, their filaments being connected in a series parallel arrangement. If, after replacing any defective tubes, the receiver is still inoperative, remove the chassis from the cabinet and conduct a careful resistance and voltage analysis.

The voltage and resistance charts in this manual give detailed information regarding the resistance from various points to various other points in the chassis. The measured voltage from the various tube socket contacts to ground is also given. When these charts are followed faithfully, little difficulty should be experienced in finding almost any fault that may develop.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

FUSE

In case of difficulty, the fuse located in a metal cartridge near the end of the positive (red) battery lead should be checked. A 15 ampere fuse, FAIRBANKS-MORSE part number 5605, should be used for replacement purposes.

BATTERY

A storage battery having a capacity of at least 135 ampere hours should be used with the receiver. The storage battery should be located as far from the chassis of the receiver as the battery cables will permit. Attach the long, red lead from the receiver to the positive (+) side of the storage battery. Attach the long, black lead from the receiver to the negative (-) side of the battery.

MODELS 91C4, 91C5, 91T4

Chassis 91

Socket, Trimmers

Alignment, Data

FAIRBANKS, MORSE & CO.

NOTE - All adjustments should be made with the volume control "full on". Any desired variation in signal strength should be obtained by adjusting the output of the signal generator.

FIGURE 4
TOP VIEW OF THE MODEL 91 CHASSIS

INTERMEDIATE FREQUENCY ALIGNMENT

- 1.- Turn the gang condenser to maximum capacity (fully meshed). Band switch on broadcast position.
- 2.- Supply a 456 kilocycle signal from the signal generator to the grid of the first detector tube through a .1 Mfd. condenser connected in series with the signal generator lead.
- 3.- Adjust the four trimmers of the two intermediate frequency transformers (see Figure 4) for maximum output with minimum input from the service oscillator.

RADIO FREQUENCY ALIGNMENT

The parallel or high frequency trimmer condensers for each coil are housed in the same shield can with the coil. With the exception of the oscillator trimmers, these are air dielectric condensers and are mounted on the chassis. These trimmers are used for aligning the high frequency end of each band. The location of the various trimmers is shown in Figure 4.

The oscillator, adjustable, series padding condensers are used for tracking the oscillator at the low frequency end of each band. The padding condensers may be adjusted from the top of the chassis through the holes indicated in Figure 4. Since a fixed mica padding condenser is employed on the short wave band, no adjustment is necessary. While making padding condenser adjustments, the gang condenser should be rotated back and forth across the signal to insure adjustment to the peak of greatest intensity.

BROADCAST BAND

- 1.- Turn the band selector switch to the broadcast (clockwise) position.
- 2.- Tune the receiver to 1500 kilocycles.
- 3.- Supply a 1500 kilocycle signal from the signal generator to the antenna lead of the receiver through a standard dummy antenna or a 200 Mafd. (.0002 Mfd.) condenser, connected in series with the signal generator lead.
- 4.- Adjust the broadcast band oscillator trimmer condenser (Figure 4) for maximum output with minimum input from the signal generator. Then adjust the broadcast band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 600 kilocycles.
- 6.- Supply a 600 kilocycle signal to the antenna of the receiver through the same connections as previously used.
- 7.- Adjust the broadcast band oscillator padding condenser (top of chassis, see Figure 4) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 1500 kilocycles and then at 600 kilocycles. Make any adjustments that are necessary to obtain satisfactory calibration.

POLICE BAND

- 1.- Turn the band selector switch to the police band (center) position.
- 2.- Tune the receiver to 5.4 megacycles.
- 3.- Supply a 5.4 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the police band oscillator trimmer condenser (Figure 4) for maximum output with minimum input from the signal generator, then adjust the police band radio frequency and antenna stage trimmers for maximum output.
- 5.- Tune the receiver to 1.8 megacycles.
- 6.- Supply a 1.8 megacycle signal to the receiver through the same connections used on the previous adjustment.

- 7.- Adjust the police band oscillator padding condenser (top of chassis, see Figure 4) for maximum output with minimum input from the signal generator, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 8.- Check at 5.4 megacycles and then at 1.8 megacycles and make any adjustments that are necessary to obtain satisfactory calibration.

SHORT WAVE BAND

- 1.- Turn the band selector switch to the shortwave (clockwise) position.
- 2.- Tune the receiver to 18 megacycles.
- 3.- Supply an 18 megacycle signal from the signal generator to the antenna lead of the receiver through a 400 ohm carbon resistor (dummy antenna), connected in series with the signal generator lead.
- 4.- Adjust the short wave band oscillator trimmer condenser (in Figure 4) for maximum output with minimum input from the signal generator. Then adjust the short wave band antenna and radio frequency stage trimmers for maximum output, at the same time rocking the tuning condenser back and forth across the signal to insure the peak of greatest intensity.
- 5.- The 6 megacycle signal should be received near 6 megacycles on the dial. If the signal is not received check the oscillator tube, switch connections, the fixed padding condenser and the coils. No adjustment is required at this point.
- 6.- Check and, if necessary, readjust all three stages for maximum output with minimum input from the signal generator.

WARNING

The image signal should be received at approximately 17 megacycles on the dial. If not, the oscillator has been aligned to the image frequency and the oscillator trimmer condenser must be backed out until the correct signal is received at 18 megacycles and the image at approximately 17 megacycles. If readjustment is found necessary, the antenna and radio frequency stage trimmers should also be checked again.

ULTRA SHORT WAVE BAND

No adjustment is required on this band. If signals are not properly received check the oscillator tube, switch contacts, the fixed padding condenser, and the coils.

MODEL 7405-1
4 Tube - AC-DC - Receiver
(Airchief)

4-Tube AC-DC Receiver
For Use on 110-115 VOLTS AC OR DC Current Only

This receiver is a four-tube tuned-radio-frequency type which operates on either AC or DC current. It will provide very satisfactory entertainment for those who desire a small set.

First, carefully remove all packing material from the set and around the tubes. See that all tubes are pushed down tightly in the sockets, all grid caps on top of tubes properly connected, and tube shields in place. Test by means of a lamp that there is power at the receptacle you have chosen for your radio, and be sure that the voltage is 110 volts. Disconnect attachment cord to outlet.

SUPPLY VOLTAGE

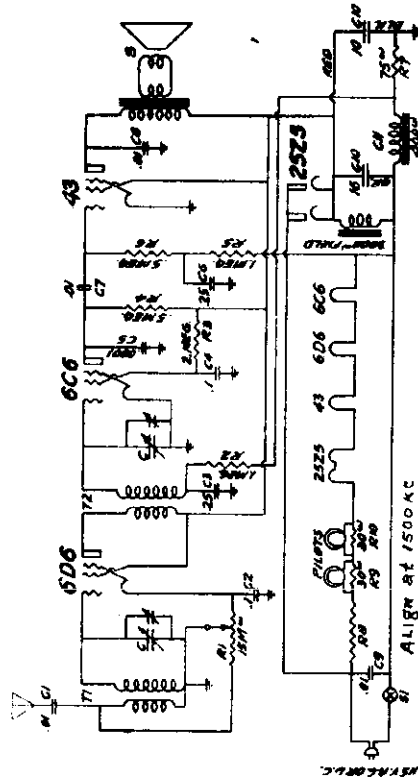

This receiver operates from any 110 volt light socket of any frequency AC or straight DC. When operating on a DC socket, the plug may have to be reversed in the socket to obtain the correct polarity, as it will work only in one position on DC current, but in either position on AC current.

ANTENNA

A 20-foot coil of antenna wire is supplied connected to the receiver. This is usually sufficient for most locations if it is unrolled and laid on the floor or thrown out of window. However, in some buildings of steel construction it may be necessary to use an outside antenna to obtain satisfactory results. Connect it to end of the antenna supplied.

GROUND

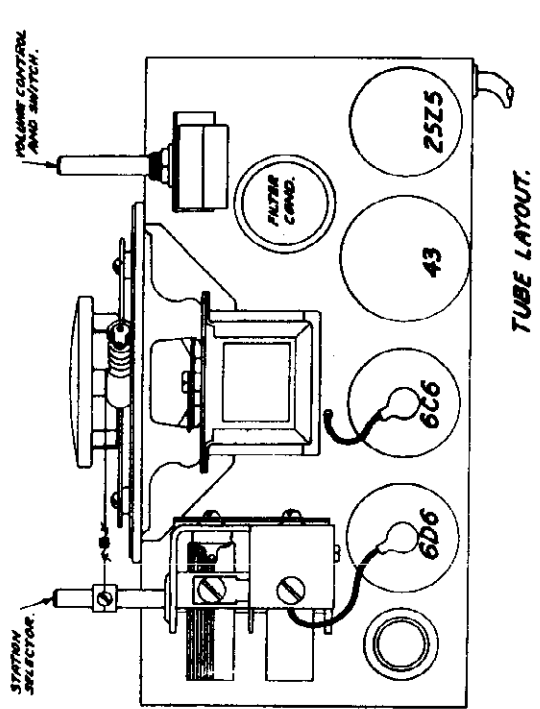

No ground connection is necessary. There is no provision made for its use on this set.

Model 7422-3
"AIR CHIEF"

GENERAL INFORMATION This is a 5-tube tuned radio frequency receiver and operates from either an alternating or a direct current lighting circuit having the usual 110-115 volt terminal potential.

After taking the set out of its carton, be sure that all packing material has been removed. The line cord is un-wound and later inserted in the nearest receptacle. First, however, be sure that the line voltage is of the value mentioned above.

ANTENNA A 20-foot coil of antenna wire is supplied attached to the receiver. This is usually sufficient for most locations if it is unrolled and laid on the floor or dropped out the window. Inside a steel constructed building it may be necessary to erect an outside antenna either up to the roof or on top of it. In localities where signal strengths are low as in rural districts, an outside antenna is always advisable with any radio receiver.

GROUND No ground is needed as set is grounded to the supply circuit internally.

ALIGNMENT PROCEDURE

Connect signal generator to control grid of first detector tube (6AG6) through a .05 MF condenser, and to chassis. Do not remove grid cap. Also connect output meter across speaker voice coil. Turn band switch to "American Programs" position. Turn condenser gang completely out of mesh.

Set signal generator at 465 K.C. and carefully adjust the four I.F. trimmers (located in top of I.F. coil cans) to point showing highest reading on output meter.

Leave band switch in "American Programs" position. Connect signal generator to antenna and ground terminals using a .0002 MF condenser in antenna lead.

Set signal generator and receiver dial both at 1700 K.C. Adjust B.C. OSC. trimmer until 1700 K.C. signal is heard.

Set signal generator at 1400 K.C. and turn condenser gang to the signal at 1400 K.C. Adjust antenna section and second section of preselector trimmers to point showing highest reading on output meter.

Set signal generator at 800 K.C. and rock pointer at 800 K.C. position on dial scale, while adjusting B.C. paddler, until combination is found which gives highest output reading. (Note: If there is noise level at 800 K.C., paddler can be adjusted to maximum noise without rocking gang and without use of signal generator. (Use short wire for pick-up if necessary.)

Turn band switch to "Police and Aircrat" position. Replace .0002 MF condenser in signal generator antenna lead with a 400 ohm carbon resistor.

Set signal generator and receiver dial both at 7.0 MC. Adjust POLICE OSC. trimmer until 7.0 MC signal is heard.

Set signal generator at 5.8 MC and turn condenser gang to signal at 5.8 MC. Adjust POLICE ANT. trimmer to point giving greatest output reading, while slightly rocking condenser gang.

Turn band switch to "Foreign Programs" position, still using 400 ohm carbon resistor in antenna lead to signal generator.

Set signal generator and receiver dial both at 22.0 MC. Adjust SW OSC. trimmer until 22.0 MC signal is heard.

Set signal generator at 18.7 MC. and turn condenser gang to signal at 18.7 MC. Adjust SW ANT. trimmer to point giving greatest output reading, while slightly rocking condenser gang.

Padders on "Police" and "Foreign" bands are fixed (no adjustment necessary).

 ALIGNMENT PROCEDURE**

Connect signal generator to control grid of first detector tube (6A8G) through a .05 MF. condenser, and to chassis. Do not remove grid cap. Also connect output meter across speaker voice coil. Turn band switch to "American Programs" position. Turn condenser gang completely out of mesh.

Set signal generator at 465 K.C. and carefully adjust the five I.F. trimmers (located in top of I.F. coil cans) to point showing highest reading on output meter.

Leave band switch in "American Programs" position. Connect signal generator to antenna and ground terminals using a .0002 MF condenser in antenna lead.

Set signal generator and receiver dial both at 1700 K.C. Adjust BC OSC. trimmer until 1700 K.C. signal is heard.

Set signal generator at 1400 K.C. and turn condenser gang to the signal at 1400 K.C. Adjust antenna section and second section of preselector trimmers to point showing highest reading on output meter.

Set signal generator at 600 K.C. and rock pointer at 600 K.C. position on dial scale, while adjusting BC paddler, until combination is found which gives highest output reading. (Note: If there is noise level at 600 K.C., paddler can be adjusted to maximum noise without rocking gang and without use of signal generator. Use short wire for pick-up if necessary.)

Turn band switch to "Police and Aircraif" position. Replace .0002 MF condenser in signal generator antenna lead with a 400 ohm carbon resistor.

Set signal generator and receiver dial both at 7.0 MC. Adjust POLICE OSC. trimmer until 7.0 MC signal is heard.

Set signal generator at 5.8 MC and turn condenser gang to the signal at 5.8 MC. Adjust POLICE ANT. trimmer to point giving greatest output reading, while slightly rocking condenser gang.

Turn band switch to "Foreign Programs" position still using 400 ohm carbon resistor in antenna lead to signal generator.

Set signal generator and receiver dial both at 22.0 MC. Adjust SW OSC. trimmer until 22.0 MC signal is heard.

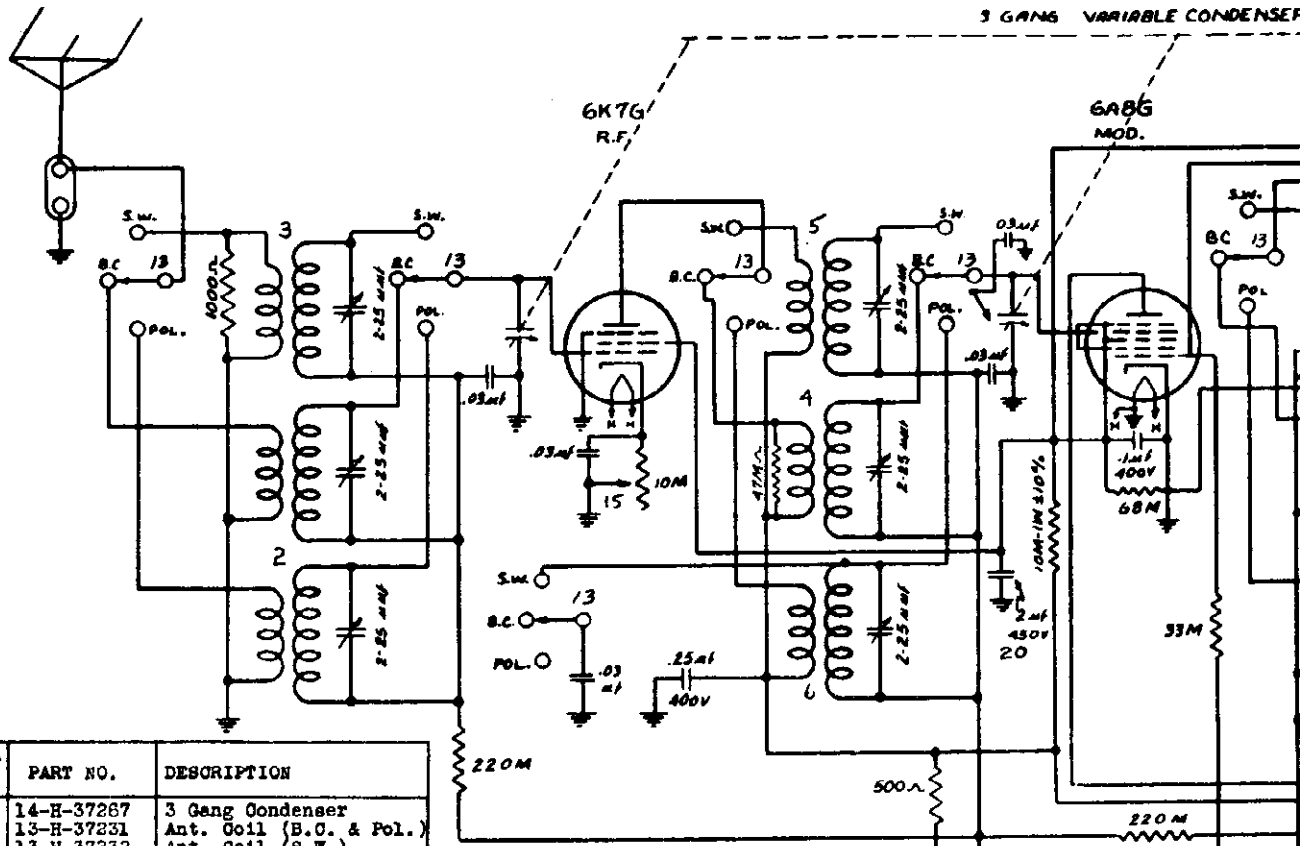

Set signal generator at 18.7 MC and turn condenser gang to the signal at 18.7 MC. Adjust SW ANT. trimmer to point giving greatest output reading, while slightly rocking condenser gang.

Padders on "Police" and "Foreign" bands are fixed (no adjustment necessary).

 Note C—15.0 V measured point C to ground on 50 V scale (see circuit diagram).
 All voltages, except rectifier filaments, measured from socket terminals indicated to chassis ground, using 1000 ohms per volt meter.

ALIGNMENT PROCEDURE

CHASSIS 10-1

1. Read alignment notes on Page 14.
2. Connect signal generator to control grid of first detector tube (6A9G) through a .05 MF. condenser and to chassis. Do not remove grid cap. Also connect output meter across speaker voice coil. Turn band switch to "American Programs" position. Turn condenser gang completely out of mesh.
3. Set signal generator at 465 K.C. and carefully adjust the five IF trimmers (located in top of IF coil cans) to point showing highest reading on output meter.
4. Leave band switch in "American Programs" position. Connect signal generator to antenna and ground terminals, using a .0002 MF condenser in antenna lead. Adjust BC OSC. trimmer until 1700 K.C. signal is heard.
5. Set signal generator at 1400 K.C. and turn condenser gang to the signal at 1400 K.C. Adjust BC ANT. and BC RF trimmers to point showing highest reading on output meter.
6. Set signal generator at 800 K.C. and rock pointer at 800 K.C. position on dial scale, while adjusting BC paddler, until combination is found which gives highest output reading. (Note: If there is noise level at 800 K.C., paddler can be adjusted to maximum noise without rocking gang and, without use of signal generator. (Use short wire for pick-up if necessary.)
7. Turn band switch to "Police and Aircraft" position. Replace .0002 M.F. condenser in signal generator lead with a 400 ohm carbon resistor.
8. Set signal generator and receiver dial both at 7.0 MC. Adjust POLICE OSC. trimmer until 7.0 MC signal is heard.
9. Set signal generator and receiver dial both at 22.0 MC. Adjust SW OSC. trimmer until 22.0 MC signal is heard.
10. Set signal generator at 5.8 MC and turn condenser gang to signal at 5.8 MC. Adjust POLICE ANT. and POLICE RF trimmers to point giving greatest output reading, while slightly rocking condenser gang.
11. Turn band switch to "Foreign Programs" position, still using 400 ohm carbon resistor in antenna lead to signal generator.
12. Set signal generator and receiver dial both at 22.0 MC. Adjust SW OSC. trimmer until 22.0 MC signal is heard.
13. Set signal generator at 18.7 MC and turn condenser gang to the signal at 18.7 MC. Adjust SW ANT. and SW RF trimmers to point giving greatest output reading, while slightly rocking condenser gang.
14. Padders on "Police" and "Foreign" bands are fixed. (No adjustment necessary).

NOTE: IF Sensitivity at 465 K.C. is 90 microvolts for 50 milliwatts output
 Ant. Sensitivity at 800 K.C. is 1 microvolt for 50 milliwatts output

Notes

GALVIN MFG. CO.

ions to correct for the acoustic differences in the various makes of cars give a pleasing effect to any type of program that anyone might prefer.

The three steps of the sensitivity switch controlled by the left hand knob are:

Country; average sensitivity 1.5 Microvolts for 1 Watt.

City; average sensitivity 5 Microvolts for 1 Watt.

Street Car; average sensitivity 15 Microvolts for 1 Watt.

"High Fidelity" is a term applied to an audio system that reproduces all frequencies of the audible spectrum at the same level of output.

The human ear however is most sensitive to frequencies in the middle register occupied by the human voice. The acoustics of the average automobile tend to accentuate this effect. The actual effect to the ear then of "High Fidelity" is that the pleasing higher and lower frequencies of music are dropped into the background and tends to spotlight the human voice as shown on the chart in Fig. (1).

This is the condition that occurs when the right hand knob of the acoustinator is set at "Voice" position.

Fig. 4

A beautifully pleasing and lifelike effect would be given to any musical program if we would compensate for the limitations of the ear and in some manner drop the center portion of the audio register slightly below the level of the two ends. The deep bass notes and high notes that give expression to music would then stand out in a very natural manner. This has been done by means of an electrical filter network that is switched into the circuit when we turn to the "Music" position. Fig. (1).

Fig. 1

RELATIVE AFFECT TO THE EAR EXPRESSED IN PERCENTAGE OF THREE ACCOUSTINATOR POSITIONS IN AVERAGE AUTOMOBILE

Many people prefer the deep bass instruments that mark the rhythm of music to be accentuated above all others. A soft mellowness is given music when this is done and the sound of static and non-made electrical interference which is reproduced at a very high audio frequency is reduced to a minimum when the acoustinator is set to the bass position.

Many combinations of positions then of right and left knobs are available to give us the finest reception regardless of the demands of the region through which we are driving and regardless of the tonal balance required of the program to which we may be listening.

THE 1937 IMPROVED MAGIC ELIMINODE

The 1937 Magic Eliminode consists of filters in the various supply leads to the radio set to prevent the introduction of "motor noise" at these points and an improved bucking or balancing circuit in Models 65, 70, and Golden Voice which may be adjusted to prevent the development of "motor noise" in the antenna circuit.

The manner in which the cancellation of "motor noise" in the antenna circuit is accomplished is as follows:

Developed on the antenna coil, from the antenna system we have both "motor noise" and "broadcast signal". Developed on the "A" lead of the radio set which is connected into the electrical system we have "motor noise" alone. We introduce "motor noise" into the antenna circuit from the "A" lead in opposite phase to that picked up by the antenna.

We then vary the intensity introduced from the "A" circuit into the antenna coil by means of the shifter between the two circuits, until the intensity from both antenna system and "A" circuit is the same. When this is accomplished there is cancellation of "motor noise" in the antenna system and the broadcast signal comes through without being affected in any way.

For those cases in which the motor noise developed in the "A" circuit is in phase with that of the antenna system, provision is made to reverse the phase of the coupling coil to the antenna circuit so that bucking action may occur. Refer to Fig. (2).

MAGIC ELIMINODE BALANCING PROCEDURE

After the set is completely installed, if any ignition noise is present with the shifter in a closed position and with the "A" lead plugged into the bottom of the set it will be necessary to use the balance.

To use the balance, pull the end of the fused "A" lead out of the bottom of the set No. 1 (Fig. 2) and plug it into the balance terminal receptacle No. 3 (Fig. 2). Take the short heavy jumper with pin prongs on either end and plug one end into receptacle No. 1 (Fig. 2) on the bottom of the set and plug the other end into balance terminal receptacle No. 2 (Fig. 2). Turn the set then to the point on the dial where the noise appears with greatest intensity.

Adjust the eliminode shifter wheel by revolving it with the thumb as shown in (Fig. 2) until the motor noise disappears.

If it is found when turning the shifter toward an open position that the noise gradually becomes louder without any sign of decrease at any point, it will be necessary to reverse the connections in receptacles No. 2 and No. 3 (Fig. 2). Then readjust the shifter wheel with the thumb as described above.

When this adjustment is once made, it will not change unless some change is later made in the car wiring or the radio set is installed in another car.

CHASSIS PICKUP

In extreme cases of "motor noise" in the Models No. 65, 70 and Golden Voice, a preliminary test for chassis pickup should be made before attempting to balance on antenna interference.

When making this test, it is necessary to use a well shielded dummy antenna plugged into the set in place of the regular antenna lead-in. The dummy antenna can be made by using a standard Motorola antenna series condenser, part M-94, and short circuiting the inside connection to the shell.

Balance the antenna trimmer very carefully to this dummy antenna so that the set is at maximum sensitivity and then run the car.

Should "motor noise" occur after this test, it will be entering the radio set through some other source than the antenna.

ACCOUSTINATOR

The Acoustinator used on the 1937 MOTOROLA must be mounted always at a point most convenient to the customer since its operation is just as essential as the tuning dial or the volume control in giving complete enjoyment and maximum performance from the radio set.

The Acoustinator performs the function of varying the sensitivity of the radio set in three logical predetermined steps from the extreme sensitivity necessary in isolated communities to the noise free smooth reception desired in Metropolitan areas, and changes the tone characteristics in three distinctly different post-

MODEL 6C1
Schematic
Data

I.F. 175 KC.

JANUARY 1937

IF the total capacity of the antenna and shielded lead is approximately 200 mmf., which would be the case in a running board or ordinary roof antenna (not metal roof), insert the antenna plug with the mark on the HC side—See Fig. 3.

If the total capacity of the antenna and shielded lead is approximately 70 mmf., such as may be the case if a "fish pole" antenna is used, insert the antenna plug with the mark on the LC side.

Fig. 3—Antenna Plug Insertion

MODEL 6C1
Alignment, Coils

GAMBLE-SKOGMO, INC.

Voltage, Socket
Trimmers

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the R.F. interstage section of the tuning condenser. (See Fig. 2 for location of this section.)

Connect the ground lead of the signal generator to the chassis. The chassis should be in the case.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 2.

1581 KC Adjustment

Set the signal generator for 1581 KC.

Turn the rotor of the tuning condenser to the full open position.

Insert the antenna plug with the mark on the high capacity (HC) side. Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 2 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the R.F. interstage and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Tune in this signal and adjust the 600 KC antenna trimmer to maximum (See Fig. 3 for location of this trimmer).

After the alignment procedure is completed, the antenna plug may be withdrawn and reinserted on the LC side if a low capacity (70 mmf.) car antenna is used.

Adjusting Antenna 600 KC Trimmer

After the radio is installed and the car antenna is connected, it will be necessary to readjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 3 for location of this trimmer.

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Hold the tuning knob. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received.

A very short insulated screwdriver will be helpful.

Fig. 3—Location of Tubes and Vibrator

Polarity in inserting the vibrator must be observed. It can be inserted in two ways, and the correct method depends on which terminal of the car storage battery is grounded. Full instructions are on the vibrator.

Fig. 7—Various Control Head Mountings

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. (See Fig. 3 for location of this section.)

Connect the ground lead of the signal generator to the chassis. The chassis should be in the case.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 3.

1581 KC Adjustment

Set the signal generator for 1581 KC.

Turn the rotor of the tuning condenser to the full open position.

Insert the antenna plug with the mark on the high capacity (HC) side. Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 3 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Tune in this signal and adjust the 600 KC antenna trimmer to maximum. (See Fig. 5 for location of this trimmer).

After the alignment procedure is completed, the antenna plug may be withdrawn and reinserted on the LC side if a low capacity (70 mmf.) car antenna is used.

Adjusting Antenna 600 KC Trimmer

After the radio is installed and the car antenna is connected, it will be necessary to readjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 5 for location of this trimmer.

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Hold the tuning knob. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received

Inserting Antenna Plug

IMPORTANT—The antenna plug can be inserted in two ways depending on whether the antenna is of high or low capacity.

If the total capacity of the antenna and shielded lead is approximately 200 mmf., which would be the case in a running board or ordinary roof antenna (not metal roof), insert the antenna plug with the mark on the HC side—See Fig. 5.

If the total capacity of the antenna and shielded lead is approximately 70 mmf., such as may be the case if a "fish pole" antenna is used, insert the antenna plug with the mark on the LC side.

The 1936 Chrysler Motors cars (except Plymouth—but including Chrysler, Dodge and DeSoto) have a steel roof, separated from the body proper, which is used as an antenna. The capacity of these antennas is about 1700 mmf. If this radio is installed in these cars, it will be necessary to use a running board or "fish pole" antenna.

Most 1937 General Motors cars are equipped with an antenna built into the running board which is insulated from the body proper.

If a running board or under-car antenna is used, it must be one which is covered with a suitable insulation, to prevent short circuiting in wet weather.

Changes in Later Models

The "B" and later issues of this series have changes incorporated in them as explained in this article. The issue letter is a large letter stamped on the chassis base.

The "B" and later issue models are different from the "A" issue models in the following respects: The antenna, interstage and oscillator assemblies have been redesigned; condensers C13, 21, 22, and 32 have been changed to a different type with a new part number; the value of condenser C8 has been changed from 70 mmf. to 35 mmf.; condenser C35, 250 mmf., has been added to the circuit. On radios with the

Roof Speaker and Dual Speakers**(1936 Cars)**

The Ford and General Motors 1936 automobiles have provision for mounting a speaker in the car roof (Ford 5¼ inch speaker, General Motors 5¼ or 8 inch speaker). This radio is so designed that roof speaker installations in these cars can readily be made.

Five types of speaker installations can be made as follows:

- Single 6 inch Speaker on Chassis Case Cover
- Single 5¼ inch Roof Speaker
- Single 8 inch Roof Speaker
- Dual 5¼ inch Roof and 6 inch Chassis Speakers
- Dual 8 inch Roof and 6 inch Chassis Speakers.

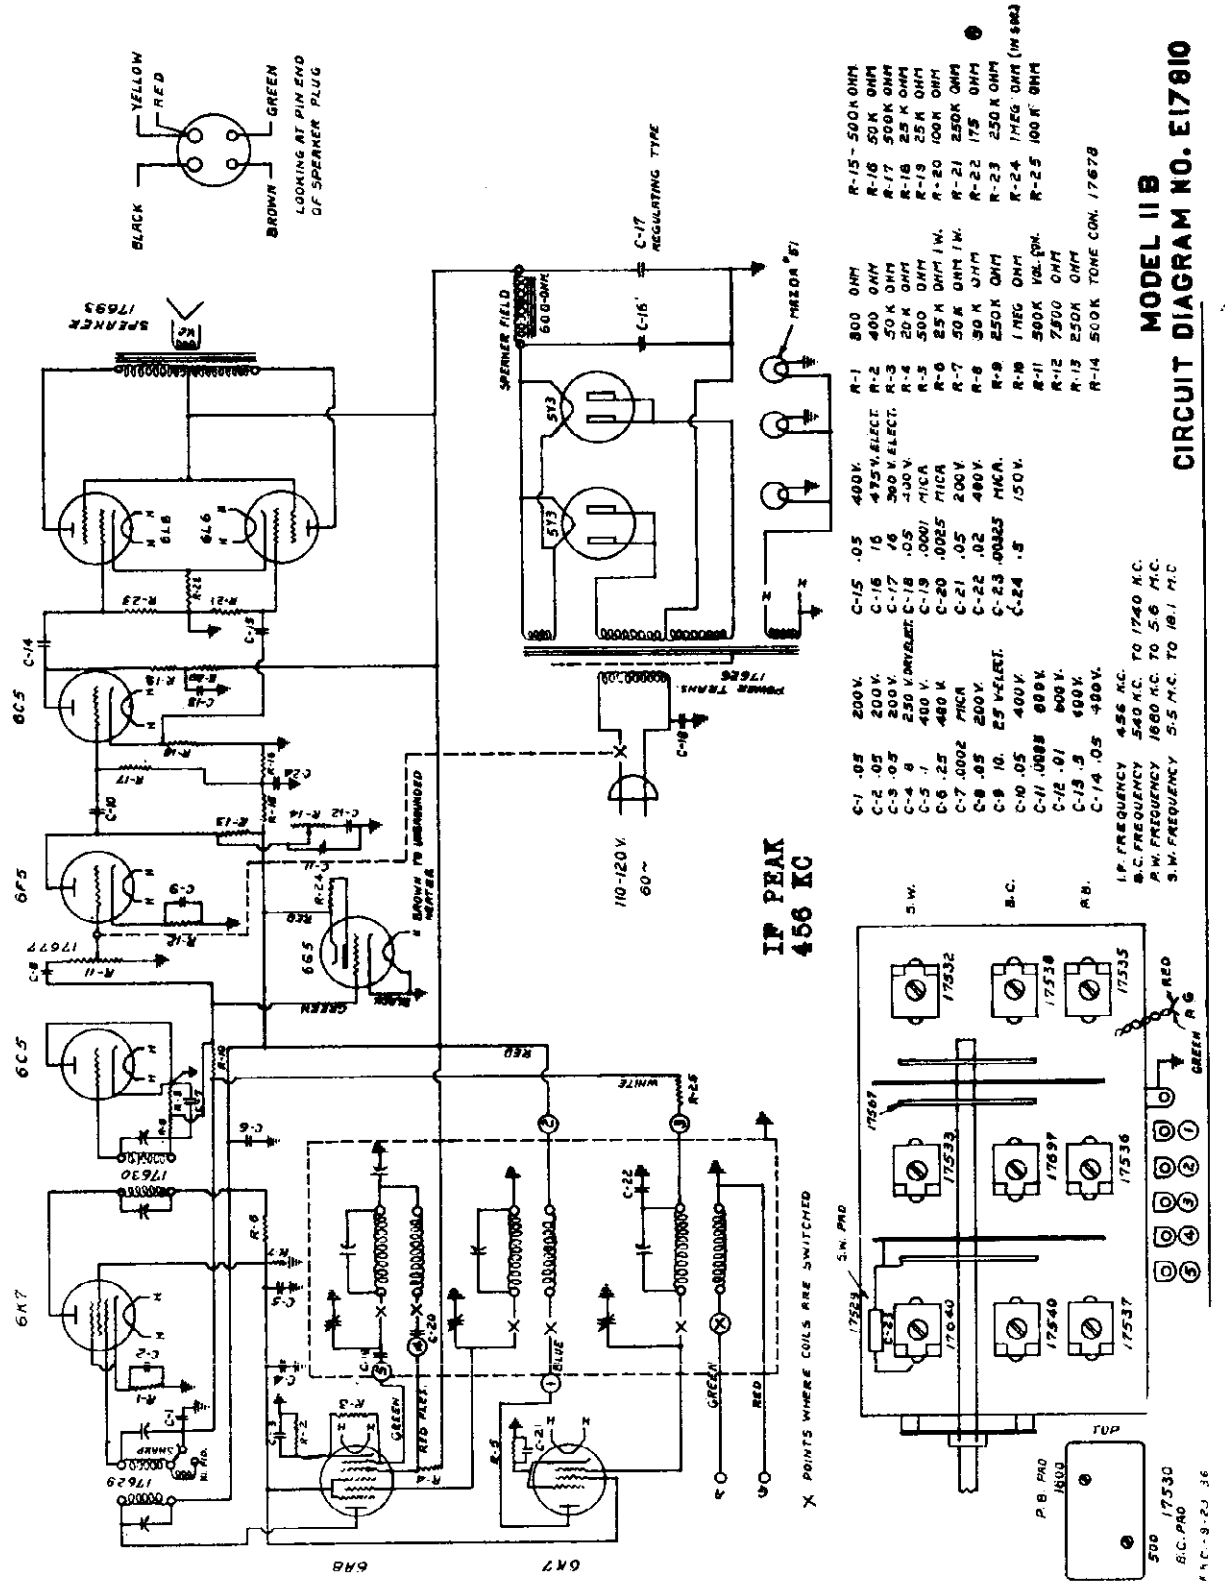

The electrical connections of the different speaker installations are shown in the schematics—Figs. 1 and 2.

Complete information regarding the method of making the installations is in the installation manual packed with each radio. The kits of parts required are listed in the installation manual and in the parts list at the back of this manual.

MODEL 11B

Alignment
Voltage, Data

GAMBLE-SKOGMO, INC.

IF ALIGNMENT. If all parts and tubes check OK and sensitivity is low on all bands it is probably due to IF being out of adjustment. It is necessary to use a test oscillator or signal generator having accurate calibration and positive attenuation. Proceed as follows:

IF ALIGNMENT. Put wave switch in B. C. position, tone control in normal (not high fidelity), open tuning condenser, connect signal generator to Grid of 6-A-8 tube leaving present cap in place. A small condenser .002-.01 should be used in series with the signal generator lead. Set the signal generator at exactly 456 K. C. and adjust the trimmers in the top of the IF cans, going over them several times and reducing the output of the signal generator as the sensitivity increases, do not reduce by the volume control on the set. The 6-G-5 "Eye" may be watched to indicate "peak" or an output meter may be used, connected across the speaker.

HIGH FREQUENCY ALIGNMENT. This should not be changed unless all other possible defects are eliminated and the set still does not perform properly.

BROADCAST: Connect signal generator to Ant. post thru .0002 condenser. Trim oscillator at 1750 K. C. and pad at 535 K. C. See drawing on circuit diagram for location of trimmer and padding condensers. Trim B. C. Ant. and R. F. coils at 1400 K. C.

POLICE BAND. Trim oscillator at 5.6 M. C. and pad at 1.7 M. C. Trim Ant. and R. F. coils at 4.5 M. C.

SHORT WAVE. Use 400 ohms in series with the signal generator. Trim oscillator at 18 M. C. The pad is fixed so that the low frequency end point is approximately 5.5 M. C. Care should be taken to be sure that the oscillator is trimmed for reception of the fundamental frequency. With the tuning condenser set at the high frequency end, and the signal generator set at 18 M. C., two settings of the oscillator trimmer will be found to give response—one fairly tight and the other, loose—the loose one is the correct setting.

Trim the ant. and R. F. coils on 15 M. C., retuning the tuning condenser to compensate for reaction on the oscillator.

TUNING BELT SLIPPING: Usually due to:

1. Idler spring too loose.
2. Belt worn or stretched.
3. Condenser thrust bearing too tight or not lubricated.
4. Defective gear on condenser.

If the belt only slips slightly it can usually be remedied by applying a small amount of "belt dressing" such as used in machine shops, to the belt while the knob is turned through the entire range. Care should be used to not get too heavy a coating which will build up the pulleys. Idler spring tension may be increased by cutting off about one quarter inch of the spring and forming a new loop on the end. A worn or badly stretched belt should of course be replaced. A tight thrust bearing should be very carefully adjusted, usually one eighth turn to the left on the adjusting screw will be sufficient. A gear may stick due to dirt in the teeth, but if a tooth is damaged, the gear should be replaced, making sure that the floating gear is turned about two "teeth" against the spring to eliminate back lash.

REPLACING DIAL SCALE. Should the dial scale be broken in shipment, or for any reason need to be replaced, care should be taken to see that: the plate that holds the glass is not bent, that the glass lays "flat" on the plate, that there is clearance around the pointer shaft, and that rubber bands are in place on the hold down clamps.

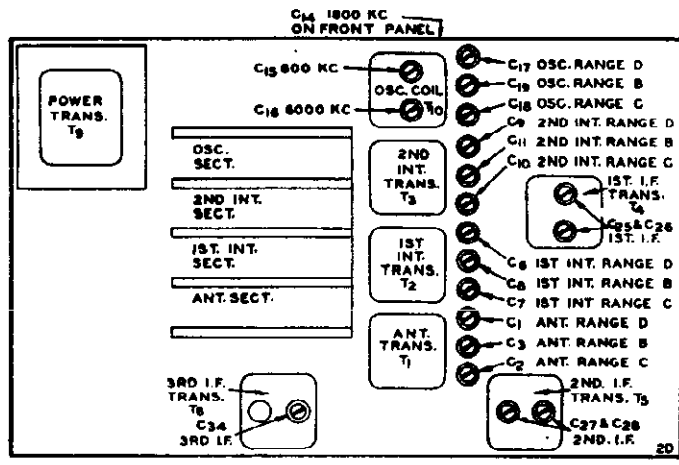

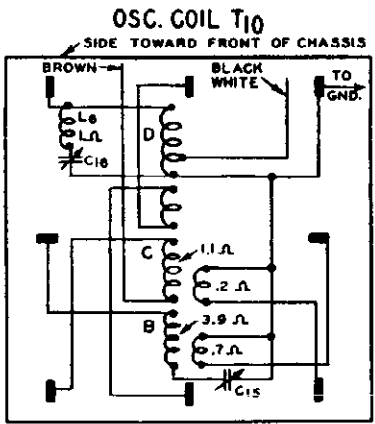

Fig. 3—Location of Trimmers

GAMBLE-SKOGMO, INC.

MODEL 42DL670 Alignment, Voltage Notes

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch should be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the diode return circuit at the volume control. This is done by removing the wire connecting condenser C42 to resistors R15, R19 and R22, at the terminal strip located near the back of the planetary drive. Cut this wire to correct length and solder it to the proper terminal on the phono switch—See Fig. 7, keeping the wire close to the back of the chassis base.

A wire is then connected from the lug on the above mentioned terminal strip to which C42 was connected, to the correct terminal on the phono switch—See Fig. 7. This wire should be brought directly to the back of the chassis at a point close to the phono jack pin tip nearest the channel provided for a chassis mounting bolt, and then routed over to the switch.

Complete the other connections as illustrated in Fig. 7.

It will be necessary to retrace the AC line cord away from the 6C3 1st audio grid lead by running it between the volume control and the filter choke and then straight back to the hole provided for it in the chassis base.

If a hum is heard when the phono pickup is touched, reverse the two pickup leads.

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-210 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

(5) A.C. voltage as read across heater terminals 4 and 5.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. To other side of the single trimmer it then connects to the grid lead, using a piece of heavy wire in order to support the trimmer. The lead to the replacing trimmer be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft.

If the nut on the back end of this assembly is too tight, the drive will be very hard to turn and in high speed. If the condenser rotates back off this nut one or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and gears to see if they are running properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 1900 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 1000 less 917 KC, or 4083 KC. It may be necessary to increase the input signal to hear the image.

5000 KC Adjustment

Set the signal generator for 5000 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (four short wave band).

Adjust the oscillator Range C trimmer (C18) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 9000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd intermediate Range C trimmers (C7 and C10) and antenna Range C trimmer (C2) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment

Set the signal generator for 1800 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd intermediate Range D trimmers (C6 and C9) and antenna Range D trimmer (C1) to maximum.

When adjusting the 2nd intermediate Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

I. F. Adjustment

Set the signal generator for a signal of 416 KC. Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the leveling off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these controls are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 mf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

In sets using potentiometers, loosen the screw of the large potentiometer, then turn it to the 1500 KC mark on the standard wave band scale. Retighten the screw.

In sets using the moving beam of light, there is moving light assembly held to the front of the drive drum of the frequency counter. Loosen this screw and move the light to the 1500 KC mark on the dial. Retighten the screw.

Adjust the 1st and 2nd intermediate Range B trimmers (C8 and C11) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

NOTE: RESISTANCE VALUES NOT SHOWN ARE SMALL.
Fig. 4—R. F. and Oscillator Coil Base Terminal Arrangement and D. C. Resistance of Windings

1800 KC Adjustment
Set the signal generator for 1800 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth, at the same time adjusting the 1800 KC trimmer, until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

18,300 KC Adjustment
Set the signal generator for 18,300 KC. Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator. Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range D position (2nd short wave band). Adjust the oscillator Range D trimmer (C12) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment
Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the interstage Range D trimmer (C8) and antenna Range D trimmer (C2) to maximum. When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained. Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment
Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

antenna Range B trimmer (C4) to maximum.
Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment
Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth, at the same time adjusting the 600 KC trimmer, until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range B Alignment
After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

Range C Alignment
CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 plus 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

5800 KC Adjustment
Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator. Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range C position (1st short wave band). Adjust the oscillator Range C trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment
Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the interstage Range C trimmer (C9) and antenna Range C trimmer (C3) to maximum. Do not change the setting of the oscillator Range C trimmer.

I. F. Adjustment
Set the signal generator for a signal of 475 KC. Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator. Turn the band selector to the Range B position (standard wave band). Turn the selectivity control to the sharp position and keep it in this position for all adjustments. Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC. Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Twenty-five Cycle Receivers
Set the signal generator for 1750 KC. Turn the rotor of the tuning condenser to the full open position. Keep the band selector in the standard wave position. Connect the antenna lead of the receiver through a 200 mf. condenser to the output of the signal generator. For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action. Adjust the oscillator Range B trimmer (C18) until maximum output is obtained. The location of this trimmer is shown in Fig. 3. **1500 KC Adjustment**
Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw. Adjust the interstage Range B trimmer (C10) and

7 TUBE - 2 BAND

32 VOLT D.C. RADIO

OCTOBER 1936

ALIGNMENT & NOTES

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector (G₁).

Connect the ground lead of the radio to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the radio through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

Adjust the interstage Range B trimmer (C10) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C30) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC., or 14,088 KC. It may be necessary to increase the input signal to hear the image.

ary to increase the input signal to hear the image.

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Connect the antenna lead of the radio through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

Adjust the oscillator Range D trimmer (C31) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C1) to maximum. When adjusting these trimmers, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC (C28) trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Antenna and Ground

Run the antenna at right angles to any 32 volt lines and keep it as far away from these lines as possible, in order to avoid line noise being carried into the radio via the antenna.

A ground connection may be obtained by connecting to a water pipe, a pipe driven in the ground, or the metal jacket of a water pump. Do not ground the receiver to the 32 volt system conduit or fittings at any point.

CAUTION—Read the Following

To avoid the danger of damage to the radio and accidental short circuit, the following facts should be understood.

The metal chassis is connected to one side of the line—See Fig. 2. 32 volt lines are generally grounded on one side—either side may be used. If the side of the line, not connected to the metal chassis, is grounded and the metal chassis comes in contact with the external ground, the line will be short circuited and an excessive current may result.

In any service work, therefore, on this chassis keep it on a wood or other insulated surface. Disconnect the antenna and ground leads to avoid the possibility of any external ground contacts with the chassis. The person working on the set should avoid coming in contact with any ground.

32 Volt Power Supply

Polarity of Power Supply

There is a red mark on the plug at the end of the power supply cord of the radio. The prong of the plug at which the red mark is placed must be plugged into the positive side of the line.

Use a receptacle on the 32 volt line from which the plug will not have to be removed after it has once been inserted correctly.

If the polarity of the line is not known, that is, if it is not known which side of the line is positive, a meter may be used to indicate the polarity. A voltmeter of 50 volt range or up is used. Connect the meter across the line. If the pointer deflects correctly, then the positive post of the meter is connected to the positive side of the line.

If the polarity of the line is not known and there is no way of determining it, insert the power supply plug, turn on the set, advance the volume control and proceed to tune the radio. If no sounds are heard from the speaker after the plug has been in two minutes, withdraw the plug, turn it around and re-insert it. This time sounds should be heard after the tubes have been heated.

Caution

If used on any other type of power supply than 32 volt DC, severe damage may be done to the receiver.

Do not turn the radio on unless all of the tubes and the dial lamps are in the proper sockets. Use only No. 51 bayonet pin base lamps.

Do not leave the plug inserted for more than five minutes if it is found that the radio does not operate.

Line Voltage Range

The radio will operate satisfactorily within a line voltage range of 25 to 42 volts.

Series Resistor

If the line voltage is higher than 42, it will be necessary to use a series resistor to cut it down. If the voltage varies, a variable resistor may be required.

Starting Current

When first turned on, the drain for a few seconds is slightly higher than normal until the tubes heat up. Some automatic plants are adjusted to start under a load of 200 to 300 watts. If a number of devices such as lights or motors are being used and the radio set is turned on the total drain may be sufficient to start the plant.

Eliminating Ignition and Generator Noise

After the radio is in working order, the following procedure must be followed in practically all cases to eliminate ignition and generator noise caused by the charging plant. If the charging plant causes no noise, then of course, these steps do not have to be taken.

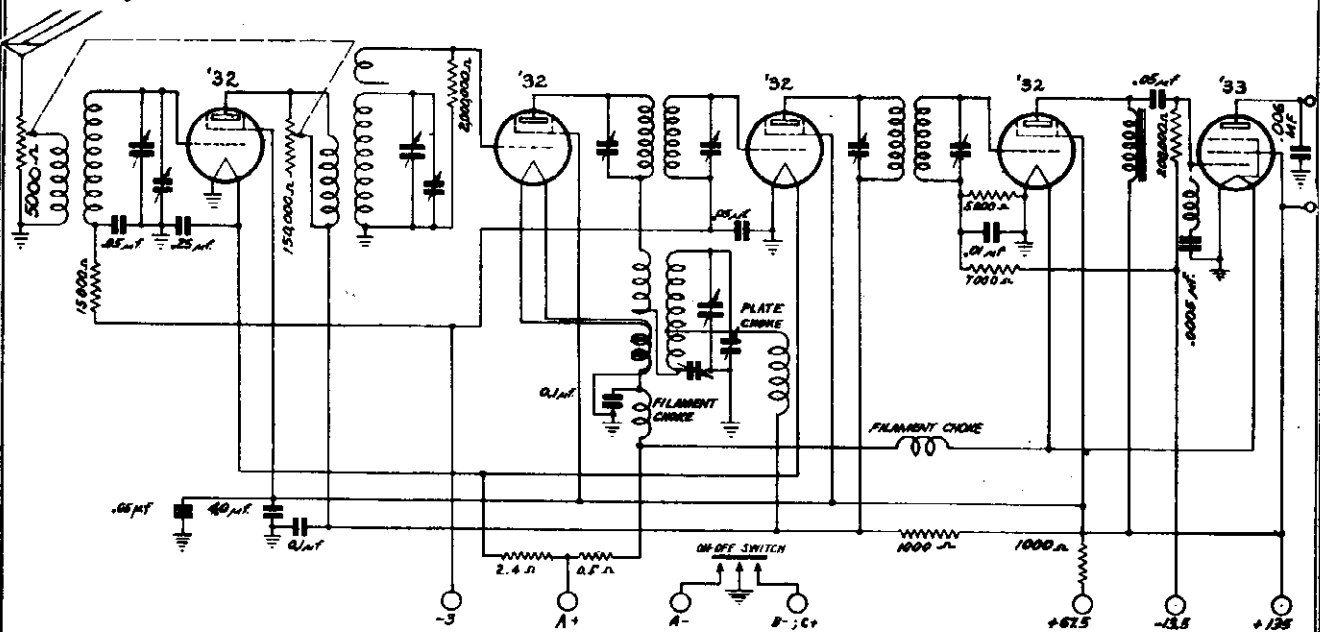

One spark plug suppressor must be placed on each spark plug of the engine. One spark plug for example would be required on a one-cylinder engine and four must be used on a four-cylinder engine. To connect the spark plug suppressor, remove the wire from the top of the plug, put the suppressor on and attach the wire to the other end of the suppressor.

A generator condenser must be used. This consists of two .5 mf. sections in one unit. The two sections have one side grounded to the metal case of the condenser. Mount the condenser on the frame of the charging plant. This will ground it. Then connect the two leads to the charging switch, one on each side of the line.

In some large installations, where the charging unit is on only two or three times a week, the above steps do not have to be taken as interference is caused only when the generating plant is in operation.

CONVENTIONAL ALIGNMENT - SEE SPECIAL SECTION

IF PEAK 175 KC

Circuit

This chassis has one stage of radio frequency amplification, a combined detector and oscillator, one stage of intermediate frequency amplification, a second detector, and one stage of audio frequency amplification. The intermediate stage operates at a frequency of 175 K.C. All stages are transformer coupled with the exception of the audio stage which is coupled to the detector by a choke, condenser and resistor network.

The plate choke in the oscillator circuit has been substituted for the 15,000 ohm resistor to allow wider limits on the tube used in this circuit.

The complete chassis is mounted on rubber to prevent any vibration being transmitted to the tubes.

Tubes

Type '32 tubes are used in the R.F., 1st detector, intermediate, and second detector stages. The audio output tube is a type '33 pentode.

Please specify to change without notice.

control electrode. When the signal is tuned to resonance, practically no plate current flows and the voltage of the control electrode is the same as that of the target. There is no opposition to the flow of electrons to the target. Tuning of resonance decreases the control electrode voltage and causes the distorted sector of the target to widen, because of the opposition to the flow of electrons in the direction of the control electrode.

Referring to the 1st I.F. transformer T3 in Fig. 2, it will be noted that there is a coupling winding shown below the primary.

When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity; also, the plate of the audio section of the 6B7 tube is bypassed by condenser C17.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a wide greatly softened resonance curve. Passage of a wide range of audio frequencies is thus obtained. Condenser C17 is connected in this position to avoid bypassing the higher audio frequencies.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. Turn the band switch to the Range D position (short wave band).
Adjust the oscillator Range D trimmer (C13) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.
Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C3) to maximum.
When adjusting the interstage and antenna Range D trimmers it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 15,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator rotor, wave trimmer, the 15,000 KC adjustment must be repeated.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.
Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Twenty-five Cycle Models
The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 117-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

General Data
The models with the tuning indicator tube are wired as shown in the schematic. This tube contains a triode and cathode ray section in one envelope.

The cathode ray is produced by the attraction of electrons from the upper end of the cathode to the coated target or anode which is operated at a high positive potential. When this electron stream strikes the target the coating glows. The electron stream is controlled by an additional element, or control electrode, in the tube.

As a signal is tuned in, the control grid of the triode section of the 6C5 cathode ray tube becomes increasingly negative, the negative bias voltage is taken from the AVC line. The AVC voltage is reduced to a suitable value by the voltage divider arrangement of the 8 megohm resistors. The increased bias voltage reduces the triode plate current. This reduces the voltage drop across the 1 megohm plate resistor and raises the triode plate voltage. The triode plate is connected to the control electrode of the cathode ray section of the tube.

The shape and size of the area on the target struck by the cathode ray is governed by the voltage of the

I. F. Adjustment
Set the signal generator for a signal of 456 KC.
Connect the output of the signal generator through a .1 microfarad capacitor to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.
Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.
Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.
Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the adjustment of each range, as explained below, is completed, it is advisable to repeat the procedure on a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.
Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.
Connect the antenna lead of the receiver through a 200 microfarad capacitor to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C17) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment
Set the signal generator for 1500 KC.
Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

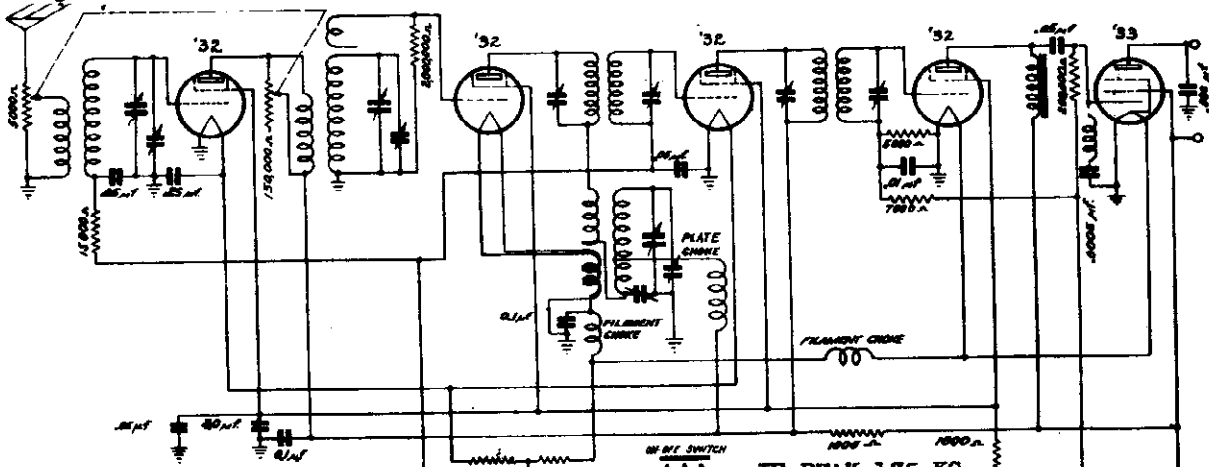

Adjust the interstage Range B trimmer (C10) and antenna Range B trimmer (C3) to maximum.
Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment
Set the signal generator for 600 KC.
Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment
Set the signal generator for 18,100 KC.
As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.
Turn the rotor of the tuning condenser to the full open position.

*This includes filament voltage.

**250 v. Scale.

The measurement of grid bias voltages is not recommended as this causes an abnormal rise in plate current which is injurious to the tube. When the receiver does not function properly and the trouble is apparently due to incorrect grid bias on any tube or tubes, the cause of the incorrect bias may be determined by applying the proper continuity test.

CAUTION: Do not attempt to take voltage measurements or test the '33 pentode tube with a set analyzer which is not designed to test that type of tube. A special adaptor is necessary. The latest type analyzers only are designed to test pentode tubes. The UY socket in an analyzer which is used to test '24, '35, and '27 tubes cannot be used to test '33 pentode tubes. A break-in adaptor and the external binding posts of the set analyzer may be used to take voltage measurements when an adaptor is not available.

Comparison of the voltage measurements taken and those shown in the chart below will show any irregularities. The cause of any variation may be determined by applying the proper continuity test. **REMEMBER**—Voltage measurements will vary slightly with different sets of tubes, and also with different chassis. Unless the voltages are radically different than normal, they may be considered satisfactory.

The voltages shown in the chart were taken with a 1000 ohm per volt voltmeter; voltage measurements taken with a voltmeter having a different resistance will, of course, differ from those shown.

The .006 mfd. condenser connected from the plate of the pentode tube to ground is there for two reasons,—one, to prevent any I.F. or harmonic of the intermediate frequency from getting into the speaker and possibly coupling back into the antenna to cause a squeal; two, to put the proper amount of capacity across the speaker winding to produce a pleasing tone quality. This condenser may be varied in any value from .002 mfd. to .006 mfd. without losing its effectiveness in preventing the I.F. from getting into the speaker.

This receiver should be connected ONLY to an electric light outlet supplying current of 110 to 120 volts, 50 to 60 cycle A.C. If connected to any other type of current or voltage, the set may be seriously damaged. If you are in doubt as to the type of current available, your electric power company will be glad to furnish the needed information.

WARNING—This receiver can be operated only on 105-120 volt, A. C., 50-60 cycle. This is the current commonly supplied, although a few communities or neighborhoods are supplied with 25-30 cycle or with D.C. The receiver may be badly damaged if it is connected to incorrect supply. If there is any doubt whether your supply is proper for this receiver, your local electric company can advise you.

105-115 volts alternating current 50-60 cycles - 60 watts.
GREEN (broadcast band) 530 - 1650 Kilocycles
RED (short wave band) 1650 - 14,000 Kilocycles

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:
To peak I.F. transformers connect oscillator (set at 466 KC) to grid of 2A7 tube and (black) ground at minimum capacity. With variable condenser set at minimum capacity, (extreme left of its rotation) adjust four trimmers (one nut and one screw on each transformer trimmer) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
To align Broadcast band, set wave changing switch to Green (right turn) and with variable condenser at minimum capacity disconnect antenna wire and connect 1550 KC oscillator to antenna coil in series with a 75 MFD condenser. Adjust oscillator (front) section trimmer to resonance. Set oscillator to 1400 KC, rotate variable condenser until signal is tuned in, then adjust R.F. (rear) section trimmer to resonance. Check output at 1200, 1000, 800, and 600 Kilocycles if necessary bend plates (of rear k.f. section of variable only).
To align Short wave band, set wave changing switch to RED (left turn) and with input oscillator connected as above and set at 1720 KC, tune in signal, adjust padding condenser on rear of chassis to resonance. Check for output at 1650 KC and at harmonics of 1000 KC (2000 KC), of 1200 KC (2400 KC), of 1400 KC (2800 KC), and of 1720 KC (3440 KC). DO NOT BEND PLATES.
For failure to operate over both bands check 2A7 tube and connections to and contacts of wave changing switch.

BATTERY RADIO

ALIGNMENT. IF and Broadcast alignment same as Model 11-B. For IF, connect signal generator to grid of 1-C-6 tube, be sure tuning condenser is open.

CODE INTERFERENCE. This may be noticeable in regions close to the Great Lakes and is due to shore radiotelegraph service being received directly on the IF amplifier and usually comes in regardless of tuning. All late production of this model going into Great Lakes territory were equipped with a wave trap which greatly reduces such interference. Such sets had the letter "T" marked on back of chassis and on carton. This wave trap No. 17736 may be added to any other production sets as shown in the circuit diagram. After installation it must be tuned to minimum response to a 456 signal applied to the antenna lead or to minimum reception of the code interference.

MODEL 740

GAMBLE-SKOGMO, INC.

Alignment
Trimmers**SERVICE NOTES:**

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-106 Output I.F. Transformer

Part No. 108-105 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

- With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-106) to resonance.
 - With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6AG6 and adjust input I.F. transformer (No. 108-105) to resonance.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

- With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
 - Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3.)
 - Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)

- Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

- With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
 - Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
 - Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

- With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
 - Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
 - Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
 - Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.
 - Recheck broadcast band alignment.

ALIGNMENT PROCEDURE

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

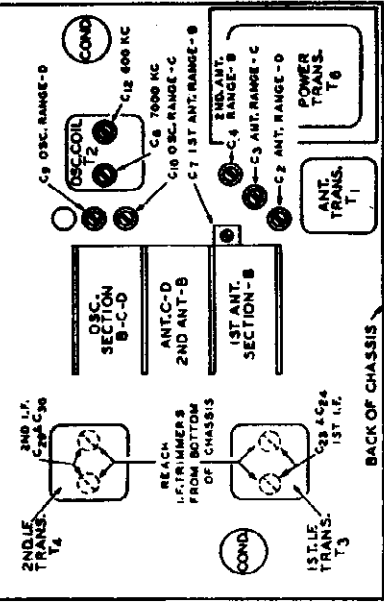

Fig. 3—Location of Trimmers

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.
After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

MODEL 762
Circuit Data
Notes, Parts

GAMBLE-SKOGMO, INC.

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna coil assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils and D respectively are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. When it is in the Range B position, a double tuned antenna R.F. stage is used while for the C and D Ranges, a single tuned secondary is used.

A type 6J7 tube functions as the 1st detector. A separate type 6G5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

Fig. 1—Arrangement of Controls

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T3. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the 1st detector and I.F. tubes.

A 6E5 triode tube functions as the first audio amplifier while the output stage uses a 6F6 output pentode tube. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

Replacement Parts

NOTICE—There is a large letter on the chassis which identifies the set to major part changes. When ordering parts, please be sure to mention the letter number and this large letter. With the exception of the parts otherwise indicated, the following parts are common to Series A1 chassis using either the Telephone Dial or the Phantom Light Dial.

MISCELLANEOUS table listing parts like Tubes, Sockets, and other components with their respective part numbers and descriptions.

TRANSFORMERS AND COILS table listing various transformer and coil models such as 117-234, 117-234, and 117-234.

CONDENSERS table listing different types of capacitors like electrolytic, mica, and paper capacitors.

RESISTORS table listing various resistor values and types such as carbon and wire wound resistors.

PHONO ATTACHMENT PARTS table listing components for the radio's phono section, including tone controls and volume knobs.

DIAL AND DRIVE ASSEMBLY table listing parts for the radio's tuning dial and drive mechanism.

CONDENSERS (Cont.)

TUBULAR (Cont.) table listing tubular capacitor models and their specifications.

ELECTROLYTIC table listing electrolytic capacitor models and their specifications.

MISCELLANEOUS table listing miscellaneous capacitor models and their specifications.

RESISTORS table listing resistor models and their specifications.

PHONO ATTACHMENT PARTS table listing phono attachment parts.

DIAL AND DRIVE ASSEMBLY table listing dial and drive assembly parts.

CONDENSERS table listing capacitor models and their specifications.

RESISTORS table listing resistor models and their specifications.

PHONO ATTACHMENT PARTS table listing phono attachment parts.

DIAL AND DRIVE ASSEMBLY table listing dial and drive assembly parts.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BANDSWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	INITIAL STEPS	PROCEDURE	ADJUSTMENT
RANGE B								
1. F.	2nd I.F. Adj. Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output	
	1st I.F. Adj. Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C22) & (C23)	Turn Rotor to Full Open	Adjust to Maximum Output	
	1830 KC Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C13)	Turn Rotor to Full Open	Adjust to Maximum Output	
	1500 KC Range B	200 mmf.	1500 KC	Antenna Lead	Ant. Range B (C4) Int. Range B (C8)	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Adjust to Maximum Output	
RANGE C								
	600 KC Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C15)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B	
	6350 KC Range C	400 Ohm	6350 KC	Antenna Lead	Oscillator Range C (C12)	Turn Rotor to Full Open	Adjust to Maximum Output	
	6000 KC Range C	400 Ohm	6000 KC	Antenna Lead	Antenna Range C (C3) Int. Range C (C7)	Turn Rotor to Max. Output	Adjust to Maximum Output	
RANGE D								
	2000 KC Range C	400 Ohm	2000 KC	Antenna Lead	2000 KC (C14)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B	
	22,000 KC Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C11)	Turn Rotor to Full Open	Adjust to Maximum Output	
	20,000 KC Range D	400 Ohm	20,000 KC	Antenna Lead	Ant. Range D (C2) Int. Range D (C6)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B	
	7000 KC Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C18)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B	

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

CONDENSERS

Table with columns: Part No., Description, Price. Lists condenser models.

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true—the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the front panel of the chassis base is a round knockout 1/4 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—see Fig. 2.

117-234 Volt Power Transformers

Some models are equipped with a 117-214 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 214 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1 1/2 inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Manual issued for this chassis.

Changes in Later Models

Later models of this series have the following changes incorporated in them.

On the first models, the 2nd I.F. Coil was not expanded. In other words, the extra selectivity coupling winding was not incorporated in the early type coil. Models with the letter "C" or any later issue stamped on the chassis use the new type coil with the selectivity coupling winding. Because of the change in coil connections, the selectivity switch used on the late model is not interchangeable with that on the early model.

When ordering parts, therefore, it is important that the issue letter on the chassis be noted and the correct part number as shown in the parts list be specified.

The R.F. circuit of early models was slightly different from that used in later models. The screen grids of the R.F. and I.F. tubes now supplied by separate voltage sources were formerly connected together and supplied from a single source. On the latter models, resistor R 28 and condenser C 46 were not used.

Fig. 1—Arrangement of Controls

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Prices Subject to Change Without Notice.

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

MODEL 787
Alignment
Notes

GAMBLE-SKOGMO, INC.

Including Cathode-Ray Tuning Indicator
3-Band A. C. Superheterodyne Receiver

TUNING RANGE—
Standard Broadcast Band
535-1720 Kilocycles.

Middle Wave Band
1695-5500 Kilocycles.
Short Wave Band
5.2-18.2 Megacycles.

BROADCAST BAND ALIGNMENT:

- 535 to 1720 Kilocycles
1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3).
(b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
(c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis, directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
(e) Check for tracking and sensitivity at 1000 Kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

- 5.2 to 18.3 Megacycles
1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
(a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
(b) Re-set external oscillator to 5 megacycles and pick up signal by rotating variable condenser and check sensitivity.
(c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage. It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

- 1695 to 5500 Kilocycles
1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
(a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
(b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
(c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.
Dummy 2: (Broadcast)—Consists of a 200 mfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS; (465 K.C.):

Part No. 108-73 Output I.F. Transformer.
Part No. 108-74 Input I.F. Transformer.

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.
- (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

ALIGNMENT PROCEDURE:

The following adjustments to be made after the I.F.'s have been aligned as explained above.

DESCRIPTION:

Model 787 is a seven tube A.C. all wave superheterodyne receiver. It has a tuning range of 535 K.C. to 18.3 megacycles in three bands, and is characterized by its exceptional stability, and by a sensitivity both high and uniform, with high signal to noise ratio on all bands. The I.F. frequency used is 465 K.C., which in conjunction with the pre-selector circuit, gives high image and I.F. attenuation (freedom from whistles and telegraphic interference).

A separate oscillator, effective automatic volume control, broad nose sharp skirt selectivity and new type oval airplane dial, are a few of the outstanding features of this model.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225 and 240 volts (see instructions), and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universal.

TUBE COMPLEMENT:

The tube complement of the model 787 consists of the latest metal tubes. They are as follows:

- 1-Type 6L7 Pentagrid Mixer, First Detector.
- 1-Type 6C5 Oscillator.
- 1-Type 6K7 Remote Cut-off Pentode, I.F. Amplifier (465 K.C.).
- 1-Type 6Q7 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
- 1-Type 6F6 Pentode Output Amplifier.
- 1-Type 5W4 High Vacuum Rectifier.
- 1-Type 6G5 Cathode-Ray Tuning Indicator.
(Note: 6G6 available in all glass only.)

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 110 volts on the primary of the power transformer.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in I.F.C. voltages is usually caused by a shorted electrolytic condenser. Bypass condensers frequently cause oscillation and distorted tone.

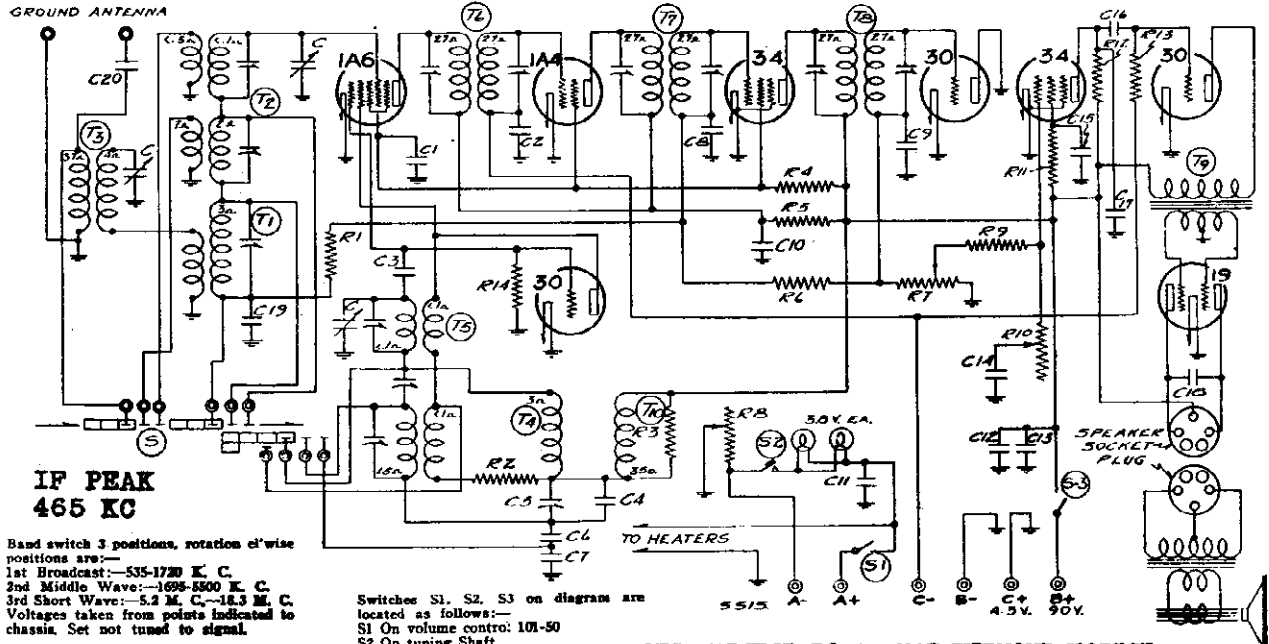

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open

Notes

GAMBLE-SKOGMO, INC.

BAND	DIAL SCALE	FREQUENCY RANGE
Broadcast.....	Outer Scale.....	535 to 1720 K.C. (Kilocycles)
Middle Wave.....	Center Scale.....	1695 to 5500 K.C. (Kilocycles)
Short Wave.....	Inner Scale.....	5.2 to 18.3 M.C. (Megacycles)

BATTERIES REQUIRED:

The following batteries are required:

- 2—45 Volt "B" Batteries.
- 1—4½ Volt "C" Battery.
- 1—3 Volt Dry "A" Battery or 2 Volt Storage Battery.

TUBES:

The tube complement of this chassis is as follows:

- 1—Type 1A6 Pentagrid Mixer, First Detector.
- 1—Type 1A4 Tetrode First I.F. Amplifier (465 K.C.)
- 1—Type 34 Remote Cut-Off Pentode, 2nd I.F. Amplifier (465 K.C.)
- 1—Type 30 Oscillator.
- 1—Type 80 Second Detector and A. V. C.
- 1—Type 34 A.F. Amplifier.
- 1—Type 30 Driver Amplifier.
- 1—Type 19 Class "B" Push-Pull Output Amplifier.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram, are measured with a new set of batteries.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

The approximate current consumption is as follows:

"A"—660 ma., "B"—18 to 24 ma.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the two plate terminals of the type 19 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

- Part No. 108-79 Output I.F. Transformer
- Part No. 108-78 Interstage I.F. Transformer
- Part No. 108-77 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 34 tube, and adjust the output I.F. transformer (No. 108-79) to resonance.

- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 34 to grid cap to 1A4 and adjust interstage I.F. transformer (No. 108-78) to resonance.
- (c) Move oscillator to grid cap of 1A6 and adjust input I.F. transformer (No. 108-77).

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground posts, make following adjustments:
 - (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 1; see bottom view of coil assembly, Fig. 3)
 - (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment).
 - (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
 - (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
 - (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.2 to 18.3 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the antenna and ground posts, make the following adjustments:
 - (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 3) and short wave antenna (adjustment number 6) to resonance.
 - (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
 - (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle signal can be tuned in not only at 18.3 on the dial but also at approximately 17.4 megacycles.

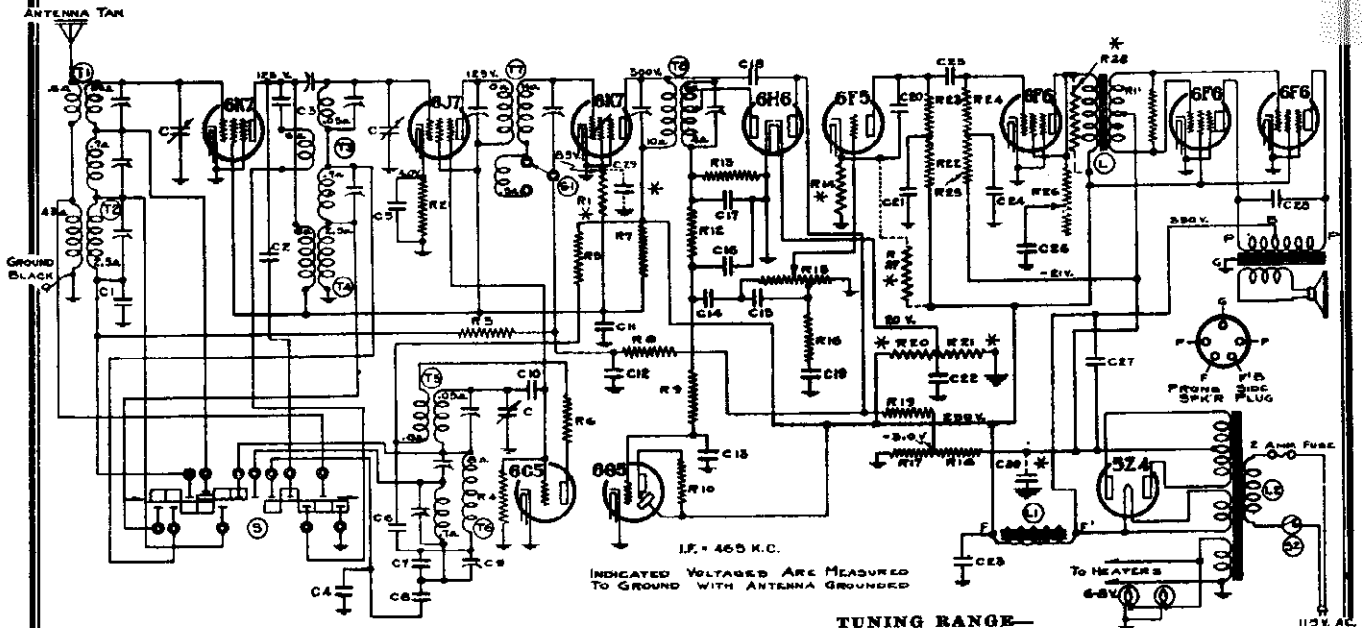

MIDDLE WAVE BAND ALIGNMENT:

1695 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the antenna and ground posts make the following adjustments:
 - (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (adjustment number 2) and middle wave antenna (adjustment number 5) to resonance.
 - (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
 - (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

S1	101-40 Fidelity Switch on Tone Control
S2	101-47 On-Off Switch on Volume Control

NOTE: Resistors and Condensers which are prefixed with an asterisk (*) on the circuit diagram and parts list were added or the values changed during production to meet certain conditions.

Resistors R1, R27, R28, and Condensers C29, C30 were added to correct certain variances of tube characteristics. Resistors R14, R20, R21 the values were changed. In some chassis the values of these resistors are as follows:
 R14—2500 Ohm—1/2 Watt
 R20—200M Ohm—1/2 Watt
 R21—20M Ohm—1/2 Watt
 Present values of these resistors are:
 R14—500 Ohm—1/2 Watt
 R20—100M Ohm—1/2 Watt
 R21—10M Ohm—1/2 Watt

MODEL 1170

GAMBLE-SKOGMO, INC.

Alignment, Notes

(c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

ALIGNMENT PROCEDURE

The following adjustments to be made after the I.F.'s have been aligned as explained above.

BROADCAST BAND ALIGNMENT:

1. With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:

- (a) Adjust broadcast series pad (adjustment number 3) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 3.
- (b) Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 1.
- (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

NOTE: IT IS EXTREMELY NECESSARY IN MAKING ALL OF THESE ADJUSTMENTS THAT THE FUNDAMENTAL OSCILLATOR SIGNAL BE TUNED IN AND NOT THE IMAGE FREQUENCY WHICH WILL FALL BELOW THE FUNDAMENTAL.

SHORT WAVE BAND ALIGNMENT:

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

- (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.
- (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

MIDDLE WAVE BAND ALIGNMENT:

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

- (a) Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.
- (b) Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. middle wave adjustments.

ampere fuse. If replacement fuse blows out, check tubes, particularly 5Z4 rectifier) circuit, repair or replace defective tubes or parts.

NEVER ATTEMPT TO REPLACE FUSE WITHOUT FIRST DISCONNECTING POWER.
NEVER REPLACE WITH FUSE OTHER THAN 2 AMPERE RATING.

ALIGNING INSTRUCTIONS

Dummy Antennas

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

- Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.
- Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.
- Dummy 3: (Intermediate and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output.

A low range output meter or the low scale of a multi-range meter should be used.

CAUTION:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the four bolts by which it is fastened.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer
These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view Fig. 1).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.
- (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.

DESCRIPTION

The tube complement of this chassis is as follows:

- 1—Type 6K7 Remote cut-off pentode R.F. amplifier
- 1—Type 6J7 Pentode first detector
- 1—Type 6C5 Oscillator
- 1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
- 1—Type 6H6 Duplex diode second detector and A.V.C.
- 1—Type 6F5 First audio amplifier
- 1—Type 5F6 Triode driver stage
- 2—Type 6P6 Class AB Output pentodes in push-pull
- 1—Type 5Z4 High vacuum rectifier
- 1—Type 6G5 Cathode Ray Tuning Indicator.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts. (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES

NOTE: DeLuxe Model 1172 differs only from the Model 1170 in that dual speakers and a de luxe console cabinet are used. Both chassis are identical and the circuit diagram, the alignment procedure and the parts list contained in this manual apply to both models.

Attention is called to the circuit diagram contained in this manual. Several minor changes were made during production of these models to correct certain conditions. These changes are shown on the circuit diagram in dotted lines and explained in detail. Some of the chassis were equipped with 5Z3 rectifier tubes in place of the 5Z4 and do not have a fuse assembly in the power line.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

This chassis is protected against damage from faulty tubes or abnormal line conditions by a fuse in the primary circuit.

If when set is turned on pilot lights do not light, look for a blown fuse.

This fuse is made accessible for replacement by removing fuse cover located on back flange of chassis, replace only with a 2

OUTPUT TRANSFORMER

GAMBLE-SKOGMO, INC.

MODEL 5953A
Alignment, Parts

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube. Leave the grid cap disconnected and connect a 1 meg ohm resistor from the modulator grid to the chassis base. Connect the ground side of the oscillator to the receiver ground lead.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the other intermediate transformers in the same manner.

NOTE: Two types of intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

5. Adjust the IF regeneration trimmer located underneath the chassis for maximum 465 kilocycle signal sensitivity. If adjustment of this trimmer causes the receiver to oscillate always adjust to a point where oscillation just stops, and then back off 1/8 turn.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser and padding and trimmer condensers to follow the procedure given carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The two coils located on the underside of the chassis which have trimmer condensers mounted on them will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the set antenna lead and the ground to the set ground.
2. Place the band selector switch for operation on the 15.8 to 5.6 megacycle band, tune the receiver to EXACTLY 14 MEGACYCLES on the dial, and set the test oscillator frequency to EXACTLY 14 MEGACYCLES. THEN BRING IN THE 14 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER. Looking at the front of the receiver the oscillator section is the rear section of the gang condenser. When adjusting this trimmer two peaks, the fundamental and the image peak, will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 14 MEGACYCLES. First back off the trimmer to minimum capacity, next screw down the trimmer (add capacity) until the first peak, which is the fundamental and the one you are to use, is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust the trimmer to bring in the 14 megacycle signal to maximum output. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 14 megacycles, increase the output of the test oscillator and then tune the receiver dial to approximately 13 megacycles. Vary the receiver dial slightly to the right and left of 13 megacycles and if the fundamental peak was used in aligning at 14 megacycles the test oscillator signal will be heard at approximately 13 megacycles on the receiver dial. If it is not possible to receive the signal then the fundamental peak was not used and the 14 megacycle adjustment of the trimmer on top of the oscillator section of the gang condenser must be gone over and properly adjusted.
3. Set the band selector switch for operation on the broadcast band (1720-530 K.C.) adjust the test oscillator frequency to EXACTLY 1400 KILOCYCLES and the receiver dial to EXACTLY 1400 KILOCYCLES. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 1720-530 KILOCYCLE TRIMMER (see circuit diagram) mounted on one of the coils located underneath the chassis. Next adjust the trimmer located on the front section of the gang condenser for maximum 1400 kilocycle signal sensitivity.
4. Leave the band selector switch for operation on the broadcast band (1720-530 K.C.), tune the receiver dial and set the test oscillator frequency to approximately 600 kilocycles. While rocking the gang condenser slightly to the right and left adjust the 1720-530 kilocycle trimmer which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity.
5. Recheck the 1400 kilocycle signal adjustment.
6. Place the band selector switch for operation on the short wave 15.8 to 5.6 megacycle band, set the test oscillator frequency to EXACTLY 14 MEGACYCLES and tune the receiver to EXACTLY 14 MEGACYCLES. While rocking the gang condenser slightly to the right and left adjust the 5.6 to 15.8 megacycle trimmer (see circuit diagram) mounted on one of the coils underneath the chassis.

This completes the alignment and it is recommended that all the adjustments be gone over again, as generally it will be found that improved results can be obtained if this is done. Assuming that all tubes and component parts of the set are okay, then extreme inaccuracies in the dial calibration, low sensitivity, and poor selectivity are indications that the alignment procedure has not been followed.

MODEL 850B

GAMBLE-SKOGMO, INC.

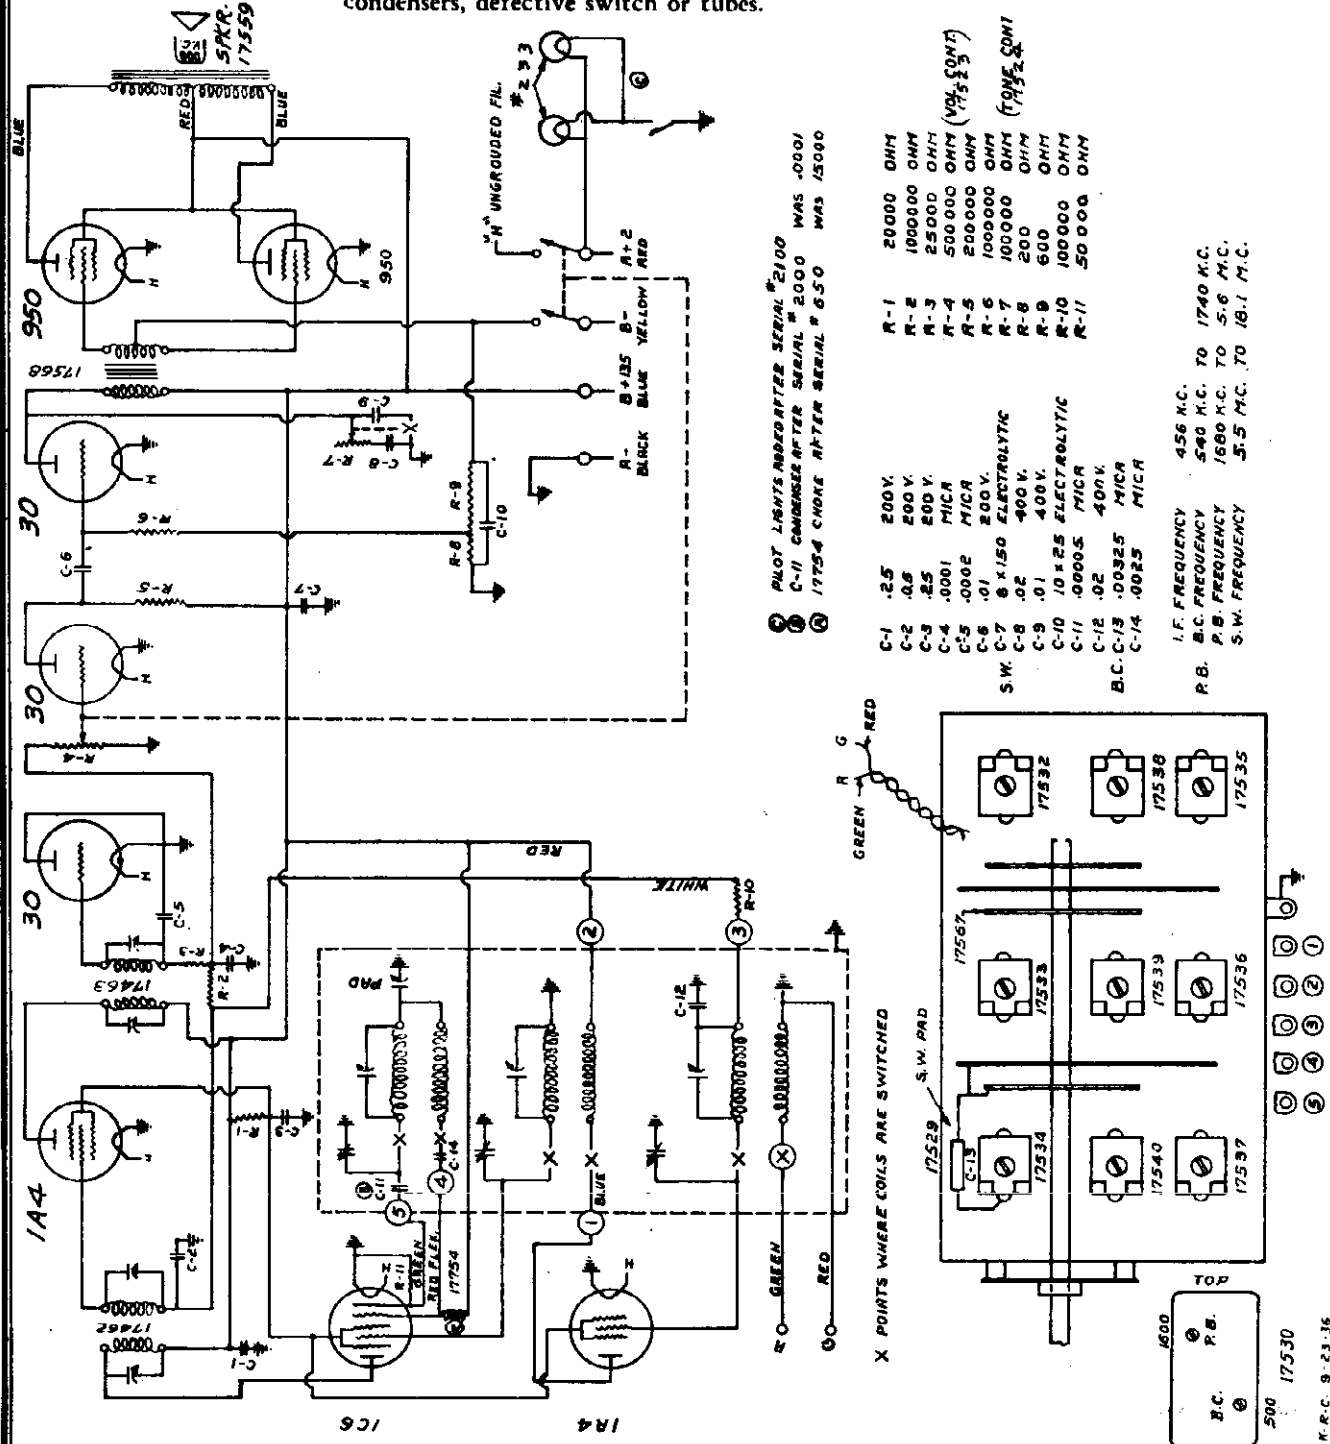

Schematic, Trimmers Alignment

ALIGNMENT. Refer to "Alignment" in 11-B notes. Connect signal generator to grid cap of 1-C-6 tube for IF alignment.

BELT AND DIAL REPLACEMENT. Belt may be replaced without removing any parts on this model. Also see notes on 11-B dial and belt.

TUBE FUNCTIONS. 1-A-4 R. F. Stage on all wave bands, 1-C-6 first detector-oscillator, 1-A-4 intermediate amplifier, "30" as diode detector, "30" as first audio, "30" as second audio, two type 950 Pentodes operating in push-pull class A prime as power tubes.

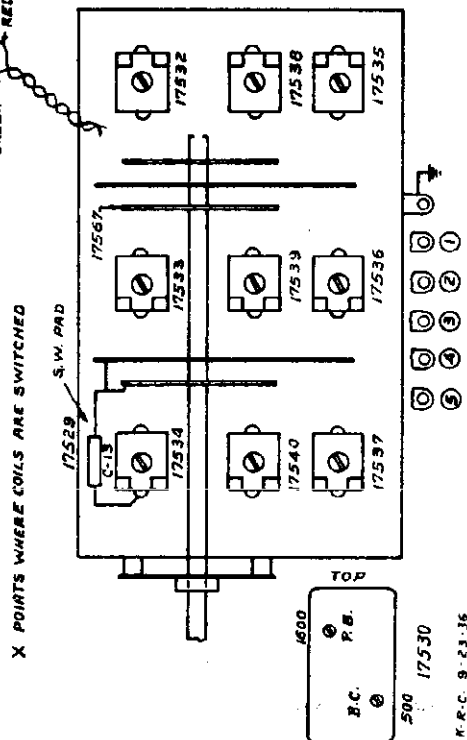

Excessive Battery Drain This should always be checked with a meter, since some people use a set more than they realize or may leave it "on" over night. The "A" drain should measure not over .68 amp. and the "B" 20 to 22 Milliamperes on low volume—increasing some when tuned in on high volume. Causes of excessive drain can usually be traced to shorted or leaky condensers, defective switch or tubes.

GAROD RADIO CORP.

MODEL Challenger I
Schematic, Socket
Alignment, Voltage

2/24/37

This receiver operates on either direct current or alternating current of any frequency on voltage between 105 and 130. If voltages in excess of this value are to be applied to the receiver, a special Ballast Tube must be used. When operating from direct current, if after the receiver has been turned on for about three quarters of a minute, no reception is obtained, the plug must be reversed in the socket. On alternating current, there is generally no difference, though sometimes quieter operation results.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. The "hot" lead from the signal generator is connected to the grid cap on the 1st detector (6A7) tube, the clip having first been removed from the tube cap. The ground lead is connected to the receiver chassis. The oscillator section (front) of the gang tuning condenser is short-circuited and the volume control turned on full. The i.f. trimmers are then adjusted for maximum gain in the receiver. These trimmers are located on top of the i.f. transformer shield can and on the chassis to the left of the 6D6 tube. The one towards the right is the 1st i.f. transformer and the left one is the 2nd i.f. transformer. The oscillator section of the variable condenser is the one nearest the front of the chassis. The antenna trimmer is then adjusted for maximum output.

1500 KILOCYCLE ADJUSTMENT - The short-circuit is removed from the oscillator condenser and the grid clip replaced in its normal position on the cap of the 6A7 tube. The "hot" lead from the signal generator is connected to the antenna lead of the receiver and the ground lead to the ground of the receiver. With the volume control set at maximum and a minimum input signal from the signal generator, the band switch is turned to the left and the receiver dial set at 1500 K.C. The oscillator trimmer is adjusted so as to bring the signal in at this setting.

456 K.C. WAVE TRAP ADJUSTMENT: The signal generator is again set to 456 kc. The output of the signal generator is increased so as to obtain a good reading (about half scale) on the output meter connected to the receiver. The wave trap is then adjusted for a **MINIMUM** reading by rotating the trimmer on top of the antenna coil. This is located directly behind the dial scale.

VOLTAGE TABLE

TUBE	FUNCTION	H.T.'R	PLATE	SC. GR.	GATE	GRG. PL.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A8). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on tops of the i.f. transformer shield cans.

MODEL 380

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc signal is tuned in exactly at the 18 mc calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the sides of the shield cans and are opposite the lower openings. This is the only adjustment on Band #1.

1500 K.C. ADJUSTMENT - With the band selector switch in position for operation on band no. 3. and the receiver and signal generator both set at 1500 K.C. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is opposite the upper opening. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans. The signal generator is set at 600 K.C. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 1500 K.C. adjustment should then be rechecked. The 600 K.C. Padder is located as indicated in the sketch.

3 MC. ADJUSTMENT - The band selector switch is set in position for operation on the No. 2. band. The receiver and signal generator are both set at 3 M.C. and the procedure outlined above is repeated. The oscillator trimmer is found on the Police Band Coil located under the chassis and is towards the rear. The other trimmers for this band are located in similar positions on the corresponding coils. The signal generator is set at 1.7 M.C. and the signal tuned in on the dial. The padder condenser for the police band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 3 M.C. adjustment should then be rechecked. The 1.7 MC. padder is located as indicated.

MODEL 381

Model 381 is the same as Model 380 except that the Long Wave band is substituted for the Police Band. Alignment procedure is identical for the Short Wave and Broadcast Bands. The Long Wave Band is aligned as follows:

300 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 3. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located under the chassis and is mounted on the rear coil. The signal generator is set at 150 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked. The 150 kc. padder is located as indicated.

All voltages except filament, are measured from socket terminals to chassis and with a 1000 Ohms per volt voltmeter. The set must be in operation and the sensitivity control in its maximum clockwise position. Wave Band switch in broadcast position. Filament voltages are taken from filament prong to filament prong at tube socket and measured with a low impedance AC voltmeter.

MODEL 620
Schematic
Alignment

GAROD RADIO CORP.

from the signal generator, the band switch is turned to the left and the receiver dial set at 14 mc. The oscillator trimmer is adjusted so as to bring the signal in at this setting. The oscillator coil is underneath the chassis and is located directly under the variable gang condenser. The short wave trimmer is over the short wave winding (Heavy spaced wire). After the oscillator is set, the antenna trimmer is adjusted for maximum output as indicated by the output meter. (Again the S. W. antenna trimmer is located over the heavy spaced winding on the antenna coil, and is accessible from the top of the chassis.) There are no other adjustments on this band.

1500 KC. KILOCYCLE ADJUSTMENT - Turn the Wave Band Switch to the right. Set the signal generator to 1500 kc. and turn the dial pointer to correspond to this frequency. Adjust the oscillator trimmer for this band so that the signal is received exactly at this setting. (This trimmer is located over the close-wound fine winding on the oscillator coil.) Adjust the Broadcast antenna trimmer for maximum output as described previously. (This trimmer is over the small 5 section winding and is accessible from the top.)

500 KC. PADDER ADJUSTMENT - With all connections as above, the signal generator is set at 600 KC and the front sub-panel of the receiver, directly under the dial. This padder should be adjusted for maximum response of the receiver, while the tuning condenser is rocked slightly back and forth. The 1500 KC adjustment should then be rechecked.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. The "hot" lead from the signal generator is connected to the grid cap on the 1st detector (6A7) tube, the clip having first been removed from the tube cap. The ground lead is connected to the receiver chassis. The oscillator section (front) of the gang tuning condenser is short-circuited and the volume control turned on full. The i.f. trimmers are then adjusted for maximum gain in the receiver. These trimmers are located on top of the i.f. transformer shield cans, which are situated in the rear of the chassis. The one towards the right is the 1st i.f. transformer and the left one is the 2nd i.f. transformer.

14 MEGACYCLE ADJUSTMENT - The short-circuit is removed from the oscillator condenser and the grid clip replaced in its normal position on the cap of the 6A7 tube. The "hot" lead from the signal generator is connected to the antenna lead of the receiver and the ground lead to the ground of the receiver. With the volume control set at maximum and a minimum input signal

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have first been thoroughly investigated. An accurately calibrated signal generator which will cover the various wavebands, and an output meter for indicating the effects of adjustments, are required.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A8). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on tops of the i.f. transformer shield cans.

MODEL 930

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc signal is tuned in exactly at the 18 mc calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and first detector trimmers are then adjusted in the order named for maximum output. These trimmers are located on the sides of the shield cans and are opposite the lower openings. This is the only adjustment on band #1.

1500 K.C. ADJUSTMENT - With the band selector switch in position for operation on band no. 3. and the receiver and signal generator both set at 1500 K.C. the procedure outlined above is repeated. The oscillator trimmer is found on the rear coil can, and is opposite the lower opening. The antenna preselector and interstage coil trimmers are located in the same positions on the corresponding shield cans.

The signal generator is set at 600 K.C. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 1500 K.C. adjustment should then be rechecked. The 600 K.C. Padder is located as indicated in the sketch.

3 MC ADJUSTMENT - The band selector switch is set in position for operation on the no. 2. band. The receiver and signal generator are both set at 3 M.C. and the procedure outlined above is repeated. The oscillator trimmer is found on the police band coil located under the chassis and is towards the rear. The other trimmers for this band are located in similar positions on the corresponding coils.

The signal generator is set at 1.7 M.C. and the signal tuned in on the dial. The padder condenser for the police band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 3 M.C. adjustment should then be rechecked. The 1.7 M.C. padder is located as indicated.

MODEL 931

Model 931 is the same as Model 930 except that the Long Wave band is substituted for the Police Band. Alignment procedure is identical for the Short Wave and Broadcast Bands. The Long Wave Band is aligned as follows:

300 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 3. The receiver and generator are both tuned to 340 kc. and the procedure outlined above is repeated. The oscillator trimmer is located under the chassis and is mounted on the rear coil. The signal generator is set at 150 kc. and the signal is tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked. The 150 kc. padder is located as indicated.

All voltages except filament, are measured from socket terminals to chassis and with a 1000 Ohms per volt voltmeter. The set must be in operation and the sensitivity control in its maximum clockwise position. Wave band switch in the broadcast position.

Filament voltages are taken from filament prong to filament prong at tube socket and measured with a high impedance AC voltmeter. (Rectifier Type)

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6AB). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the tops of the I.F. Transformers.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc. signal is tuned in exactly at the 18 mc. calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and interstage trimmers are then adjusted in the order named for maximum output. These trimmers are located as indicated in the bottom view of the chassis.

6 MEGACYCLE ADJUSTMENT - The signal generator is set at 6 megacycle and the signal tuned in on the dial. The short wave padding condenser is adjusted for maximum output, while the gang condenser is rocked slightly to the right and left. The 18 megacycle adjustment should then be rechecked.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 2. and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated.

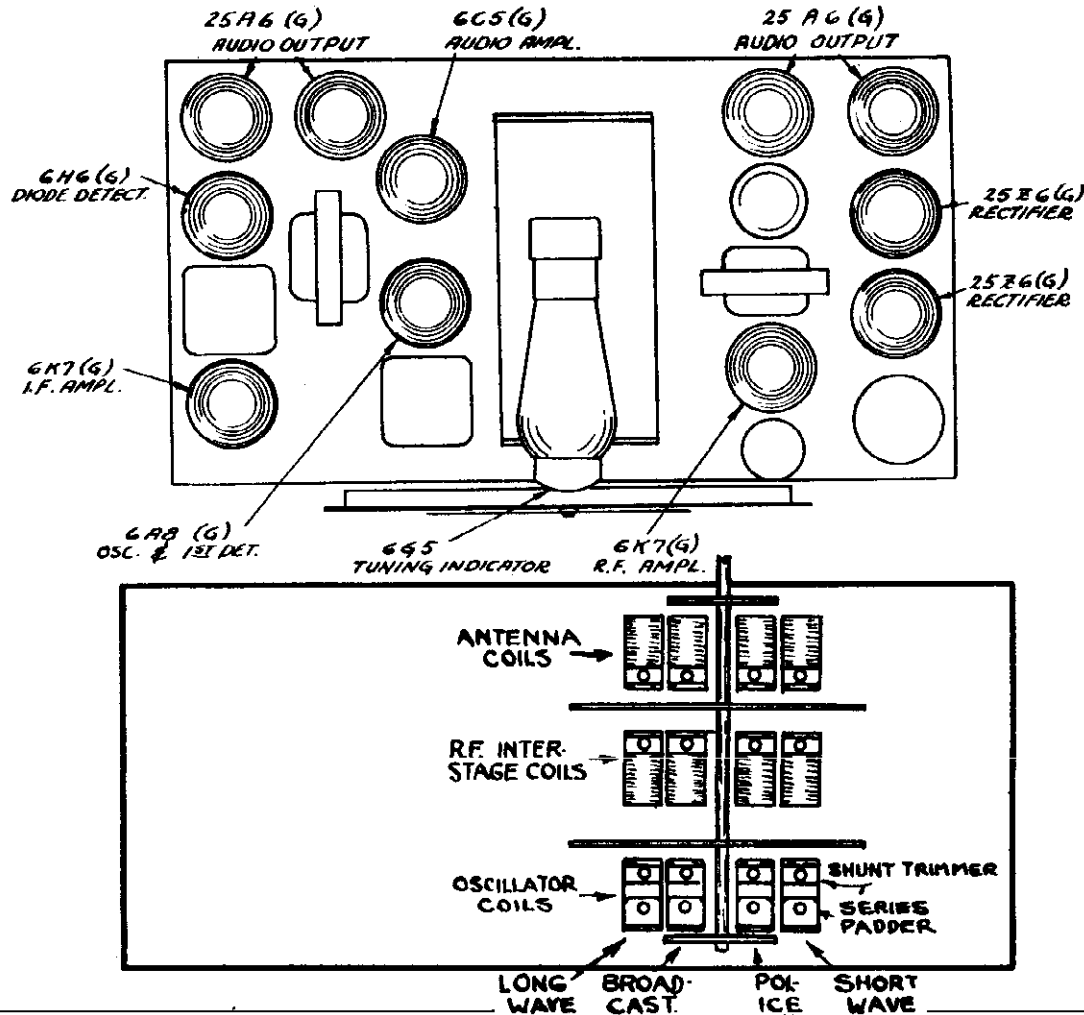

The signal generator is set at 1.8 mc. and the signal tuned in on the dial. The police band padder condenser is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked.

1500 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 3. band. The receiver and signal generator are both set at 1500 kc. and the procedure outlined above is repeated.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The broadcast padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1500 kc. adjustment should then be rechecked.

300 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 300 kc. and the procedure outlined above is repeated.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The long wave padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked.

SERVICE NOTES FOR THE MODEL 5240
24 TUBE 5 BAND A.C. SUPERHETERODYNE RECEIVER
ALIGNMENT PROCEDURE

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6L7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the tops of the I.F. transformers.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 2 (short wave). The oscillator trimmer condenser is adjusted so that the 18 mc. signal is tuned in exactly at the 18 mc. calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and inter-stage trimmers are then adjusted in the order named for maximum output. These trimmers are located as indicated in the bottom view of the chassis.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 3. (Police) and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated.

6 MEGACYCLE ADJUSTMENT - The signal generator is set at 6 megacycles and the signal tuned in on the dial. The Short Wave padding condenser is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left.

The signal generator is set at 1.8 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked.

1500 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 4 band (Broadcast). The receiver and signal generator are both set at 1500 kc. and the procedure outlined above is repeated.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1500 kc. adjustment should then be rechecked.

300 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 5. The receiver and generator are both tuned to 300 kc. and the procedure outlined above is repeated.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The Long Wave padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked.

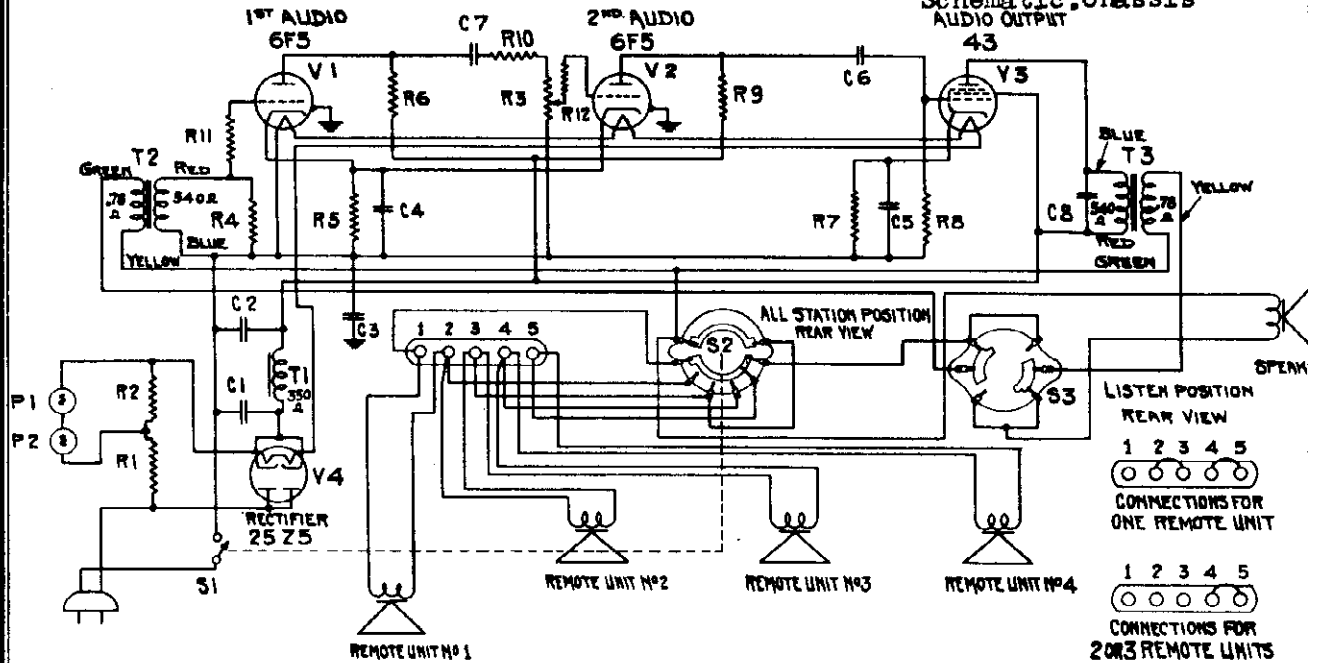

BEAT OSCILLATOR ADJUSTMENT - The signal generator, set at 456 K.C. is connected to the mixer tube (6L7) as described for the I.F. adjustment. The modulation switch is set to the "OFF" position and only a hiss or slight hum should be heard. Turn the Beat Oscillator "ON". If this is in exact adjustment (zero beat) no signal should be heard. If it has drifted however, a whistle will be heard the pitch of which can be varied by rotating the screw protruding from the side of square can on the left side of the chassis. As this is turned the pitch will change from high to low, then pass through a zero point, and then it will rise again in frequency. The "Zero Beat" position, where no signal is heard is the correct setting.

AUTOMATIC FREQUENCY CONTROL - Should it be found that after a station is tuned in accurately (in the selective position) as indicated by the cathode ray tube, that when the A.F.C. switch is turned "ON", the signal is detuned or a change observed in the tone of the receiver, it will be necessary to readjust the "Discriminator" transformer which controls this action. A low range (0-5 or 0-10V.) high resistance volt meter or preferably a microammeter is inserted in series with the diode load resistor at the grounded end, which will indicate a maximum when a signal is tuned to exact resonance. This 500,000 Ohms load resistor is located directly under the discriminator transformer. A 0-10 milliammeter is inserted in the cathode circuit of the A.F.C. control tube. An R.F. signal (any frequency in the Broadcast Band) is fed into the antenna and the receiver is tuned as accurately as possible to resonance (with the switch turned OFF). Now throw the secondary trimmer of the discriminator off resonance. Tune the primary for maximum output as indicated by the diode load meter. Turn the AFC switch "ON". Now tune the secondary trimmer, identified by a red paint mark, so that when the A.F.C. switch is turned from the ON to the OFF position and vice-versa, no change takes place in the cathode current of the A.F.C. control tube, as indicated by the milliammeter. Be sure that the receiver has been accurately tuned first without the A.F.C., or improper adjustment may result, whereby the frequency is automatically detuned instead of tuned. When this condition of no change in cathode current is obtained, it is indicated that no control voltage is being generated at exact resonance, which is the desired condition. If now the receiver is slightly detuned either above or below resonance, the cathode current will either increase or decrease above its normal value with the A.F.C. OFF, or no signal fed into the antenna. The voltage thus generated as indicated by this change in current serves to shift the frequency of the oscillator in the proper direction so as to automatically retune the oscillator to the exact frequency required to bring in the desired station with maximum clarity and a minimum of noise.

NOTE - IN ALLIGNING THE BROADCAST BAND (1500 KC AND 600 KC) THE A.F.C. MUST BE OFF

All voltages except filament measured with 1,000 Ohms per volt meter from socket to chassis with band switch in broadcast position, and fidelity switch in selective position. Filament voltages are taken across filament prongs at tube socket and measured with a low impedance AC Voltmeter.

- Voice Coil Impedance . . 5.0 ohms at 400 cycles

GENERAL INFORMATION

The Handy-Phone is an efficient loudspeaker phone system for use in offices, homes, hospitals or other places where voice communication between a central station and one or more remote stations is desirable. The system consists of one Model FM-41 Master Station and from one to four Model FS-5 remote "speaker-phone" stations.

The Master Station Model FM-41, employs four General Electric tubes in a three stage audio amplifier circuit with power supply. Volume is controlled by a variable potentiometer R-3 in the grid circuit of the 2nd audio amplifier. The "speaker-phone" used in this unit is of the permanent magnet type and is connected either as a microphone to the input circuit of the amplifier or as a loudspeaker to the output circuit of the amplifier by means of the talk-listen switch (S-3).

The heaters of all tubes and the dial lights with their shunt ballast resistor (R-2) are all in series and are furnished current from the power line through a dropping resistor (R-1). The two 6F5 tubes use the common self-biasing resistor R-5 for obtaining grid bias. The 43 output tube is self-biased by the voltage drop in R-7.

Note that the chassis is not the "B-" lead of the power supply. This "B-" lead is by-passed to the chassis through the capacitor C-3.

The Remote Station FS-5 uses a similar "speaker-phone" of the permanent magnet type but does not incorporate an amplifier or power supply; all operating power being supplied from the Master Station unit. The Remote Station speaker is also connected either to the input or output circuits of the amplifier in the Master Unit by means of the talk-listen switch (S-3).

As an example of the operation of the system: When the talk-listen switch (S-3) is in the normal "listen" position, the Remote Station functions as a microphone and is connected to the input of the amplifier while the Master Station speaker is connected across the output of the amplifier. When S-3 is placed in the "talk" position, the Master Station speaker then functions as a microphone and is connected to the input of the amplifier, while the Remote Station is connected to the output of the amplifier and functions as a speaker. The selector switch (S-2) connects either any one individual Remote Station or all Remote Stations to the Master unit. When the selector switch (S-2) is turned to the all position, the Remote Station units are connected in a series-parallel combination across the output of the amplifier.

DC Operation

When operating from a D.C. source, it is necessary to insert the plug with proper polarity. If the unit fails to function, after allowing time for the tubes to reach their operating temperature, reverse the power plug in the receptacle.

When the system is used on a D.C. supply, the 25Z5 rectifier tube and the filter remain in the circuit and serve two purposes. If the power cord should be plugged in with incorrect polarity, the 25Z5 tube protects the filter condensers from damage. On correct D.C. polarity the 25Z5 tube passes the D.C. and the filter circuit aids in smoothing the supply voltage, thus minimizing line noise.

AC Operation

When the system is used on alternating current, all D.C. potentials are supplied by a 25Z5 rectifier tube and its associated filter circuit. The tube is connected as a half-wave rectifier.

If any hum is noticed when the system is used on A.C., reverse the power plug in the receptacle. When the system has not been used for some time, a slight hum may be audible when the system is first turned on. This hum may not immediately clear up upon reversal of the power plug. However, it will probably be eliminated after approximately five minutes operation by which time the anode plates of the electrolytic capacitors will have re-formed.

Operating Distance

The following table gives the size of the twisted wire and additional equipment necessary to wire a remote station to the master station for various distances:

Distance of Remote from Master Station	Wire Size	Additional Equipment
1—500 Feet	No. 19—No. 22 B & S Gauge	None
500—2000 Feet	No. 16—No. 19 B & S Gauge	None
2000 Feet and Over	No. 19 B & S Telephone Wire	*Line Transformers

* Standard line transformers may be used. The transformers should be designed to operate from a five-ohm source into a line of 200, 500 or 600 ohms impedance. A similar transformer should be used on the remote station end to match the line impedance to the five-ohm load. These transformers may be procured from any radio supply house.

GENERAL ELECTRIC CO

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. transformer, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coils. The special-cut rotor of the front condenser section permits dispensing with the usual padding capacitor. The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, both of which have tuned primaries and secondaries. Volume is controlled by the 400-ohm variable resistor, R-1, which varies the bias applied to the control grids of the 6A8 and 6K7 tubes. The output of the I.F. amplifier is applied to the grid of the 6C5 detector which is properly biased for this service by the .1 megohm cathode resistor, R-6. The output of the 6C5 detector is resistance coupled to the grid of the 6F8 power amplifier pentode. The plate circuit of the 6F8 is suitably matched to the loud-speaker by means of a step-down output transformer. The tone control circuit consists of a .002 mid. capacitor, connected in series with a two-point grounding switch, S-3, in the grid circuit of the 6F8 power pentode. When it is desired to reduce the high frequency output of the receiver, the switch, S-3, is turned to its counterclockwise grounding position. Plate and grid voltages for all tubes are supplied by the power supply system employing a 5W4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

ALIGNMENT PROCEDURE

Before making any adjustments to the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by applying a signal from the test oscillator to the receiver and inserting a "tuning wand" into the antenna coil. The "tuning wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the brass cylinder end into the antenna coil, the inductance is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in the coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand at the 1000-ke. point or the 4.0-mc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjusted Required
Brass cylinder	Increase	Increase
Iron filings	Increase	None
Brass cylinder	Decrease	Decrease capacity
Iron filings	Decrease	Increase capacity

ALIGNMENT FREQUENCIES

I.F. Broadcast Short-wave
465 Kc. 1500 Kc. 4000 Kc.
In order to align these receivers properly it is necessary to have available:
1. A modulated test oscillator capable of producing the above alignment frequencies.
2. An output indicator, such as a high-resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
The location of all alignment trimmer capacitors are illustrated in Fig. 3.

(1) I.F. Alignment

Set the frequency band switch of the receiver to the broadcast position and turn the volume control to maximum (extreme clockwise position). Tune the receiver to a point where no signal comes in and short-circuit the antenna and ground leads.
Connect the test oscillator output between the chassis and the control grid of the 6A8 tube. Connect the output meter across the control coil of the speaker. Set the test oscillator to 465 kc. and adjust the output until a small deflection is observed in the output meter.
The four I.F. trimmers, see Fig. 3, are adjusted in the following sequence:
1. Secondary trimmer on second I.F. transformer.
2. Primary trimmer on second I.F. transformer.
3. Secondary trimmer on first I.F. transformer.
4. Primary trimmer on first I.F. transformer.

Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output at the various stages are brought in line. After these adjustments have been made, the same procedure should be repeated as a final check. The I.F. alignment will then be complete.

(2) I.F. Wave Trap

No adjustable trimmer is provided for the I.F. trap adjustment in this receiver. The capacitor MC-19, in conjunction with the inductance, L-1, automatically provides rejection of incoming I.F. signals.

(3) R.F. Alignment

The R.F. and oscillator trimmers are aligned at 1500 kc. First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Remove the short-circuit from the antenna and ground terminals and connect the test oscillator to same through a dummy antenna consisting of a 400-ohm resistor in series with a 200-mmf. capacitor. Connect the output indicator across the speaker cone coil.

(4) Broadcast Band—(540-1800 Kc.)

With the band switch in the clockwise position, set the tuning indicator to 1500 kc. Set the test oscillator at 1600 kc. and adjust the broadcast band oscillator trimmer, C-6, for maximum output. Next, set the R.F. trimmer, C-6, for maximum output, taking care that the output from the test oscillator is not high enough to overdrive any part of the set. No padding adjustment is required.
To complete the broadcast band line-up, repeat the R.F. trimmer adjustment after aligning the short-wave band.

(5) Short-wave Band (1800-4000 Kc.)

Turn the band switch to its counterclockwise position. Set the test oscillator at 4000 kc. and tune the receiver to resonate at this frequency. No trimmer is provided for short-wave oscillator alignment. To perform the R.F. short-wave adjustment, rock the tuning condenser back and forth through resonance while adjusting the short-wave R.F. trimmer, C-3, for maximum output indication on the tuning meter. It may now be necessary to readjust the broadcast band R.F. trimmer as indicated above.
Alignment of the receiver is now complete.

Alignment and Calibration

I. F. Adjustment

Set the signal generator for a signal of 175 KC.
 Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.
 Connect the ground lead of the receiver to the ground post of the signal generator.
 Turn the volume control to the maximum position.
 Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.
 Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 6.

1730 KC Adjustment

Set the signal generator for 1730 KC.
 Turn the rotor of the tuning condenser to the full open position.
 Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

Keep the volume control at the maximum position.
 Adjust the trimmer of the oscillator section of the two gang condenser until maximum output is obtained. The location of this trimmer is shown in Fig. 6.

1500 KC Adjustment

Set the signal generator for 1500 KC.
 Turn the rotor of the tuning condenser carefully until maximum output is obtained.
 The dial indicator should be near the 1500 KC mark on the dial scale. If it is a considerable distance from this mark, the position of the indicator on the drive cord must be changed. This procedure, however, should not be followed unless it is absolutely necessary as there is danger of breaking the clamps (See Fig. 8) which hold the indicator in place, and of fraying the drive cord. If the indicator must be moved, loosen the clamps at the back which hold it in place, and then retighten as explained in the article "Replacing Drive Cord."

Adjust the antenna trimmer for maximum output.
 Do not change the setting of the oscillator trimmer.

Grid Lead of 32 1st A. F. Tube

Keep the grid lead of the 32 1st A.F. tube in its normal position as shown in the tube arrangement, Fig. 7. If this lead is swung around so that it is close to the 1F4 output tube, an audio feedback may result which will manifest itself as a squeal.

Replacing Drive Cord

Remove the chassis from the cabinet.
 Remove the old drive cord, pulleys, washer and indicator.

Turn the drive drum until the slot in the rim is in the position shown in Fig. 8.

Insert one end of the drive cord in the slot and wind the cord around the drum in a clockwise direction for about two-thirds of a turn, or until it reaches the top of the drum.

Now, before putting the right pulley (from front) in place, bring the cord around the pulley from back to front so that the cord is adjacent to the celluloid dial scale; then place the pulley in position.

Extend the cord over to the left and bring it around the other pulley from front to back before placing this pulley. Put the small brass washer on the upper shaft of the pulley and place the pulley in position as shown in Fig. 8.

Bring the cord over to the drive drum and wind it around the drum in a clockwise direction, keeping it behind the cord already on the drum.

Push the pulley tension spring in toward the drive drum so as to provide slack in the cord while the free end is being inserted into the slot in the rim.

Now mesh the condenser plates completely. Replace the celluloid indicator on the dial strip and attach it to the drive cord as shown in Fig. 8. The line on the indicator should cover the 530 KC mark on the dial scale.

CAUTION—When attaching the indicator to the drive cord, do not pinch the center clamp too tightly on the cord or the cord will be cut. After the clamp is pinched slightly a small amount of shellac on it will hold the cord securely.

signal is obtained with the iron-filled end of the wand as the 1500-kc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated. In the event that the brass cylinder read causes an increase in output at the 680-kc. point when inserted in the antenna coil, it is necessary to increase the oscillator padder capacity, meanwhile rocking the tuning dial. An increase in output, resulting from inserting the iron-filled end, indicates a decrease in oscillator padder capacity.

ALIGNMENT FREQUENCIES

I.F. Broadcast Short-wave
 465 kc. 1500 kc. None

In order to properly align this receiver, it will be necessary to have the following service tools

1. Test Oscillator capable of producing the above alignment frequencies.
2. Non-metallic alignment screwdriver.
3. Output meter.

Trimmer locations as well as socket voltages are illustrated in Fig. 3.

I.F. Alignment

The I.F. amplifier should be tuned to 465 kc. set the test oscillator dial at this frequency. Turn the volume control to maximum and short-circuit the antenna and ground leads. Connect the test oscillator output between the 6A8 converter tube grid (with the grid cap on) and the chassis. Connect the output meter across the one end of the speaker and adjust the oscillator output until a small deflection is observed in the output meter.

The four I.F. trimmers are adjusted in the following sequence:

1. Secondary trimmer on second I.F. transformer.
2. Primary trimmer on second I.F. transformer.
3. Secondary trimmer on first I.F. transformer.
4. Primary trimmer on first I.F. transformer.

Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output as the various stages are brought in line. After these adjustments have been made, the same procedure should be repeated as a final check. The I.F. alignment will then be complete.

R.F. Alignment

The R.F. and oscillator transformers are aligned at 680 and 1500 kc. With the tuning condenser plates fully meshed, line up the pointer and dial by adjusting the dial drive drum set screws so that the line at the extreme right-hand end of the dial is indicated.

Broadcast Read

With the band switch in the clockwise position, set the tuning dial to 1500 kc. Set the test oscillator at 1500 kc. and adjust the oscillator trimmer for maximum output. Next, adjust the R.F. trimmer for maximum output, taking care that the output from the test oscillator is not high enough to overload any part of the set. After these adjustments, tune the set and the test oscillator to 680 kc. Adjust the broadcast-tuning condenser for maximum output while rocking the padding condenser back and forth until maximum output is obtained. The dial setting after this adjustment may not agree exactly with the frequency, but this is not important. To complete the broadcast band line-up, repeat the adjustment at 1500 kc. as before.

Separate short-wave trimmer is provided on this receiver. The correct adjustment of the broadcast band trimmer automatically aligns the short-wave band.

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. transformer. The secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coils and padding capacitor.

The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, both of which have tuned primaries and secondaries.

The output of the I.F. amplifier is rectified by the diode section of the 6Q7 tube, providing automatic volume control, as well as detection. The audio frequency voltage developed across R-7 is applied through TC-18 to the grid of the 2A5A tube. The volume control of this tube from the variable arm of R-7, which constitutes the volume control of the receiver. The D.C. voltage developed across R-7 is applied to the control grids of the 6A8 and 6K7 tubes for automatic volume control.

The output of the 6Q7 amplifier section is resistance coupled to the grid of the 2A5A power amplifier pentode. The plate circuit of the 2A5A is initially matched to the load-speaker by means of a step-down output transformer. The tone control circuit consists of a .106-mfd. capacitor which is connected from the grid of the 2A5A tube to ground through the tone control switch. When it is desired to reduce the high frequency output of the receiver the tone control switch is closed by turning the tone control knob to the left.

When the receiver is used on alternating current, plate and grid voltages and load-speaker field current are supplied by a 2A5B rectifier tube and its associated filter circuits. Each section of the 2A5B tube acts as a separate half-wave rectifier, one for speaker field current, and the other for plate and grid voltages, each section having its own filter circuit.

When the receiver is used on a D.C. supply the 2A2A rectifier tube remains in the circuit and serves two purposes. If the power cord should be plugged in with incorrect polarity, the 2A2A tube protects the filter condensers from damage. On correct D.C. polarity the 2A2A tube aids the filter circuits in smoothing the supply, thus minimizing line noise.

The heaters of all tubes and the dial light with its shunt ballast resistor (the 30-ohm section of WR-12 and R-10) are all in series and are furnished current from the power line through a dropping resistor (the 150-ohm section of WR-12). Note that the chassis is not connected directly to either the ground lead or to the power supply, but is by-passed to the "B" lead capacitor TC-30.

ALIGNMENT PROCEDURE

Before making any adjustments in the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "tuning wand" into the antenna coil. The "tuning wand" consists of a bakelite rod having a brass cylinder non compacted into the opposite end. By inserting the brass cylinder end into the antenna coil, the inductance is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, increasing its resonant frequency. If the circuit is in exact alignment, inserting either end of the tuning wand in the coil will result in a decrease in output. When an increase in

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer RBC-609, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Tubes

The tubes used in this receiver are of the 2 volt series. All of them are of the filament or directly heated types. The filaments are connected in the series-parallel arrangement shown in Fig. 6.

Synchronous Vibrator—The action of the synchronous vibrator used in the power unit is shown in the abridged wiring diagram Fig. 7. When the switch is closed, the armature is drawn up (from the standpoint of diagram) as a result of the current through the vibrator coil. When this occurs, the upper contacts are closed and the vibrator coil is short circuited. The spring action then causes the armature to spring back and the upper contacts are opened. The vibrator coil is again energized, but the inertia of the armature causes it to continue in motion until the two bottom contacts are closed.

The spring action then brings the armature up, opening the bottom contacts. The vibrator coil is again energized and the armature is drawn up to start the next cycle.

The "A" current (heavy lines, Fig. 7) flows first through one side of the power transformer primary and then through the other side in the opposite direction. An AC voltage is induced in the secondary as a result. That portion of the armature shown in light lines rectifies the current in the secondary circuit.

Caution

Do not turn the receiver on unless ALL the tubes are in the sockets. Removal of any of them will result in abnormal voltages on the remaining tubes.

Be sure that the battery clips are connected to the battery with the correct polarity. Reversed connections may damage the receiver.

Do not use any power source other than a 6 volt storage battery.

If the receiver does not operate after being turned on, turn the switch off immediately, examine the battery connections and the fuse and see if all tubes are properly inserted.

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 2. In contact locations not used, the number applying to that particular location is not employed.

VOLTAGES AT SOCKETS

Volume Control at Maximum Antenna Shorted to Ground
Battery—6 Volts Band Switch in Standard Wave Position

- (1) Anode Grid to ground.
- (2) As read from negative filament leg to center top of R4.
- (3) As read across Resistor R4 (using 100,000 ohm meter). This voltage is subject to considerable variation depending on band and frequency setting.

Fig. 9—Dial and Drive Assembly

Voltagess

Check the voltages at the sockets to see if correct values are being delivered to the tubes. The antenna and ground should be disconnected and the antenna and ground leads from the set connected together. The volume control should be turned to the right or maximum position. The voltage chart gives the voltages with all tubes in, the speaker connected and the set in operating condition. These voltages are typical of the sets but will vary slightly with variations in individual receivers, tubes, test equipment used and battery voltage. The voltage readings are taken with a voltmeter having a resistance of 1000 ohms per volt.

Alignment, Notes

Drive Cord Data

GENERAL ELECTRIC CO.

The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator through a .1 mf. condenser to the control grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C29) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

The dial indicator should be near the 1500 KC mark on the dial scale. If it is a considerable distance from this mark, the position of the indicator on the drive cord must be changed. This procedure, however, should not be followed unless it is absolutely necessary as there is danger of breaking the clamps (See Fig. 9) which hold the indicator in place, and of fraying the drive cord. If the indicator must be moved, loosen the clamps at the back which hold it in place, and then retighten as explained in the article "Replacing Drive Cord."

Adjust the antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC padder (C34) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC. It may be necessary to increase the input signal to hear the image.

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

Adjust the oscillator Range D trimmer (C30) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range D trimmer (C3) to maximum. When adjusting this trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC (C33) padder until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Servicing Power Unit

The power unit is that portion of the chassis assembly contained within the large rectangular shield can and the circuit for which is shown within the dotted lines at the lower center of the schematic diagram, Fig. 2.

Continuity Resistance Check—The power transformer, choke coil circuits and condenser shorts may be checked by utilizing the vibrator socket terminals and various points on the "A" or "B" lines, or ground without removal of the shield can. For example: when checking the continuity or resistance of the upper half of the transformer secondary, contact may be made with the test prods at the proper vibrator socket terminal, as shown on the circuit diagram, and at the terminal strip lug to which the 18 mf. electrolytic condenser, C26 is connected.

Removing Transformer and Vibrator Socket Assembly—Take off the filter unit shield can by removing the four self tapping screws at the right side (from front) of the chassis base and the five hex nuts from the bolts at the top of the chassis.

Unsolder the ground connections from the two lugs on the inside of the chassis base (right side from front).

Now unsolder the mounting lug holding the terminal strip to the transformer cover.

Remove the four nuts from the bolts holding the transformer assembly to the chassis. Do not remove these bolts from the transformer core. Then lift the assembly to free it from the chassis so that all parts of the assembly are readily accessible.

Proceed with replacement of the power transformer or with any other necessary service or replacements and then reassemble.

Replacement of Buffer Condenser C24—This condenser is located in the top of the transformer and vibrator assembly just underneath the vibrator socket. To replace, remove the assembly as explained in the preceding article.

In addition, the two screws holding the vibrator socket to the transformer cover assembly should be taken out. The condenser is then easily replaced.

Replacing Drive Cord

Remove the chassis from the cabinet.

Remove the old drive cord, pulleys, washer and indicator.

Turn the drive drum until the slot in the rim is in the position shown in Fig. 9.

Insert one end of the drive cord in the slot and wind the cord around the drum in a clockwise direction for about two-thirds of a turn, or until it reaches the top of the drum.

Now, before putting the right pulley (from front) in place, bring the cord around the pulley from back to front so that the cord is adjacent to the celluloid dial scale; then place the pulley in position.

Extend the cord over to the left and bring it around the other pulley from front to back before placing

this pulley. Put the small brass washer on the upper shaft of the pulley and place the pulley in position as shown in Fig. 9.

Bring the cord over to the drive drum and wind it around the drum in a clockwise direction, keeping it behind the cord already on the drum.

Push the pulley tension spring in toward the drive drum so as to provide slack in the cord while the free end is being inserted into the slot in the rim.

Now mesh the condenser plates completely. Replace the celluloid indicator on the dial strip and attach it to the drive cord as shown in Fig. 9. The line on the indicator should cover the 530 KC mark on the dial scale.

Caution—When attaching the indicator to the drive cord, do not pinch the center clamp too tightly on the cord or the cord will be cut. After the clamp is pinched slightly a small amount of shellac on it will hold the cord securely.

This receiver is designed to operate from a 6 volt storage battery and uses a synchronous vibrator and a transformer to provide the required high voltage. The tubes used are of the 7 volt type. They are connected in a series-parallel arrangement across the 6 volt battery.

Two bands are covered with a tuning range in each band as shown in the specifications above. Two band coverage is accomplished by means of two sets of antenna and oscillator coils and a single section double throw switch.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna transformer and oscillator coil assemblies. The standard wave and short wave coils are indicated by the letters B and D respectively.

The band switch completes connections to the antenna transformer secondary and oscillator grid and plate coils in use. It also short circuits the antenna

Fig. 1—Location of Controls

transformer B Range secondary and oscillator B Range grid coil when it is in the D Range position.

The antenna transformer with tuned secondary feeds into a type 1C6 pentagrid converter tube which functions as the oscillator and 1st detector.

The oscillator potential on the oscillator control grid of this tube modulates the electron stream from the cathode in such a manner as to impress on it the oscillator frequency which is always 456 KC above the frequency to which the R.F. amplifier is tuned. The electron stream is also modulated at the signal frequency by the detector control grid. As a result of the beating of the two frequencies, the intermediate or beat frequency of 456 KC. is present in the plate circuit of this tube.

Two stages of I.F. amplification are employed using type 34 tubes. The primaries and secondaries of the first and second I.F. transformers and the primary of the 3rd I.F. transformer are tuned by small trimmer condensers.

A type 1B5 duo-diode triode tube functions as the second detector and a one stage audio amplifier. AVC voltage is applied through isolating resistors to the control grid circuits of the 1st detector and 1st I.F. tubes. The audio voltage developed across volume control resistor R11 is applied through the movable arm to the control grid of the 1B5 tube.

Resistance coupling is used between the 1st audio stage and the output stage which employs a 1F4 output pentode tube. A P.M. dynamic reproducer is employed.

The primary of transformer L7 serves as an audio choke in the filament circuit. The secondary of this transformer is in the control grid circuit of the 1F4, and acts as a h.v. bucking winding.

Filament Wiring—Fig. 6 is an abridged wiring diagram which shows the tube filament wiring system and also indicates the points at which the no-signal bias voltages are obtained.

Trimmers, Alignment

Fig. 1. Chassis Layout and Trimmer Locations

A 1-volt bias cell is used to supply initial bias for the 1C7G converter and the 1D5G 1st I.F. tubes which are controlled by the AVC. Do not attempt to measure the voltage of the cell with any device which draws current. The cell will last indefinitely under normal conditions. If the receiver oscillator stops functioning on the low frequency end of the "D" band, try substituting a new bias cell.

ALIGNMENT PROCEDURE

On the "D" Band (5600 to 18,000 K.C.) the oscillator operates on the low frequency side of the incoming signal; therefore, adjust the trimmer until the second oscillator peak is reached as the trimmer is increased in capacity. When the correct adjustment is made, it will be possible to tune the image of any signal on the "D" band 970 K.C. higher than the signal if the input is sufficiently high. Example: The image of 15 M.C. should be heard at 15,970 K.C.

The alignment procedure is given in table form on page 3. The "Dummy Antenna" is the capacitor or capacitor and resistor used in series with the signal generator antenna lead.

turn, provides "B" and "C" voltages. If desired, the 2-volt receiver may be converted to G.E. Power Adapter, Model BA-407, by connecting a 2-volt receiver to the storage battery, first clip in the lead to the filament accidentally. Also, be sure to separate the two clips by connecting them to opposite ends of the battery connector strap, as shown on the Power Adapter label. This avoids establishing a common path for the filament and Power Adapter supply which would result in objectionable vibrator noise. If it is difficult to snap the Power Adapter into position on the chassis, apply a little vaseline to the rubber mounting feet.

is pinched slightly, a small amount of shellac on it will hold the cord securely.

Power Supply

The chassis used in these receivers are identical except for the type of power supply employed. The 2-volt Models FB-52 and FB-56 are operated by "A", "B", and "C" batteries which are operated by a receiver by a battery cable, Stock No. BK-327. Models FB-53 and FB-57 are operated entirely by a 6-volt storage battery. Call (2 volts) of which sufficient filament current is remaining two sets (4 volts) supply the G.E. Power Adapter which, in

REPLACING DRIVE CORD

Remove the old drive cord, pulleys, washer and indicator.
 Turn the drive drum until the slot in the rim is in the position shown in Fig. 4.
 Insert one end of the drive cord in the slot and wind the cord around the drum in a clockwise direction for about two-thirds of a turn, or until it reaches the top of the drum.
 Now, before putting the right pulley (from front) in place, bring the cord around the pulley from behind to front so that the pulley is behind the indicator drum.
 Feed the cord over to the left and bring it around the other pulley from front to back before placing this pulley. Put the small brass washer on the upper shaft of the pulley and place the pulley in position as shown in Fig. 4.
 Bring the cord over to the drive drum and wind it around the drum in a clockwise direction, keeping it behind the drum already on the drum.
 Push the pulley tension spring in toward the drive drum so as to provide slack in the cord while the free end is being inserted into the slot in the rim.
 Now mesh the condenser plates completely. Reattach the drive cord as shown in Fig. 4. The indicator drum should cover the 530 K.C. mark on the dial scale.
CAUTION—When attaching the indicator to the drive cord, do not punch the center clamp too tightly on the cord or the cord will be cut. After the clamp

GENERAL ELECTRIC CO.

The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6E7 tube and two transformers, both of which have tuned primaries and secondary. Volume is controlled by the 450-ohm variable resistor, R-1, which varies the bias applied to the control grids of the 9A8 and 6E7 tubes.

The output of the I.F. amplifier is applied to the grid of the 6C5 detector which is properly biased for this service by the .1 megohm cathode resistor, R-6.

The output of the 6C5 detector is resistance coupled to the grid of the 6F6 power amplifier pentode. The plate circuit of the 6F6 is suitably matched to the loud-speaker by means of a step-down output transformer.

The tone control circuit consists of a .002 mfd. capacitor, connected in series with a two-point grounding switch, S-3, in the grid circuit of the 6F6 power pentode. When it is desired to reduce the high frequency output of the receiver, the switch, S-3, is turned to its counter-clockwise grounding position.

This and grid voltages for all tubes are supplied by the power supply system employing a 37% full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplied the required voltages and filtering action.

Trimmer adjustment after aligning the short-wave band.

(4) *Short-wave Band (1600-4000 Kc.)*

Turn the band switch to its counter-clockwise position. Set the test oscillator at 4000 kc. and tune the receiver to resonate at this frequency. No trimmer is provided for short-wave oscillator alignment. To perform the Ant. short-wave adjustment, rock the tuning condenser back and forth through resonance while adjusting the short-wave rate, trimmer, C-4, for maximum output indication on the tuning meter. It may now be necessary to readjust the broadcast band Ant. trimmer as indicated above.

Alignment of the receiver is now complete.

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. transformer, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coil. The special-cut rotor of the front condenser section permits dispensing with the usual peaking capacitor.

(Prices subject to change without notice)

(excess clockwise position). Tune the receiver to a point where no signal comes in and short-circuit the antenna and ground leads.

Connect the test oscillator output between the chassis and the control grid of the 6A8 tube. Connect the output wiper across the cone coil of the speaker. Set the test oscillator to 465 kc. and adjust the output until a small deflection is observed in the output meter.

The four I.F. trimmers, see Fig. 2, are adjusted in the following sequence:

1. Secondary trimmer on second I.F. transformer.
 2. Primary trimmer on second I.F. transformer.
 3. Secondary trimmer on first I.F. transformer.
 4. Primary trimmer on first I.F. transformer.
- Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output as the various stages are brought in line. After these adjustments have been made, the same procedure should be repeated as a final check. This I.F. alignment will then be complete.

(2) *I.F. Wave Trap*

No adjustable trimmer is provided for the I.F. trap adjustment in this receiver. The capacitor C-27, in conjunction with the inductance, L-1, automatically provides rejection of incoming I.F. signal.

(3) *R.F. Alignment*

The Ant. and oscillator trimmers are aligned at 1500 kc. First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Remove the short-circuit from the antenna and ground terminals and connect the test oscillator to raise through a dummy antenna consisting of a 400-ohm resistor in series with a 250-ohm capacitor. Connect the output indicator across the speaker cone coil.

(4) *Broadcast Band—(350-1500 Kc.)*

With the band switch in the clockwise position, set the tuning indicator to 1500 kc. Set the test oscillator at 1500 kc. and adjust the broadcast band oscillator trimmer, C-4 for maximum output. Next, set the Ant. trimmer, C-3, for maximum output, taking care that the output from the test oscillator is not high enough to overload any part of the set. No peaking adjustment is required.

To complete the broadcast band line-up, repeat the Ant.

ALIGNMENT PROCEDURE

Before making any adjustments to the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by applying a signal from the test oscillator to the receiver and inserting a tuning wand into the antenna coil. The "tuning wand" consists of a brass rod having a brass cylinder attached to one end, and a small cone of finely divided iron compressed into the opposite end. By inserting the brass cylinder end into the antenna frequency inductance, the iron filings in the coil bring the inductance to its maximum value. If the circuit is in exact alignment the test frequency of the tuning wand in the coil will result in a decrease in output. When an increase in signal will result with the iron-filled end of the wand at the 1500 kc. point on the 4.5-mc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment
Brass cylinder	Increase	Increase
Iron filings	Decrease	Decrease
Brass cylinder	Increase	Increase capacity
Iron filings	Decrease	Increase capacity
Iron filings	Increase	Increase capacity

ALIGNMENT FREQUENCIES

- I.F. Broadcast 1500 Kc.
465 Kc. Short-wave 4000 Kc.
1. A modulated test oscillator capable of producing the above alignment frequencies.
 2. An output indicator, such as a high-resistance voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
 3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
- The location of all alignment trimmer capacitors are illustrated in Fig. 2.

(1) *R.F. Alignment*

Set the frequency band switch of the receiver to the broadcast position and turn the volume control to maximum

GENERAL ELECTRIC CO.

GENERAL INFORMATION

Models FA-60 and FA-61 are compact, single-unit super heterodyne receivers employing 6 General Electric Metal Tubes and a synchronous type vibrator power supply. A 6F6 pentode output tube provides ample power for the 6 1/2-in. electrodynamic speaker. The use of an iron core antenna coil and an antenna matching trimmer, results in maximum transfer of energy from the antenna to the control grid of the 6K7 R.F. tube, providing a high signal-to-noise ratio.

The receiver chassis are housed in sturdy metal cases. To change tubes or align the receiver it is only necessary to remove the speaker cover which is secured by four snap fasteners. The chassis can be taken out of the case for servicing by removing seven self-tapping screws.

ANTENNA MATCHING SYSTEM

The design of the antenna input system makes it possible to use these receivers with either low or high capacity antennas with maximum efficiency. In general, the fish-pole under-car, built-in top, and over-top antennas are of the low-capacity type. Insulated metal top or insulated running board antennas, used in some cars, are of the high-capacity type.

The antenna male plug can be inserted into the female receptacle on the receiver in either of two positions. If the car antenna is of the low-capacity type, the plug should be inserted so that the red dots on the male plug and the receiver case are on the same side. If a high-capacity antenna is used, the red dots should be opposite each other.

The antenna coupling trimmer (C-27) should be adjusted on a weak signal between 1500 and 1600 K.C. with volume control nearly full on.

It may not be possible to "peak" the trimmer if an extremely low-capacity antenna is used. In such cases, turn the trimmer (C-27) to its maximum capacity (counter-clockwise) position, and "peak" the trimmer (C-28) on the antenna section of the gang condenser. (Antenna plug in low-capacity position).

If the antenna coupling trimmer (C-27) can be peaked with the antenna plug inserted in either position, it is recommended that the low-capacity position (red dots adjacent) be used.

In some installations, where there is not much room to work, it is advisable to adjust the antenna coupling trimmer before bolting the receiver in place.

The wiring of the antenna plugs is such that, in the low capacity position, C-27 is in series with the antenna to the high tap on the antenna coil. In the high capacity position, C-27 is in series with the antenna to the low tap on the antenna coil. These connections may be traced on the schematic diagram.

Degeneration

Audio degeneration is provided by returning a portion of the voice coil voltage of the proper phase to a section of the volume control. This is accomplished by grounding one side of the voice coil and connecting the high side of the voice coil through the capacitor (C-24) and resistor (R-23) to the resistor (R-34) which is in series with the volume control to ground.

The use of degeneration improves the frequency response and reduces non-linear distortion introduced by the audio amplifier.

ALIGNMENT PROCEDURE

In order to align these receivers properly, it is necessary to have the following test equipment:

1. A modulated test oscillator.
2. An output indicator such as a 2 to 5 volt a c voltmeter.
3. An alignment tool with a small screw driver blade.

All trimmers for aligning the receiver can be reached by removing the speaker cover. When the speaker cover is removed from the case, the field return should be made by a jumper lead between the speaker cover and case. The alignment adjustments should be made with the test oscillator output at the lowest level which will give a readable output indication.

I. F. Alignment

1. Connect an output meter across the voice coil of the loud speaker. Place a modulated 175 K.C. signal on the grid of the converter (5A8) tube through a .06 Mfd. condenser. Set the volume control at maximum and adjust the 2nd I.F. trimmer and the 1st I.F. secondary and primary trimmers in the order mentioned for maximum output. Readjust all the trimmers to insure accurate alignment.

R. F. Alignment

Attach the flexible cables to the control head and to the proper bushings on the receiver. Make sure that the control head is rigidly fastened and that its relative position in respect to the receiver will not change.

1. Adjust the scale calibration by rotating the station selector knob in a counter-clockwise direction until the low frequency end of the dial has reached its stop and the gang plates are completely meshed.

2. Set the test oscillator to 1500 K.C. with the modulation "on." Connect its output through a 250 Mfd. condenser to the prong nearest the red dot on the receiver antenna receptacle. Set the receiver dial to 160 and peak the oscillator (C-30), R.F. (C-28) and antenna (C-28) trimmers respectively (see trimmer location drawing) to give maximum deflection on the output meter.

3. Set the test oscillator to 580 K.C. and tune the receiver to this signal. Peak the 580 K.C. capacitor (C-26) while rocking the tuning condenser back and forth through resonance. Leave the peeder at the setting which gives the greatest deflection.

4. Realign the oscillator trimmer (C-30) at 1600 K.C. as in separation No. 2.

- Weight Packed..... 22 lbs.

Tuning Control Drive Ratio..... 12 to 1

INSTALLATION NOTES

several turns against the friction clutch and the dial will be set correctly.

SUPPRESSION OF IGNITION NOISE

Included with each receiver is a distributor suppressor, a generator condenser, and an ammeter condenser. When these are properly installed, the receiver should be free of ignition noise but if the interference persists, try one or more of the following suggestions:

See that the distributor contacts and spark plug points do not have too wide a gap. They should be set as recommended by the car manufacturer.

If a built-in roof antenna is used, shield the lead-in from the set up to the antenna and place an R.F. filter, consisting of a choke and condenser, in the lead to the dome light as close as possible to the point where the lead enters the corner post.

When grounding the antenna cable shield, or making any other grounds, select a point which is most effective in reducing the noise pick-up. In some cases quieter operation may be obtained by omitting the antenna-shield ground connection entirely.

Ground the motor block to the frame by means of 1/2-inch copper braid. Also ground the steering post, speedometer cable, oil gauge line, etc., to the bulkhead. It is possible that interference may be carried from the motor compartment to the receiver by these cables.

In cars with composite wood and steel bodies, it may be necessary to bend various parts together such as the instrument panel and the corner posts.

If the ignition coil is mounted on the inside of the bulkhead, it may be helped to move it to the motor side.

Wheel static interference may be overcome by installing static collector springs under the hub caps.

BATTERY POLARITY

If the receiver is being used in a car with the positive battery terminal grounded, the vibrator should be inserted so that the arrow on the label points to (+) on the vibrator top. For use with cars having the negative terminal grounded the arrow must point to (-). The receiver will not operate if the vibrator is inserted in the wrong position.

ATTACHING VOLUME CONTROL CABLE

1. Rotate the volume control fully clockwise with a screwdriver.
2. Turn the volume control knob to its extreme counter-clockwise position, then insert the flexible cable into the receiver bushing.
3. Rotate the knob fully clockwise against the slip-clutch built in the volume control. If the cable tip does not engage the slot in the volume control during the first half of its rotation, reset the volume control with a screwdriver, so that this will occur.
4. Tape both the volume and tuning control cables securely in place to prevent them from changing position.

If these instructions are followed, there will be no tendency for the switch to snap "on" due to tension in the flexible cable.

SETTING THE DIAL

The gang condenser drive is equipped with a friction clutch. After the flexible drive cables have been connected and taped securely in position, rotate the tuning knob in a counter-clockwise direction until the dial reaches its stop at the low frequency end. Continue to rotate the knob for

REPLACEMENT PARTS LIST

MODELS FA-60 AND FA-61

Insist on genuine factory-tested parts which may be purchased from authorized dealers.

I. F. ALIGNMENT WITH OSCILLOSCOPE

Band Switch Setting	Input Freq.	Point of Input	Disney Antenna	Trimmer	Comments
1. Band "B"	465 K.C. Sweep	I.F. Grid	.05 Mfd. or Larger	2nd I.F. Sec. (C-10) 2nd I.F. Pri. (C-9)	Gang condenser plates wide open—connect audio input of oscilloscope to ground and to the junction of R-3 and R-4 of the 2nd I.F. transformer—Adjust trimmers in order mentioned for a single symmetrical curve of maximum amplitude.
2. Band "B"	465 K.C. Sweep	Converter Grid	.05 Mfd. or Larger	1st I.F. Sec. (C-7) 1st I.F. Pri. (C-6)	Adjust trimmer for minimum amplitude.
3. Band "B"	465 K.C. Sweep	Antenna Post	250 Mmf. 400 ohms	Wave Trap Trimmer (C-2)	

I. F. ALIGNMENT WITH OUTPUT METER					
1. Band "B"	465 K.C. with Modulation	I.F. Grid	.05 Mfd. or Larger	2nd I.F. Sec. (C-10) 2nd I.F. Pri. (C-9)	Gang condenser plates wide open—connect output meter across voice coil—keep input signal low and volume control on as far as possible. Adjust all trimmers for maximum output
2. Band "B"	465 K.C. with Modulation	Converter Grid	.05 Mfd. or Larger	1st I.F. Sec. (C-7) 1st I.F. Pri. (C-6)	
3. Band "B"	465 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Wave Trap Trimmer (C-2)	Adjust trimmer for minimum output.

R. F. ALIGNMENT

1. Band "B"	No adjustments necessary				Close gang plates—Adjust pointer to first line at left end of tuning scale.
2. Band "C"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. trimmer (front sect. of Ant. trimmer)	Connect output meter across voice coil—tone control on "bass" position—peak trimmers for maximum output with a low input signal.
3. Band "B"	465 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. padder (gang cond.) (C-3)	Adjust padder for a maximum output meter indication in vicinity of 580 K.C. while rocking the gang condenser.

through a resistor-capacitor network consisting of C-15, R-16 and R-6 to a tap on the volume control. This feed back voltage is out of phase with the input and the resulting degeneration improves the frequency characteristic and reduces distortion. In the "bass" position, the tone control switch connects C-18 in parallel with the above network. The value of C-18 is such that more degeneration of the high than the low frequency notes occurs, thereby increasing the bass response. The "foreign" position of the switch shorts out C-15 and R-16 and places C-19 and R-6 in parallel which gives a frequency response best suited for short-wave reception. In the "speech" position, C-15 and R-16 are shorted out, C-19 is removed from the circuit, leaving R-6, thereby providing flat degeneration at all frequencies which is the most desirable condition for the reception of programs predominating in speech. The tone control switching described can be traced on the schematic diagram shown in Fig. 1.

The intermediate frequency amplifier consists of a 9K7 tube and two transformers, both of which have tuned primaries and secondaries. The output of this amplifier is applied to one plate of the 6H8 diode which is a combined detector, initial bias and automatic volume control tube. Volume is controlled by the variable potentiometer R-5 in the grid circuit of the 6F5 1st audio amplifier tube. The output of the 6F5 tube is resistance coupled to the grid of the 41 type 41 power amplifier pentode. The plate circuit of the 41 tube is suitably matched to the loud-speaker by means of a step-down output transformer.

Proper bias voltages for the various tubes are obtained by the use of a tapped bleeder circuit across the speaker field L-14. One of the cathodes of the 6H8 diode is returned to -3.1 volts on this bleeder circuit in order to provide initial bias to all the tubes controlled by the A.V.C.

Tone Control

When the tone control switch is in the "normal" position, a portion of the output voltage of the receiver is fed back

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 6700, 6000, 2400, 18,400, 15,000 and 6800 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the control grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position.

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Range C Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

6700 KC Adjustment

Set the signal generator for 6700 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C42) until maximum output is obtained. See Fig. 3 for location of this trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C10) and antenna Range C trimmer (C3) to maximum.

6700 KC Adjustment

Set the signal generator for 6700 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C42) until maximum output is obtained. See Fig. 3 for location of this trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C10) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

2400 KC Adjustment

Set the signal generator for 2400 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 2400 KC padder (C47) until the peak of greatest intensity is obtained. See Fig. 3 for location of this padder.

Range D Alignment

18,400 KC Adjustment

Set the signal generator for 18,400 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage and antenna Range D trimmers, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6800 KC Adjustment

Set the signal generator for 6800 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6800 KC padder (C45) until the peak of greatest intensity is obtained. See Fig. 3 for location of this padder.

Do not use any power source other than a 6 volt storage battery.

If the receiver does not operate after being turned on, turn the switch off immediately, examine the battery connections and the fuse and see if all tubes are properly inserted.

Servicing Power Unit

The power unit is that portion of the chassis assembly contained within the large rectangular shield can and the circuit for which is shown within the dotted lines at the lower left side of the schematic diagram, Fig. 2.

Continuity Resistance Check—The power transformer, choke coil circuits and condenser shorts may be checked by utilizing the vibrator socket terminals and various points on the "A" or "B" lines, without removal of the shield can. For example: when checking the continuity or resistance of the upper half of the transformer secondary, contact may be made with the test prods at the proper vibrator socket terminal, as shown on the circuit diagram, and at the positive terminal of the 20 mf. electrolytic condenser, C37.

Removing Transformer and Vibrator Socket Assembly—Take off the filter unit shield can by removing the four self tapping screws at the right side (from front) of the chassis base and the five hex nuts from the bolts at the top of the chassis.

Unsolder the ground connections from the two lugs on the inside of the chassis base (right side from front). Unsolder the black and white coded wire from the terminal strip lug nearest the front of the chassis. This terminal strip is mounted on the transformer cover. Now unsolder the bracket holding the terminal strip to the transformer cover.

Proceed with replacement of the power transformer or with any other necessary service or replacements and then reassemble.

Replacement of Buffer Condenser C32—This condenser is located in the top of the transformer and vibrator assembly just underneath the vibrator socket. To replace, remove the assembly as explained in the preceding article.

In addition, the two screws holding the vibrator socket to the transformer cover assembly should be taken out. The condenser is then easily replaced.

Replacing Drive Cord

Remove the chassis from the cabinet.

Lift off the dial lamp assembly and remove the old drive cord, pulleys, washer and indicator.

Turn the drive drum until the slot in the rim is in the position shown in Fig. 9.

Insert one end of the drive cord in the slot and wind the cord around the drum in a clockwise direction for about two-thirds of a turn, or until it reaches the top of the drum.

Now, before putting the right pulley (from front) in place, bring the cord around the pulley from back to front so that the cord is adjacent to the celluloid dial scale; then place the pulley in position.

Extend the cord over to the left and bring it around the other pulley from front to back before placing this pulley. Put the small brass washer on the upper shaft of the pulley and place the pulley in position as shown in Fig. 9.

Bring the cord over to the drive drum and wind it around the drum in a clockwise direction, keeping it behind the cord already on the drum.

Push the pulley tension spring in toward the drive drum so as to provide slack in the cord while the free end is being inserted into the slot in the rim.

Now mesh the condenser plates completely. Replace the celluloid indicator on the dial strip and attach it to the drive cord as shown in Fig. 9. The line on the indicator should cover the 530 KC mark on the dial scale.

Caution—When attaching the indicator to the drive cord, do not pinch the center clamp too tightly on the cord or the cord will be cut. After the clamp is pinched slightly a small amount of shellac on it will hold the cord securely.

Replace the dial lamp assembly.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer RBC-609, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Caution

Do not turn the receiver on unless ALL the tubes are in the sockets. Removal of any of them will result in abnormal voltages on the remaining tubes.

Be sure that the battery clips are connected to the battery with the correct polarity. Reversed connections may damage the receiver.

GENERAL ELECTRIC CO.

MODELS FB-72, FB-73
FB-76, FB-77

Socket, Trimmers
Alignment, Notes

GENERAL ELECTRIC CO.

Power Supply

The chassis used in these receivers are identical except for the type of power supply employed. The 2-volt Models FB-72 and FB-76 are operated by "A," "B," and "C" batteries which are connected to the receiver by a battery cable, Stock No. BK-727.

Models FB-73 and FB-77 are operated entirely by a 6-volt storage battery, 1 cell (2 volts) of which supplies filament current. The remaining two cells (4 volts) supply the G.E. Power Adapter which, in turn, provides "B" and "C" voltages.

If desired, the 2-volt receivers may be converted to 6-volt operation at any time by the addition of a G.E. Power Adapter, Model BA-407.

In connecting a 6-volt receiver to the storage battery, first clip the yellow and green leads on the battery to avoid applying excessive voltage to the filaments, accidentally. Also, be sure to separate the two clips by connecting them to opposite ends of the battery connector strap, as shown on the Power Adapter label. This avoids establishing a common path for the filament and Power Adapter supply which would result in objectionable vibrator noise.

If it is difficult to snap the Power Adapter into position on the chassis, apply a little vaseline to the rubber mounting feet.

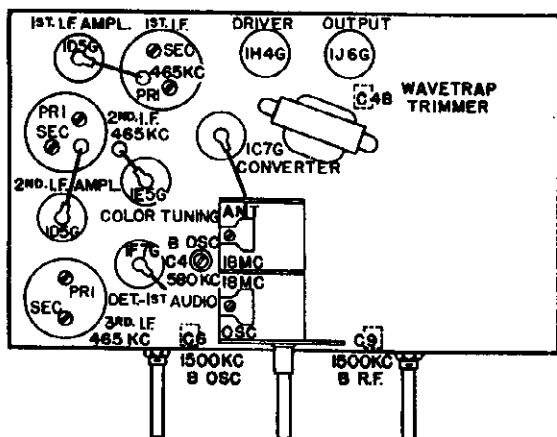

Fig. 1. Chassis Layout and Trimmer Locations

On the "D" Band (5600 to 18,000 K.C.) the oscillator operates on the *low* frequency side of the incoming signal; therefore, adjust the trimmer until the second oscillator peak is reached as the trimmer is *increased* in capacity. When the correct adjustment is made, it will be possible to tune the image of any signal on the "D" band 970 K.C. *higher* than the signal if the input is sufficiently high. Example: The image of 15 M.C. should be heard at 15,970 K.C.

The alignment procedure is given in table form on page 3. The "Dummy Antenna" is the capacitor or resistor used in series with the signal generator antenna lead.

ALIGNMENT PROCEDURE

I.F. ALIGNMENT WITH OSCILLOSCOPE

Band Switch Setting	Input Freq.	Point of Input	Dummy Ant.	Trimmer	Remarks
1 Band "B"	465 K.C. Sweep	1st I.F. Grid	.05 Mfd. or Larger	3rd I.F. Sec. (C-17) 3rd I.F. Pri. (C-18)	Gang condenser plates closed—connect audio input of oscilloscope to ground and to the diode load terminal of the 3rd I.F. transformer. Adjust the trimmers in order mentioned for a single symmetrical curve of maximum amplitude.
2 Band "B"	465 K.C. Sweep	1st I.F. Grid	.05 Mfd. or Larger	2nd I.F. Sec. (C-15) 2nd I.F. Pri. (C-16)	
3 Band "B"	465 K.C. Sweep	Converter Grid	.05 Mfd. or Larger	1st I.F. Sec. (C-13) 1st I.F. Pri. (C-14)	
4 Band "B"	465 K.C. Sweep	Antenna Post	250 Mmf. 400 ohms	Wave Trap (C-48)	

I.F. ALIGNMENT WITH OUTPUT METER

1 Band "B"	465 K.C. with Modulation	1st I.F. Grid	.05 Mfd. or Larger	3rd I.F. Sec. (C-17) 3rd I.F. Pri. (C-18)	Gang condenser plates closed—Connect output meter across Voice Coil—Keep input signal low and Volume Control on as far as possible. Adjust all trimmers in order mentioned for maximum output reading on the meter.
2 Band "B"	465 K.C. with Modulation	1st I.F. Grid	.05 Mfd. or Larger	2nd I.F. Sec. (C-15) 2nd I.F. Pri. (C-16)	
3 Band "B"	465 K.C. with Modulation	Converter Grid	.05 Mfd. or Larger	1st I.F. Sec. (C-13) 1st I.F. Pri. (C-14)	
4 Band "B"	465 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Wave Trap (C-48)	

R.F. ALIGNMENT WITH OUTPUT METER

1 Band "B"					Close gang plates—adjust pointer to first line at left end of tuning scale (530 KC).
2 Band "D"	18 M.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Oscillator (18 M.C.) Antenna (18 M.C.) See Trimmer Location View	Connect output meter across Voice Coil—tone control on "Bass" position—set osc. trimmer. While rocking the gang cond. adjust the antenna trimmer for maximum output.
3 Band "C"	No adjustments necessary				
4 Band "B"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. (C-6) Ant. (C-9)	Peak trimmers for maximum output with a low input signal.
5 Band "B"	580 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. Padder (C-4)	Adjust padder for maximum output meter indication in vicinity of 580 K.C. while rocking the gang condenser.
6 Band "B"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 Ohms	Osc. (C-6)	As in Operation No. 4.

Notes, Parts
Dial Assembly

Table listing parts and their descriptions, including items like RL-91, RP-670, RB-100, etc., with corresponding part numbers and descriptions.

In front so that the cord is adjacent to the celluloid shield...
Extend the cord over to the left and bring it around the other pulley from front to back before placing this pulley. Put the small brass washer on the upper shaft of the pulley and place the pulley in position as shown in Fig. 4.

Table with columns: Part No., Description, List Price. Lists various components like BOARD, BOARD, BOARD, etc., with their respective prices.

bulb (P-4) and the 1E5G tube and full voltage is applied to the 1H4G and 1E6C filaments. When the switch is depressed, while tuning the receiver, the parallel connected filaments of the green bulb and the 1E5G are placed in series with the filaments of the audio tubes. Due to the low resistance of the latter, most of the voltage is applied to the green bulb and it is illuminated and the audio system becomes inoperative during the tuning period. It should be noted that the battery drain is lessened during the time the switch is depressed.

REPLACING DRIVE CORD
Remove the old drive cord, pulleys, washer and indicator. Turn the drive drum until the slot in the rim is in the position shown in Fig. 4. Lay the cord in the slot and wind the cord around the drum in a clockwise direction for about two-thirds of a turn, or until it reaches the top of the drum. Now, before putting the right pulley (from front) in place, bring the cord around the pulley (from back

Fig. 4. Dial and Driver Assembly

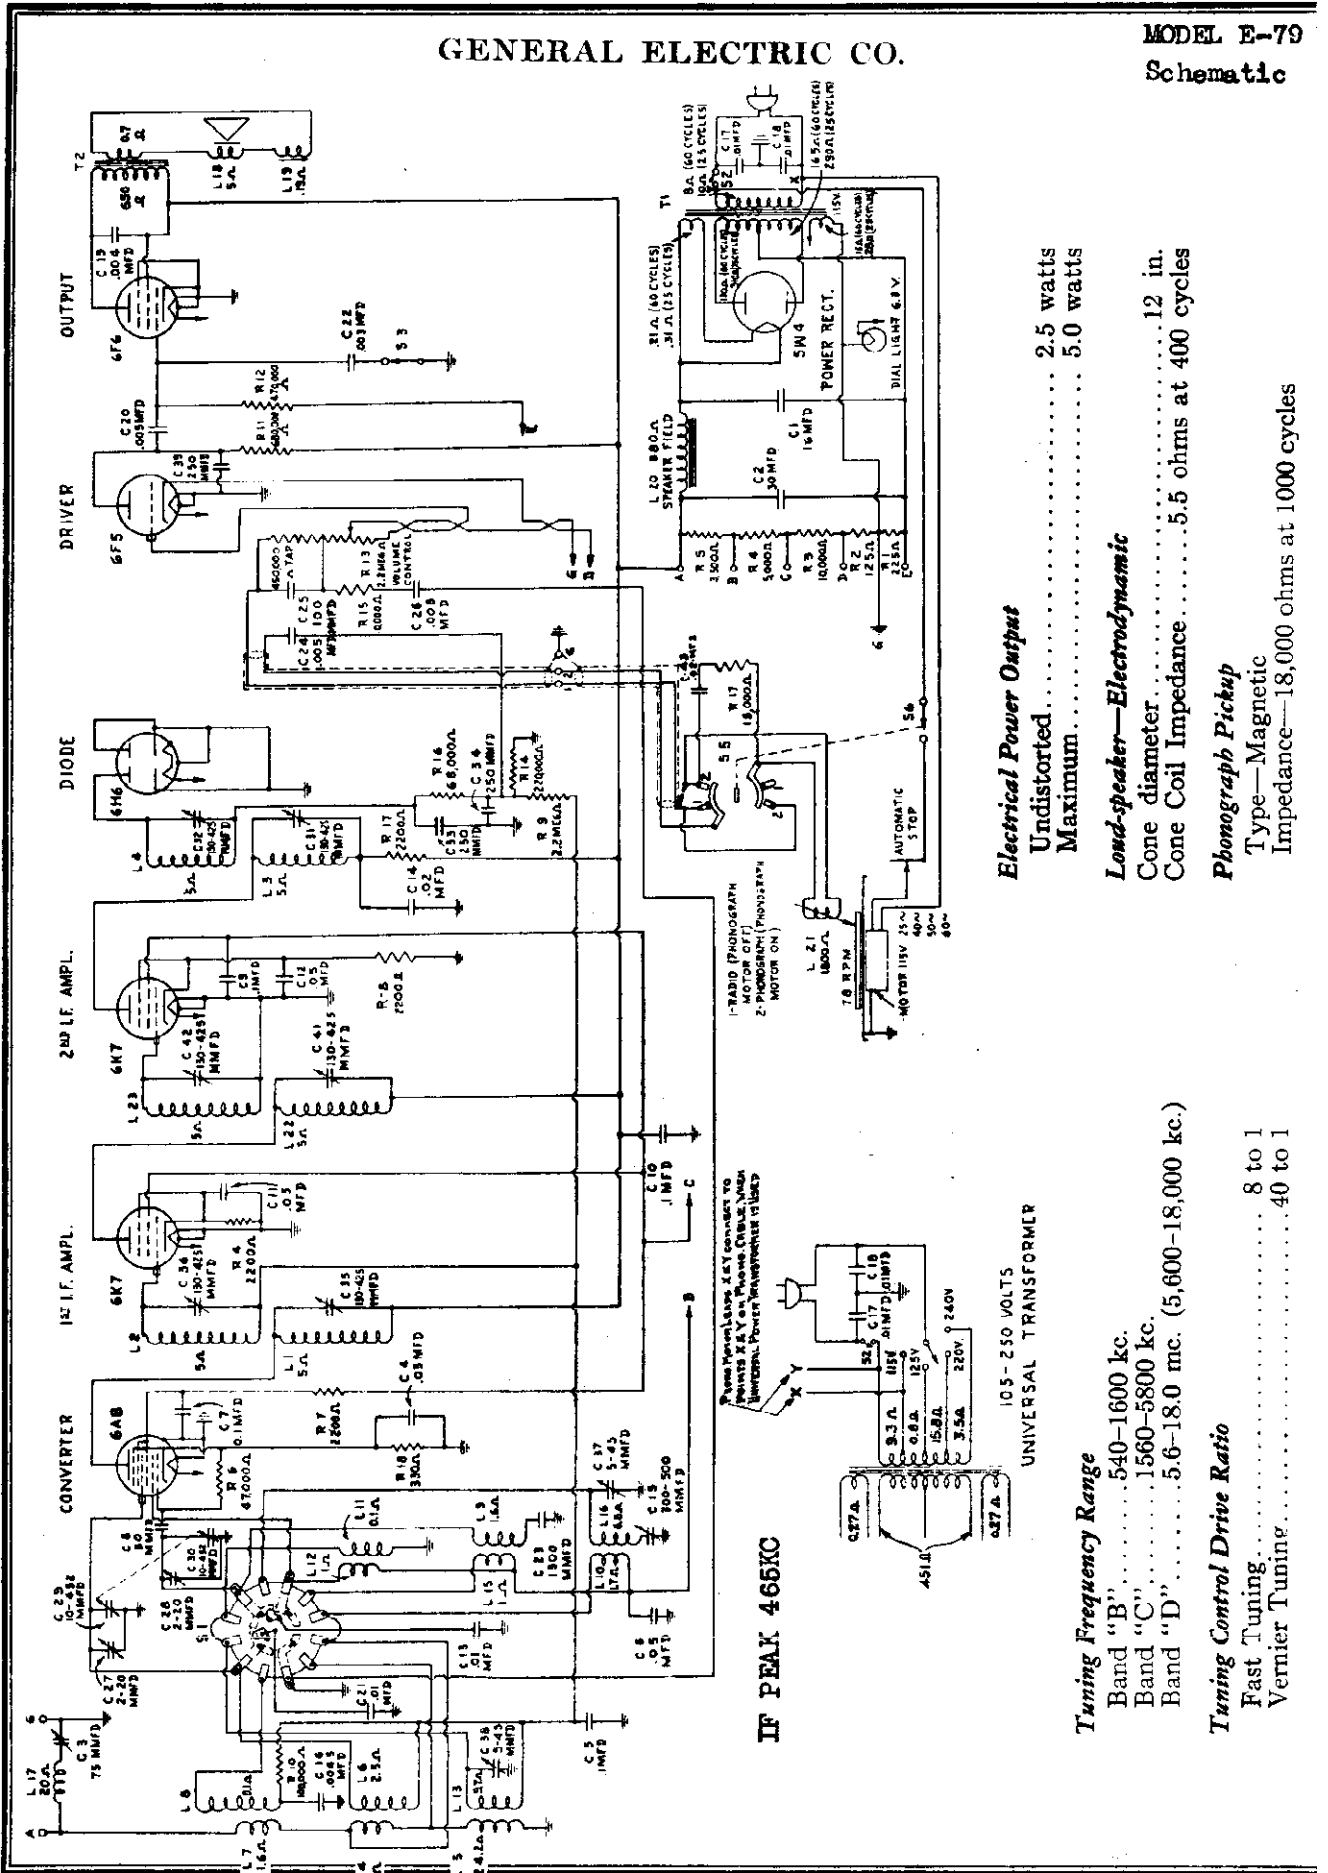

ELECTRICAL SPECIFICATIONS
Tuning Frequency Range: 540-1600 K.C.
Band 'B': 1600-3800 K.C.
Band 'D': 5600-16,000 K.C.
Maximum: 1.3 Watts
Mod. FB-72, FB-77: 2.3 Watts
Maximum: 1.0 Watts
Undistorted: 1.6 Watts
Maximum: 3-point

Diagnosis
A portion of the 1J6G output voltage is fed back to the audio input circuit through the resistor condenser network, C-49, C-29, R-3, R-11 and R-7. This feedback voltage is out of phase with the input and it serves to improve the frequency response and reduce distortion.
Greatest degeneration occurs at the lower settings of the volume control. As the volume is increased, the degeneration is reduced, making it possible to realize the full gain of the audio amplifier.

These receivers are equipped with a novel resonance indicator recently developed by General Electric. It consists of a light tuning indicator mounted on the side of the cabinet. When no signal is tuned in, the indicator will be amber in color, but as the receiver is tuned, it will change to green. Although this device is very sensitive, some signals may be too weak to cause a change to green. In such cases, the indicator will be indicated by the green portion of the indicator.
The Neon lamp and the resulting high plate current causes a voltage drop across R-20 (Fig. 2) which illuminates the Neon lamp brightly. When a signal is tuned in the AVC increases the 1E5G bias, lowers the plate current and the voltage drop across R-20, which causes the Neon lamp to go dark.
During listening periods, the silent tuning indicator S-6 shorts out the filaments of the green colorama

Circuit Data
Alignment
Dial Data

GENERAL ELECTRIC CO.

To Replace Dial Scale or Reflector
Twist the supporting tabs at either end of the scale into alignment with the slots and remove the scale and reflector. Disengage the old scale from the mounting slots in alignment. Replace scale and reflector. The bracket and wings in the inner corner of each tab over the outer edge of the slot with which it is engaged.

To Adjust the "Automatic Verifier" Drive
The vernier drive used on this receiver includes a planetary reduction unit equipped with a clutch which automatically changes the reduction ratio. This clutch consists of a sleeve mounted on the knob shaft. This engagement should take place as the sleeve slides over the locking screw and move in the end of the sleeve engages with the cam surface on the cam shaft. This engagement should take place as the knob shaft is rotated. The locking screw and sleeve should be adjusted so that the sleeve will engage the cam surface and still allow complete release of the clutch.

REPLACING COILS
In case of an open or shorted pickup coil, the pickup assembly and by study of Fig. 6. It is important that the coils be replaced as previously explained after reassembly of the receiver. Only resin core solder should be used in soldering the coil leads to the lugs.

ADJUSTMENT OF DIAL MECHANISM
The dial mechanism is rigidly mounted to the frame of the tuning condenser by means of two removable, self-lapping screws. The complete assembly is rubber-mounted on rubber cushions at the bottom of the dial mechanism consists of the following parts:
1. Dial Scale.
2. Reflector.
3. Mounting Bracket.
4. Dial Pointer Drive Cable.
5. Cable Drum (mounted on condenser shaft).
6. Vernier Drive.
7. Two 1/8" Ball-Rension Springs.

485 kc.
I. F. Band "C" 31,000 kc.
485 kc.
I. F. Band "E" 31,000 kc.
485 kc.
I. F. Band "F" 31,000 kc.
485 kc.

"D" Band (15-16.0 mc.)
Because of the R. F. circuit used in this receiver, the antenna must be aligned first. Set the frequency band switch to the "D" band position by the factor and reflector. Disengage the old scale from the mounting slots in alignment. Replace scale and reflector. The bracket and wings in the inner corner of each tab over the outer edge of the slot with which it is engaged.

"C" Band (1.5-5.0 mc.)
No separate trimmers are provided for adjustment of this band. The correct adjustment of the "D" band will automatically align the "C" band. The adjustment procedure for the "B" band follows immediately.

"B" Band (540-1600 kc.)
Set the frequency band switch to the broadcast position. Rotate the tuning condenser until the dial pointer indicates the test oscillator output. Adjust the test oscillator to the broadcast frequency (See Fig. 2). Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been properly adjusted, the antenna trimmer for maximum output. Hand adjust the antenna trimmer for maximum output. Necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to an automatic volume control action.

"A" Band (1.5-5.0 mc.)
Set the frequency band switch to the broadcast position. Rotate the tuning condenser until the dial pointer indicates the test oscillator output. Adjust the test oscillator to the broadcast frequency (See Fig. 2). Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been properly adjusted, the antenna trimmer for maximum output. Hand adjust the antenna trimmer for maximum output. Necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to an automatic volume control action.

"E" Band (1.5-5.0 mc.)
Set the frequency band switch to the broadcast position. Rotate the tuning condenser until the dial pointer indicates the test oscillator output. Adjust the test oscillator to the broadcast frequency (See Fig. 2). Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been properly adjusted, the antenna trimmer for maximum output. Hand adjust the antenna trimmer for maximum output. Necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to an automatic volume control action.

"F" Band (1.5-5.0 mc.)
Set the frequency band switch to the broadcast position. Rotate the tuning condenser until the dial pointer indicates the test oscillator output. Adjust the test oscillator to the broadcast frequency (See Fig. 2). Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been properly adjusted, the antenna trimmer for maximum output. Hand adjust the antenna trimmer for maximum output. Necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to an automatic volume control action.

Phono. Data

PHONOGRAPH

The phonograph mechanism in this receiver has been designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are explained in the following paragraphs.

MOTOR ADJUSTMENTS

The speed of the turntable motor is controlled by a governor which allows correct adjustment of the turntable rotation to 78 revolutions per minute. A pointer is provided under the turntable and the base plate is marked "F" and "S" to indicate direction to move pointer for faster or slower operation. A check of the turntable rotational speed may be made by placing a piece of paper under a record on the turntable and counting the number of times it rotates past a fixed point in one minute.

There is another type motor used in some sets of this model that does not have a speed control on the base plate. The speed of this motor is regulated by an adjustable collar on the governor. This is adjusted to 78 RPM at the factory and should not require attention.

The motor bearings and gears are properly lubricated for long operation under normal weather conditions. If the motor chatters or runs uneven, place a few drops of light machine oil on the governor felt.

TRIP MECHANISM

The trip mechanism is of simple design and consists of a latch bar connected to the motor switch and a trip lever. The latch is held closed by means of a spring between the latch bar and the trip lever. Be sure the parts work freely without binding.

The trip is actuated by an adjustable arm on the

trip lever. When the eccentric groove in the record swings the tonearm back and forth, it pushes the latch out of engagement.

MAGNETIC PICKUP

The pickup used in the phonograph is of an improved design. It is horizontally mounted in the tonearm and is held by a single set screw. The horseshoe magnet is fastened to the pole pieces by means of a set screw and clamp. The armature is centered by means of a split rubber block, which also provides a damping effect on the armature movement. The frequency response is uniform over a wide range.

Service operations which may be necessary on the pickup are as follows:

CENTERING ARMATURE

Refer to Fig. 6 showing the pickup inner structure. The armature (11) is shown in its proper relation to the magnet pole pieces, i.e., exactly centered. Whenever this centering adjustment has been disturbed, the screws (5) and (10) should be loosened and the armature rubber cushion (12) adjusted so the vertical axis of the armature is at right angles to the horizontal axis of the pole piece (8). Adjust the tension on the armature until there is a slight rocking motion. The spacing between the pole pieces and armature should be .0125 inch on each side.

DAMPING BLOCK

The top projection of the armature is imbedded in a rubber block (6) attached to the top of the pole pieces. This damping block acts as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, it may be done by removing the yoke (7).

MAGNETIZING

The loss of magnetization will not occur when the pickup has received normal care, due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong AC field, jolted or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to remagnetize the entire structure. This should be done by placing the pickup assembly on the poles of a standard pickup magnetizer and changing the pickup in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

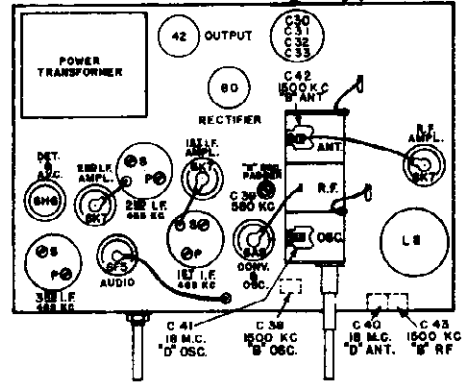

Fig. 2. Chassis Layout and Trimmer Location

ator. The grid lead should not be removed from the tube to which the input signal is applied when aligning the IF as this would remove the grid bias from the tube.

The alignment procedure is given in table form along with the trimmer location drawing, Fig. 2. A "dummy antenna" should be used in all alignments and is the capacitor or capacitor and resistor used in series with the signal generator.

Band Switch Setting	Input Frequency	Point of Input	Dummy Ant.	I.F. Alignment with Oscilloscope Trimmer	Remarks
1. Band "B"	465 K.C. Sweep	2nd I.F. Grid	.05 Mfd.	3rd I.F. Sec. (C-45) Pri. (C-44)	Gang condenser plates wide open—connect vertical input of oscilloscope to ground and the junction of R-9 and R-10 on 3rd I.F. transformer. Adjust trimmers for a single symmetrical curve of maximum amplitude. The resulting curve with input at converter grid is shown in Fig. 1.
2. Band "B"	465 K.C. Sweep	1st I.F. Grid	.05 Mfd.	2nd I.F. Sec. (C-37) Pri. (C-36)	
3. Band "B"	465 K.C. Sweep	Converter Grid	.05 Mfd.	1st I.F. Sec. (C-35) Pri. (C-34)	

I.F. Alignment with Output Meter

1. Band "B"	465 K.C. with Modulation	2nd I.F. Grid	.05 Mfd.	3rd I.F. Sec. (C-45) Pri. (C-44)	Gang condenser plates wide open—connect output meter across voice coil—keep input signal low and volume control at maximum. Adjust all trimmers in order mentioned for maximum output. Do not attempt an overall realignment after stage by stage alignment has been accomplished.
2. Band "B"	465 K.C. with Modulation	1st I.F. Grid	.05 Mfd.	2nd I.F. Sec. (C-37) Pri. (C-36)	
3. Band "B"	465 K.C. with Modulation	Converter Grid	.05 Mfd.	1st I.F. Sec. (C-35) Pri. (C-34)	

R.F. Alignment

1. Band "B"	18 M.C. with Modulation	Antenna Post	250 Mmf. 400 Ohms	Osc. (C-41) Ant. (C-40)	Close gang plates—adjust pointer to first line at left end of tuning scale.
2. Band "D"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 Ohms	Osc. (C-38) R.F. (C-43) Ant. (C-42)	Connect output meter across voice coil—tone control on "Bass" position. The image of any "D" band signal should be heard 930 K.C. above input signal when (C-41) is on proper peak. Example: 15 M.C. image—15,930 K.C. Peak (C-40) while rocking the gang condenser.
3. Band "C"	No adjustment necessary	Antenna Post	250 Mmf. 400 Ohms	Osc. (C-39)	Peak trimmers for maximum output with a low input signal.
4. Band "B"	580 K.C. with Modulation	Antenna Post	250 Mmf. 400 Ohms	Osc. (C-39)	Adjust padder for maximum output in vicinity of 580 K.C. while rocking the gang condenser.
6. Band "B"	Repeat operation 4				

MODELS F-81, F-86
Dial Data, Notes
GENERAL ELECTRIC CO.
Power Supply

The power supply consists of an 80-type rectifier, power transformer, and the associated filter system; the speaker field acting as the filter choke.

The transformers on the "A" and "C" rating receivers have two primary taps so as to accommodate a range of voltages from 110-130 volts. As shipped from the factory the receivers have the power cord connected to the 120-130-volt tap of the transformer (black and red lead). If the normal voltage of the power supply is always below 115 volts, the connection of the power cord should be removed from the lead and soldered to the 110-120-volt tap (black and yellow lead). After changing the connection, tape the soldered joint as well as the exposed end of the unused lead. This change requires removal of the chassis from the cabinet.

Speaker

Two different types of voice coil suspensions are used in both the 8- and 12-in. speakers.

The 8-in. cone assemblies are designated as early and late production and are not interchangeable. The early production voice coil suspension is $4\frac{5}{8}$ inches between points of clamping, while the later production voice coil suspension is $2\frac{3}{4}$ inches between points of clamping.

The 12-in. cone assemblies which were changed in design during production are interchangeable.

DIAL MECHANISM

The dial mechanism (Fig. 5) is rigidly mounted to the chassis by means of two brackets and four self-tapping screws. The dial pointer is operated by means of an "automatic vernier" reduction drive unit, mounted on the receiver chassis, and connected to the gang drive drum by a drive cord.

Motion imparted to the gang condenser rotor is transmitted through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail in the rear of the dial scale. The following instructions should aid you in making any repairs to this mechanism.

9 Fig. 5. Dial Drive Mechanism

Tone Control

When the tone control is in the "normal position," a portion of the output voltage of the receiver is fed back through a resistor-capacitor network consisting of C-20, R-13, and R-5 to a tap on the volume control. This feedback voltage is out of phase with the input and the resulting degeneration reduces the speaker resonance boom due to pentode output, gives an extended and relatively flat response to a wide range of low frequencies, and reduces distortion arising in the audio amplifier. In the "bass" position, the tone control switch connects C-23 in series with R-20 across the diode load resistance (R-9), reducing the high frequency response. The "foreign" position of the switch shorts out capacitor C-20 and resistor R-13 from the above network and gives a frequency response best suited for short-wave reception. In the speech position, C-20 and R-13 are shorted out; C-23 is removed from the circuit, leaving R-5; thereby providing flat degeneration at all frequencies. This is the most desirable condition for the reception of programs predominating in speech. The tone control switching described can be traced on the schematic diagram shown in Fig. 3.

To Replace Pointer Cable and Drive Cable

Remove the dial scale, allowing ready access to the dial scale mechanism.

To replace the drive cord (1), set the drive drum to the relative position as shown in Fig. 5, loop the cord through the tab on the drum, then thread it down through the hole in the chassis and around the vernier drive as indicated. The other end of the cord is looped through one end of the tension spring in back of the drive drum.

To replace the wire pointer drive cord (9), set the drive drum to the relative position as shown in Fig. 5. Loop the cord through the tab on the drum, and thread it around the drive pulley and idler pulleys and back to the tension spring on the drive drum. With the gang condenser plates fully meshed, adjust the pointer (8) along the drive cord until it coincides with the end mark at the left-hand end of the scale. The scale may be slid into place to ascertain this correct position. After final adjustment is made, solder the pointer to the wire cable (9).

To Replace Tone Control Cable

Thread the cable (6) as shown in Fig. 5 around the drive pulley (5) and around the idler pulleys, fastening the ends to the tension spring. For adjustment; turn the pulley (5) to the extreme counterclockwise, setting the pointer (7) so it extends about $\frac{1}{8}$ in. over the left-hand edge of the rail. Crimp the pointer tab on the drive cable. A final adjustment of the pointer may be made by means of the drive pulley (5) with the dial scale in place.

To Replace Volume Control Cable

Thread the cable (10) around the drive pulley (11) as shown in Fig. 5. Fasten the loops of the cable into the tension spring. To adjust, turn the control to the extreme clockwise direction and set the pointer so that the right-hand side of the pointer rider coincides with the right-hand edge of the rail. Crimp the pointer tab on the drive cable. A final adjustment of this pointer may be made by adjusting the pulley (11) on the volume control shaft after the scale has been replaced.

Band and Indicator Control

The threading and assembly of the band indicator is self-explanatory from an inspection of Fig. 5.

To "Adjust Automatic Vernier" Drive

The vernier drive used on this receiver includes a planetary reduction unit equipped with a clutch which automatically changes the reduction ratio. This clutch consists of a sleeve mounted on the knob shaft. To adjust, loosen the locking screw and move the sleeve (2) axially along the shaft until the cam surface in the end of the sleeve engages with the pin in the knob shaft. This engagement should take place at a point on the cam surface as near to the stop as possible and still allow complete release of the clutch.

To Change Dial Lamps

Dial lamps are located at either end of the dial scale assembly. Remove the dial lamp bracket from the projection at the top of the dial mechanism and replace bulb. This may be accomplished without removing the chassis from the cabinet.

Coil System

L1 is the "D" band antenna coil. The "B" and "C" band antenna coils are wound on a single coil form designated as L2 in Fig. 3. The coil L3, tuned by the center section of the gang condenser C-19 and coupled to a 6K7 tube are the essential elements of an R.F. stage, used only on the "B" band. L3 and L4 are the oscillator coils for the "D," "C," and "B" bands respectively. The antenna secondary and oscillator plate coils on the next lower frequency band to the one in use are shunted out by the wave switch contacts which are connected to C-2 and the B+ lead respectively.

The various contact terminals of the wave-change switch are numbered from 1 to 16 to facilitate the tracing of the circuit to the switch.

MODEL E-115
Colorama Data
Dial Data, Voltage

GENERAL ELECTRIC CO.

GENERAL INFORMATION

The model E-115 is a three-band superheterodyne employing eleven G.E. Metal Tubes described above. It incorporates two stages of I.F., push-pull output, three-point tone control, and a high and low volume compensated volume control. Full wave rectification is obtained from two 5W4's connected as half-wave rectifiers. L1 is the "D" band antenna coil. L2 is the "B" and "C" band antenna coil. The rear section of the gang condenser, L3, and a 6K7 tube are the essential elements of an R.F. stage, used only on the "B" band. L4 and L5 are the oscillator coils for the "D", "B", and "C" bands respectively. The antenna secondary and oscillator plate coils on the next lower frequency band to the one in use are shunted out by the wave switch contacts which are connected to C3 and B4.

Colorama Tuning

This receiver is equipped with a novel tuning device which indicates the point of exact resonance by the color of the dial illumination. When no signal is tuned-in, the dial illumination is red, but as the receiver is tuned, a smooth change to green occurs. Powerful stations will produce the darkest green color. Weak stations may only change the dial illumination to pink. The point at which any station is exactly in tune is indicated by the greatest color change obtainable. The colored light is produced by a red and a green pilot bulb mounted behind the dial scale. These are controlled by a saturable reactor in a circuit which is shown in the schematic diagram, Fig. 2. The two bulbs are placed in series across one of the secondaries on the power transformer. In shunt with the green bulb is a reactor whose impedance is varied by a d-c coil wound on the same core. The plate current of the AVC controlled tubes flows through the d-c coil. At a condition of no-signal, the bias on the AVC controlled tubes is at minimum and their plate current is at maximum causing saturation of the reactor, which in turn shunts out and nearly extinguishes the green bulb. This causes most of the a-c supply voltage to be impressed across the RED bulb and its parallel resistor. At no signal, then, the dial is deepest red. When a station is tuned-in, the above conditions are reversed and the GREEN bulb is illuminated brightly. The impedance of the reactor changes in exact relationship with the incoming signal resulting in a smooth change from red to green or from green to red.

Phase Inverter

A 6C5, used as a phase-inverter, makes it possible to use push-pull output without the use of an interstage transformer. The audio signal from the volume control is impressed on the grid of the 6C5 audio amplifier. A portion of the 6C5 output is taken from a tap on one of the 6F6 grid resistors, and impressed on the grid of the phase inverter. (The ratio of R-19 and R-20 is chosen so that the excitation on the grid of the phase inverter is equal to that applied to the grid of the 6C5 audio amplifier.) Thus, the input signal to one of the 6F6's passes through two tubes while the input to the other 6F6 passes through one tube. As a result, the excitation on the 6F6 grids is 180 degrees out of phase, which is the requirement for push-pull operation.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism, (Fig. 4) is mounted to the chassis by means of two brackets and four self-tapping screws. Motion is imparted to the gang condenser rotor through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail above the dial scale.

To Replace Drive Cable

Rotate the drive drum (14) counter-clockwise until the gang condenser plates are fully open. Place the end of the cable having an eyelet in slot (A). Thread the cable as shown in Fig. 4 making certain that the cable passes over the pin (B) and runs along the correct grooves, the looped end hooking over the tension spring (16). Check the position of the drive wheel (14) on the condenser shaft to make sure that the cable coming off the right-hand roller pulley lines up with the groove in the drive pulley. Also, as the condenser plates become fully meshed, the drive wheel (14) should just meet the bushing (D) of the reduction drive unit (13). With the drive wheel in this position, place the pointer on the rail (E) and, with the tip of the pointer (11) on the extreme left-hand dial scale division of Broadcast band, crimp the pointer tab on the drive cable.

To Adjust Pointer or Scale Calibration

Three positions of the dial pointer cable are provided on the drive drum (14) to adjust the dial pointer up or down scale. The position shown in Fig. 4 with the cable over pin (B) is the medium position. Changing the cable to the position between pins (B) and (C) moves the pointer down scale. The position below the pin (C) moves the pointer up scale from the medium position. With the gang plates closed, set the pointer at the extreme left-hand dial scale marking on the Broadcast band.

To Replace Scale

Remove the band change cable (12) by unhooking it from the fork (F) on bracket (3). Remove the end support bracket (8) held by a single self-tapping screw and withdraw the scale assembly from its housing. Replace the end caps (9) and (6) on the new scale and reassemble. Before reattaching the band change cable to the fork (F) the tension spring (7) should be given two full turns to provide proper tension for the cable.

To Adjust Rotation of Scale

The bracket arm (8) may be moved up or down by means of the set screw to give the correct position of the scale divisions with respect to the dial pointer. The pointer tip should slightly overlap the scale divisions.

To Change Dial Lamps

Lift the lamp bracket (17) from the housing (20) to which it is clipped. With the lamp bracket laid back horizontally, the lamps may be replaced.

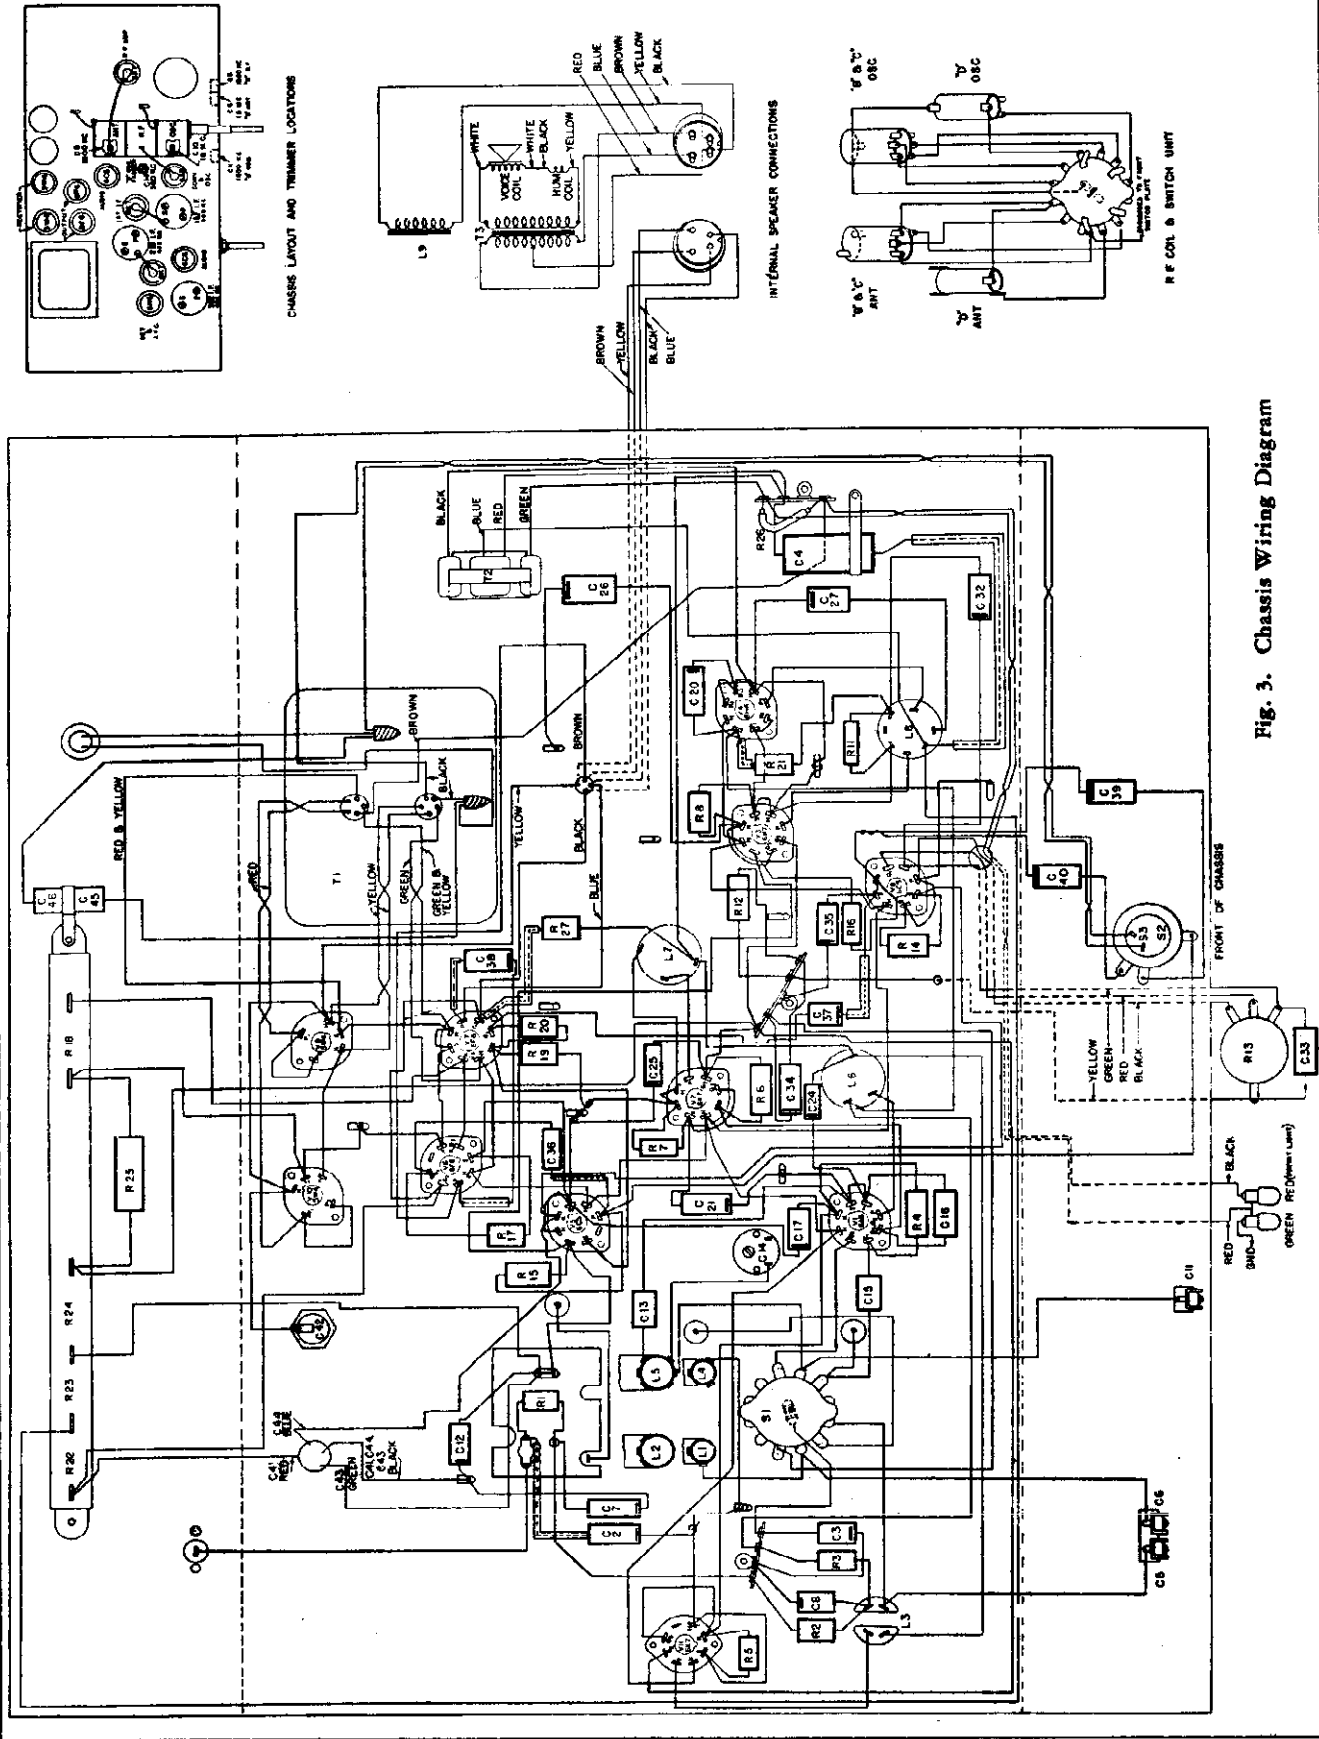

Fig. 3. Chassis Wiring Diagram

GENERAL ELECTRIC CO.

MODEL E-115
Alignment, Socket
Trimmers, Notes

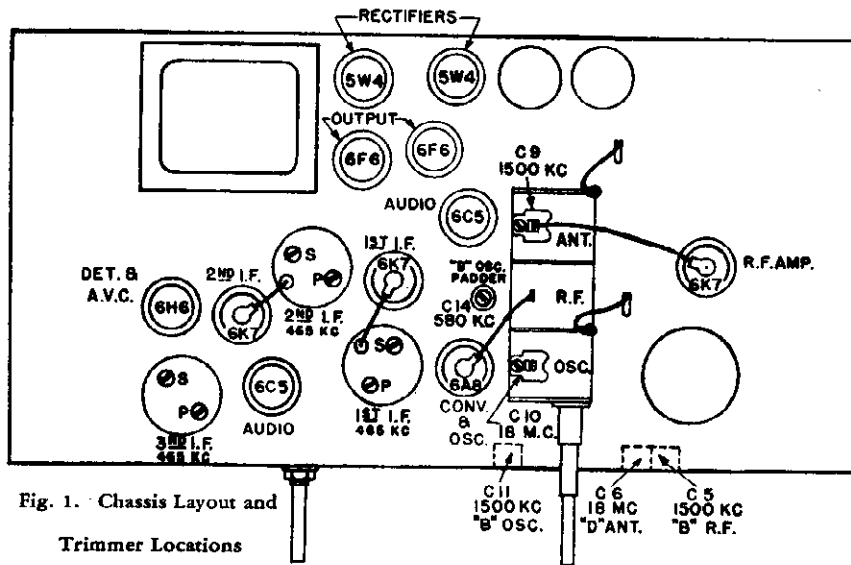

Fig. 1. Chassis Layout and Trimmer Locations

To realize all the performance built into these receivers at the factory, alignment using cathode ray equipment is to be preferred.

On the "D" band (5400 to 18,000 K.C.), the oscillator operates on the LOW frequency side of the incoming signal; therefore, adjust the oscillator trimmer until the second peak is reached as the trimmer is INCREASED in capacity. When the correct adjustment is made, it will be possible to tune the image of any signal on the "D" band 930 K.C. HIGHER than the signal if the input is sufficiently high. Example: The image of 15 M.C. should be heard at 15,970 K.C.

The alignment procedure is given in table form on page 3. The "Dummy Antenna" is the capacitor or capacitor and resistor used in series with the signal generator antenna lead.

To Change the Dial Lamps

Make certain that the copper-plated hex head shipping screw (which secures the dial lamp bracket during shipment) has been removed before attempting to remove the dial lamp bracket (No. 17). Lift the lamp bracket from the tabs under which it is clipped. Care should be taken that the lamp leads do not put an undue strain upon the drive cable. With the lamp bracket lead laid back horizontally the lamps may be placed. When the lamp bracket is reinserted care should be exercised to avoid having the lamp leads foul the gang mechanism.

Dial Notes

GENERAL ELECTRIC CO.

and the 465 kc. signal generator, it may be necessary to use a short antenna or to remove it entirely if the station is a strong local. Turn the AFC on and adjust the last I. F. as ordinary (AFC) trimmer to give zero beat. This adjustment is very critical and must be made with great care. When the adjustment is properly made, there will be no appreciable change from zero beat as the AFC switch is thrown off and on. This completes the alignment of the I. F. and AFC circuits. The alignment of the oscillator and R. F. circuits may be carried out in the usual manner. The AFC switch must remain in the "off" position.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism (Fig. 7) is rigidly mounted to the "Bentley Box" by means of two brackets and four screws. The pointer is operated by means of an "Automatic Vernier" reduction drive unit. Motion imparted to the gear condenser rotor is transmitted through a series of pulleys and an intermediate connecting cable to the dial pointer slider which is supported on a rail below the dial scale.

To Replace Cables

To replace cord or cable for the pointer or drive, the chassis should be removed from the cabinet and the dial mask (No. 14) removed from the dial scale box (No. 5). The black drive cord (No. 25) should run between the drum (No. 6) on the condenser and the drive pulley without crossing. Both the black cord (No. 25) and the bronze cable (No. 24) fasten on the same hook in the drum (No. 6) which is in front of the single lance on the outside diameter. The springs (21) and (22) are fastened on the ends of the cables after passing through the lances which are close together on the condenser drive drum. The light spring (No. 21) is on the bronze cable (No. 24) and the special spring-loop hooks into the hole in the drum next to the hook for the spring on the black cord (No. 25). The solid end of the cord or cable should be fastened first to the drum, the line should be then strung around the pulleys and drum, and lastly, the spring should be stretched into place.

To Adjust Pointer for Calibrations

The pointer (No. 37) is adjustable by removing the escutcheon plate and also the dial mask (No. 14) which is held by four screws. The screw in the center of the pointer (No. 27) can then be loosened and the pointer adjusted as needed.

To Replace Scale

The scale (No. 3) can be removed by taking off the escutcheon and the dial mask (No. 14) as for the adjustment of the pointer. The pointer (No. 27) is moved to the left-hand end, the scale is then pushed to the left and the right-hand end is pulled out with the aid of a small screw driver or a similar tool. When replacing the scale (No. 3) it is advisable to remove the cord (No. 23). The spring (No. 9) is put on the dial shaft and the shaft then inserted into the housing. The scale (No. 3), with the right-hand cap (No. 8) attached, is then inserted into the left-hand cap (No. 7) which is held in position by pushing on the shaft on the outside of the housing. After the scale (No. 3) is inserted it should be rotated from one to two times against the action of the torsion spring (No. 9). The cord (No. 23) is then replaced in the lance provided for it. It is advisable to have the band switch rotated so that the greatest length of cord possible is unwound from the lower pulley (No. 4) on the band switch shaft. It is best that the chassis be removed for the replacement of a scale. (It is important when replacing the chassis in the cabinet that the rubber grommets should be put in the chassis and not on the wood panel.)

To Adjust Reaction of the Scale

With the chassis out of the cabinet the scale (No. 3) can be adjusted to track properly on the various bands by loosening the set screw and rotating pulley (No. 4) on the band switch shaft.

Now set the test oscillator at 860 kc. and tune the receiver to resonance with this signal. Adjust the 860 kc. padding capacitor, C-26, rocking the tuning condenser back and forth through resonance at the padding capacitor, is adjusted and note the deflection of the tuning meter each time the receiver is tuned in this manner. Leave the padding capacitor set at the value which gives least deflection. Rotate the frequency dial to 465 kc. and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R. F., and antenna trimmers for maximum deflection on the tuning meter.

BAND "C" (1600-5600 KC.)

With the test oscillator connected to the receiver as above, tune the receiver until the pointer is at 6200 on the "C" band scale. Set the test oscillator for operation on this frequency and, with the volume and tone controls set as above, adjust the band "C" oscillator, R. F., and antenna trimmer, respectively (see Fig. 4), to give maximum deflection on the output meter.

BAND "D" (5.5-18.2 MC.)

Turn the band switch to Band "D." Set the test oscillator at 18,000 kc. (18.0 mc.) and tune the receiver until the pointer coincides with the 18.0 mark. Adjust the Band "D" oscillator trimmer to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17.07 mc. with the test oscillator at 18.0 mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Return the receiver to 18.0 mc. and adjust Band "D" antenna and R. F. trimmers, respectively (C-5 and C-13) for maximum output indication. When adjusting the R. F. trimmer, C-13, rock the tuning condenser back and forth through resonance as in the 860 kc. padding capacitor adjustment. Alignment of the receiver is now complete as no adjustments are provided on band "E."

4. I. F. Alignment with Output Meter

Although the use of the cathode-ray oscilloscope for alignment purposes is to be preferred, it is possible to make the I. F. trimmer adjustments with reasonable accuracy using a 465 kc. signal generator and output meter.

Place a modulated signal of 465 kc. on the grid of the last I. F. (6K7) tube with the volume control set at maximum and the AFC switch turned off. Place a low range A. C. voltmeter or other output indicator across the voice coil of the loud-speaker. Adjust the output of the signal generator so that an indication of not more than two or three volts is obtained on the output meter.

Adjust and readjust the primary trimmer for maximum output and its secondary for minimum output. This latter adjustment will be very broad. Apply the signal input to the grid of the 1st I. F. (6K7) tube and adjust both primary and secondary trimmers for maximum output, reducing the input as necessary to obtain approximately the same output indication as before. Apply the signal input to the grid of the converter (6L7) tube and adjust both primary and secondary trimmers for maximum output indication in the same manner.

It is now necessary to make a fine adjustment of the secondary trimmer of the last I. F. (AFC) transformer which is as follows: without changing the frequency of the signal generator, place the input lead on the rubber insulation of the converter (6L7) grid lead. This will provide a small signal input through the capacity between the leads. Increase the input as necessary to obtain approximately the same output indication as before. The signal generator is provided with a means of removing the input lead. This should be done. However, the adjustment may be carried out satisfactorily even with a modulated generator signal.

Now tune in any broadcast signal in the usual manner and tune the receiver carefully for zero beat between the carrier

The volume control should be in an "off" or nearly off position. Apply a frequency modulated signal to the grid of the 1st I. F. amplifier tube through a 0.05 Mcfd. (RC-072) capacitor. Connect the vertical plates of the tuning condenser between ground and the junction point between R-23 and R-24, and with the AFC switch in the "off" position proceed to align the primary and secondary of the 2nd I. F. and the AFC I. F. transformer.

The object should be to make the two curves coincide with each other at the top and throughout their length with the maximum amplitude obtainable. This will require that all four I. F. trimmers be adjusted in the usual manner *excepting* the AFC secondary (assigned and) trimmer which will be adjusted for minimum amplitude before the curves will coincide properly. Fig. 5 gives the appearance of the curves when the alignment adjustments have been completed satisfactorily on this far. Apply the same frequency modulated input to the grid of the converter (6L7) tube through a 0.05 Mcfd. capacitor as before. Adjust the primary and secondary of the 1st I. F. transformer until the curves coincide and have the appearance of Fig. 6.

A further adjustment of the A. V. C. secondary (hexagonal nut) trimmer is necessary in order to complete the I. F. alignment satisfactorily. Apply the same signal to the grid of the second I. F. amplifier tube. Unsolder the ground end of TC-48 between ground and the 6H5 cathode-prong K2 (Fig. 3) or to the center terminal of the AFC switch.

Carefully adjust the AFC secondary trimmer until a curve is obtained which is similar to that shown in Fig. 9. Correct adjustment is made when the two sides of the curve are symmetrical and intersect exactly at the horizontal axis. No adjustment of the other I. F. trimmers should be made at this time.

If a metal aligning tool is used, the curve will change when the tool is withdrawn. Therefore, it is advisable to use a fiber tool which will not change its signaling adjustment. At any rate, the final curve should be as shown with aligning tool removed.

2. I. F. Wave Trap Alignment

Leave the band switch at Band "B" and tune receiver to about 1500 kc.

With the test oscillator set at 465 kc. apply this signal to the antenna terminal through a dummy antenna consisting of a 400-ohm resistor and 200-micro. capacitor in series.

With the 465-kc. signal applied to the antenna terminal, adjust the I. F. Wave Trap Trimmer for minimum output indication.

3. R. F. Alignment

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i. e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the pointer set screw and setting the pointer to its correct position. During R. F. alignment the AFC switch must be set in its "off" (counter-clockwise) position.

BAND "B" (535-1640 KC.)

Set the test oscillator for operation at 1600 kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under "I. F. Wave Trap Alignment." Tune the receiver until the pointer is at 1600 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive antenna response. Adjust the Band "B" oscillator, R. F., and antenna trimmers respectively (location shown on Fig. 4) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which will give an easily readable output indication.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by applying a signal from Wave Trap to the coil in receiver and measuring Wave Trap into the coil in antenna. The tuning meter should be a rod of insulating material having a series of concentric metal attached to one end and small screw of finely divided iron connected to the opposite end. By inserting the metal rod end into the center of particular coil, the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer adjustment required
Metal Ring	Increase	None
Iron filings	Increase	None
Metal Ring	Increase	Increase capacity
Iron filings	Increase	Increase capacity

Alignment Frequencies

I. F.	Band "B" Band "C" Band "D" Wave Trap
465 kc.	1500 kc. 5200 kc. 18,000 kc. 465 kc.

In order to align this receiver properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with frequencies available of 465, 580, 1500, 6200, and 18,000 kc.
 2. An output indicator, such as a high resistance ac-voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
 3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
 4. A tuning wand.
- To realize the full advantage of the performance built into these receivers at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscopic method is particularly advantageous in aligning the I. F. tuned circuits.
- See Fig. 4 for location of all trimmer capacitors.

1. Visual Alignment of I. F.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I. F. alignment.

In place of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation in conjunction with the test oscillator, the response curve of the circuit under test will be then shown on the screen.

Set the tuning dial indicator at the low end of the broadcast band at some point where no signal is received, since an extraneous signal might interfere with the aligning process.

GENERAL ELECTRIC CO.

DESCRIPTION OF ELECTRICAL
CIRCUIT

Design features built into this receiver include the "Sentry Box"; separate coils for each frequency band; high efficiency converter with a separate oscillator; two stages of IP amplification for high sensitivity and selectivity; automatic volume control; automatic frequency control (AFC), silent tuning, bass and treble compensated volume control, music-speech switch operated in conjunction with a continuously variable tone control, and colorama tuning.

"Sentry Box"

The RF and oscillator sections of the receiver are contained in the "Sentry Box", which consists of a separately controlled and shielded, four band, antenna, RF and oscillator tuning unit. Individual coils are employed for each frequency range and are properly selected and connected into the circuit by the range switch. To avoid absorption effects, the range switch shorts all unused coils which might resonate at some frequency in the range being used. The section of the range switch controlling selection of the antenna coil primary also changes the antenna connection to these coils in such a manner as to maintain maximum signal transfer in each range. When the C, E, "V", Doublet Antenna System is connected to terminals "A" and "C" at the rear of the "Sentry Box", the range switch provides for the doublet operation in the short wave (D) band where this connection is advantageous, and for operation as a "T" antenna in all other bands. When a doublet antenna providing noise reduction on the broadcast band is used, it is essential that a link be connected between terminals "G" and "GR" at the back of the "Sentry Box" in order to obtain the desired action.

The antenna is coupled to the control grid of the 6K7 RF tube through the tuned antenna transformer selected by the range switch. Likewise, the output of the amplifier tube is coupled to the control grid of the 6L7 converter tube through the properly selected tuned RF transformer. The only exception to this procedure occurs when the receiver is operating on the ultra-short-wave "E" band, in which position the RF tube is disconnected from the circuit and the antenna coupled directly to the 6L7 grid through the tuned antenna transformer.

The oscillator circuit, with the exception of the ultra-short-wave "E" band, employs a 6J7 tube in a conventional tuned grid, plate feedback circuit. In the ultra-short-wave "E" band, the common impedance between the grid and plate circuits provided by the secondary of L12 in the cathode circuit of the 6K7 oscillator tube, is utilized to provide oscillation. An auxiliary feedback circuit composed of the primary of L-12 together with the capacitor, MC-29, is in the plate circuit of the oscillator tubes on the "E" band. These elements resonate slightly below the low frequency end of the "E" band and tend to improve the oscillator excitation at this end of the band. To minimize capacity effects, the tuned "E" band grid coil L-13 remains in the circuit at all times since its resistance is sufficiently low to permit this procedure. The grid coil of the broadcast "B" band oscillator returns to B plus rather than to ground in order to provide plate voltage for the 6J7 AFC tube. The 880-cc. padding capacitor, C-20, serves to isolate this voltage from the oscillator tuning condenser section. The oscillator signal which is maintained at a frequency 485 kc. higher than the incoming signal is capacity coupled to the injection grid of the 6L7 converter.

The 6J7 AFC tube is also located on the "Sentry Box" and is associated with the broadcast "B" band oscillator. A complete description of the operation of AFC is given in a later paragraph. The output of the converter is applied to the I.F. amplifier.

I. F. Amplifier

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I.F. transformers and two 6K7 amplifier tubes. Each transformer has two tuned circuits which resonate at 465 kc. The third I.F. transformer is of special construction having the primary capacitive coupled to the midpoint of the secondary in order to provide the differential AFC voltage. The operation of this transformer is discussed in a special chapter on AFC.

Detector and AVC

The plates of the 6H6 twin diode are fed in push-pull by the secondary of the third I.F. transformer. Two balanced diode loads consisting of R-24 and the series resistance of R-21, R-22 and R-23 are provided. The AFC voltage is developed across the sum of all these resistors, R-22 and R-23. The audio frequency thus provided is transferred to the A.F. system for amplification and reproduction. The direct-current component of the rectified signal produces a voltage drop across the above three resistors. That existing across R-21 and R-22 is employed for operating the 6K7 "Colorama" tuning tube. Switch S-10 permits application of either full or partial voltage to the tube, thereby preventing control of the color indication in accordance with prevailing receiving conditions. A complete description of "Colorama" tuning is given in a later paragraph. The D.C. voltage developed across R-21 is utilized for automatic volume control action by employing the same to bias the R.F. amplifier, converter, and first I.F. amplifier tubes. Initial bias for these tubes is obtained by returning resistor, R-21, to the minus 3 volt tap of the voltage divider. The second I.F. tube receives no A.V.C. and is self-biased. This minimizes the possibility of non-linear distortion on strong signals.

Audio System

The audio voltage developed across the diode load is applied to the volume control, R-32, through the isolating capacitor, TC-49. This control is compensated by means of dual resistance-capacitance networks to provide the proper balance of high and low frequencies at different volume control settings. The movable arm on the volume control selects the amount of audio signal applied to the control grid of the 6C5 audio amplifier tube and thus regulates the output of the receiver. The output of the 6C5 audio tube is transformer coupled to the control grids of the two 6B6 output tubes which operate in a push-pull connection. The music-speech control consists of a switch actuated at one extreme of the tone control rotation corresponding to that providing maximum high note response. This provides better speech clarity by decreasing the bass compensation which is accomplished by shunting capacitor, TC-83, with short-wave bands by the switch S-2; hence the music-speech control is only effective in the broadcast "B" band. Continuously variable tone control is provided by capacitor, TC-50 and variable resistor R-34 shunting the grids of the push-pull output tubes.)

Silent Tuning

Silent tuning is provided by the switch S-9 which is actuated by the tuning knob of the receiver. Pulling the tuning knob out slightly closes switch S-9 and kills the audio output by grounding the 6C5 grid. The AFC is also removed by this operation which permits a sharp indication of resonance by noting the "Colorama" light. When a station has been satisfactorily located in this manner, the tuning knob is pushed in to its original position and the switch opened.

Power Supply

D.C. power for operation of the receiver is supplied by a power supply system employing a 5Z4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

COLORAMA TUNING

These receivers are equipped with Color Tuning, a novel method which indicates approach to resonance by means of a change of color of the light illuminating the tuning scale.

The colored light is produced by a group of four red-stained pilot bulbs and a group of three green-stained bulbs behind the scale. At zero signal strength the red group is at full brilliance and the green invisibly dim. As the signal increases from zero, the red gets dimmer and the green brighter over a broad range until at extreme signal strength the green is fully bright and the red below visibility through the dial. Hence, as a station is tuned-in the color changes smoothly, and the maximum change in the green direction is an indication of resonance.

Weak stations will produce a small color change and strong stations a larger change. The difference in signal strength between the weakest and the strongest station likely to be listened to, has been found to be so great in different localities that the receivers have been equipped with a two-position sensitivity range switch for "sensitive" and "insensitive" settings of the color tuning. The switch is located near the power transformer on the chassis and may be reached from the rear of the cabinet. In the sensitive position, the weakest station to which the user can listen comfortably, above the general noise level, will shift the color to neutral white at resonance. Stronger stations give resonant points at bright green. In localities near a relatively large group of high-powered stations and having a high noise level, such as Chicago and New York, the range switch must be thrown to the insensitive position when standard outdoor antennas are used or else the color will be fixed green over so wide a band that resonance cannot be accurately found. The difference in sensitivity is about twenty to one. On short-wave bands, the band switch connects the color tuning to the sensitive setting and the switch on the chassis is insensitive. This is because practically all the short-wave signals are relatively weak. The insensitive setting is used only on the 585-1040 kc. band.

There is a group of four red and a group of three green pilot bulbs behind the scale. These are controlled by a Saturable Reactor in a circuit which is shown in the schematic diagram, Fig. 2. The saturable reactor is controlled by a D.C. coil which decreases its reactance smoothly from a high value at no D.C. to a very low value at maximum D.C. The saturable reactor acts very much like a dimming rheostat except that it is controlled by the D.C. plate current of a 6K7 tube used solely for that purpose. This tube receives for its bias a portion of the A.V.C. voltage of the set so that at no signal the bias is nearly zero. At this point, the plate current is at maximum; therefore, the red is brightest and the green invisibly dim.

SOME THINGS WHICH MAY AFFECT THE OPERATION OF COLOR TUNING ARE AS FOLLOWS:

Seven colored bulbs are used to give good diffusion of color over the scale; but if one of the seven fails, it unbalances the whole group and should be replaced immediately. The lamp socket assembly may be removed by reaching into the rear of the cabinet, pulling the lamp socket assembly up on its guides and drawing it partly out. (A shipping screw, which should be removed when the set is unpacked, may be needed to remove the first time.) There is enough slack in connecting wires to allow the assembly to be drawn forward. When the

socket assembly has been drawn far enough out for uncrewing the bulbs turn on the power switch and replace the bulbs which do not glow. All will not be bad as each group is in series (green) or series parallel (red). Take care the wires do not foul the tuning mechanism when the assembly is replaced. The colored lamps used for replacement **MUST ALL BE 6.3 VOLTS, 0.15 AMPERE LAMPS**. No other size will work.

If the red is unusually dim on no signal and the colored bulbs are all good, try removing the antenna. Next try replacing the 6K7 "Colorama" tube or replace the rectifier. Sometimes the antenna noise level is so high that it dims the red like a signal. If the tubes in the set become weak, or the set is out of alignment, or for any other reason loses its sensitivity, the color tuning will appear insensitive.

AUTOMATIC FREQUENCY CONTROL

These receivers employ automatic frequency control (AFC) which is a device for automatically controlling the oscillator frequency in such a way that, although the receiver is not exactly tuned to the signal being received, an intermediate frequency of 465 kc. will still be produced. This control of the oscillator frequency is secured by means of a 6J7 tube so connected to the oscillator that it draws a lagging current from the tank circuit and thus gives the effect of a shunt inductance. Variation of the D.C. grid bias on the 6J7 control tube will affect the mutual conductance of the tube, thereby changing the amount of lagging current drawn from the oscillator tank with a consequent effect of variation of the amount of shunt inductance connected across the oscillator coil. This alters the total inductance in the oscillator tuned circuit and changes its resonant frequency.

Grid bias for the 6J7 control tube which will vary in accordance with the amount of detuning of the receiver is obtained from the 6H6 diode rectifier operating in conjunction with its special I.F. transformer. This control voltage is the difference between the drop across resistor R-24, the load resistor for one diode section of the 6H6 diode rectifier, and the drop across resistors R-21, R-22 and R-23, which constitute the load resistance for the other diode section. When the receiver is correctly tuned to the incoming signal, the intermediate frequency produced will be 465 kc. which is the resonant frequency of the tuned circuit feeding the 6H6 diode rectifier. Under this condition each diode plate receives equal signal voltage and the D.C. voltage drops across the load resistors will be equal, giving no change in grid bias on the 6J7 control tube. If the receiver is so tuned that the intermediate frequency produced is above 465 kc. the signal voltage applied to diode plate No. 7 will exceed that applied to diode plate No. 8. In this case, the D.C. voltage drop across load resistor R-21, R-22 and R-23 will be larger than that across load resistor R-24 and a resultant voltage will be produced which will increase the 6J7 control tube grid bias lowering the mutual conductance of the tube and causing it to draw less current from the oscillator tank. This is the same effect that would be produced by increasing the amount of shunt inductance across the oscillator coil and the oscillator frequency is thereby lowered. The opposite takes place when the receiver is tuned so as to produce an intermediate frequency below 465 kc. Diode plate No. 8 then receives more signal voltage than diode plate No. 7 and the resultant voltage drop across the load resistors is such as to decrease the grid bias on the 6J7 control tube. This causes a larger current to be drawn from the oscillator tank circuit, the effect being the same as a decrease in shunt inductance which consequent increase in oscillator frequency to overcome the detuning.

MODEL E-129

Alignment

GENERAL ELECTRIC CO.

If the signal generator is provided with a means of removing the modulation, this should be done. However, the adjustment may be carried out satisfactorily even with a modulated generator signal.

Now tune in any broadcast zero beat in the usual manner and use the 485 kc. signal generator. It may be necessary to use a short antenna or to remove it entirely if the station is a strong local. Throw the AFC on zero beat, adjust the last I.F. secondary (AFC) trimmer to give zero beat. This adjustment is very critical and must be made with great care. When the adjustment is properly made, there will be no appreciable change from zero beat as the AFC switch is thrown off an on.

This completes the alignment of the I.F. and AFC circuits. The alignment of the oscillator and R.F. circuits may be carried out in the usual manner. The AFC switch must remain in the "off" position.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism (Fig. 7) is rigidly mounted to the "Bentley Box" by means of two brackets and four screws. The dial pointer is operated by means of an "Automatic Variable" reduction drive unit. Motion imparted to the gang condenser rotor is transmitted through a series of pulleys and an intermediate connecting cable to the dial pointer slider which is supported by a rail below the dial scale.

To Replace Cable

To replace cord or cable for the pointer or drive, the chassis should be removed from the cabinet and the dial mask (No. 14) removed from the dial scale box (No. 6). The black drive cord (No. 25) should run between the drum (No. 6) on the condenser and the drive pulley without crossing. Both the black cord (No. 25) and the bronze cable (No. 24) fasten on the same hook in the drum (No. 6) which is in front of the single lane on the outside diameter. The springs (31) and (32) are fastened on the ends of the cables after passing through the lanes which are close together on the condenser drive drum. The light spring (No. 21) is on the bronze cable (No. 24), and the special spring-loop hooks into the hole in the drum next to the hook for the spring on the black cord (No. 25). The solid end of the cord or cable should be fastened first to the drum, the line should be then strung around the pulleys and drum, and lastly, the spring should be stretched into place.

To Adjust Pointer for Calibration

The pointer (No. 27) is adjustable by removing the scotch-iron plate and also the dial mask (No. 14) which is held by four screws. The screw in the center of the pointer (No. 27) can then be loosened and the pointer adjusted as needed.

To Replace Scale

The scale (No. 3) can be removed by taking off the scotch-iron and the dial mask (No. 14) as for the adjustment of the pointer. The pointer (No. 27) is moved to the left-hand end, the scale is then pushed to the left and the right-hand end is pulled out with the aid of a small screw driver or a similar tool. When replacing the scale (No. 3) it is advisable to remove the cord (No. 23). The spring (No. 9) is put on the dial shaft and the shaft then inserted into the housing. The scale (No. 3), with the right-hand cap (No. 8) attached, is then inserted into the left-hand cap (No. 7) which is held in position by a screw on the shaft on the outside of the housing. After the scale (No. 3) is inserted it should be rotated from one to two turns against the action of the torsion spring (No. 9). The cord (No. 23) is then replaced in the lance provided for it. It is advisable to have the band switch rotated so that the greatest length of cord possible is unwound from the lower pulley (No. 4) on the band switch shaft. It is best that the chassis be removed for the replacement of a scale.

(It is important when replacing the chassis in the cabinet that the rubber grommets should be put in the chassis and not on the wood panel.)

side response. Adjust the Band "B" oscillator, R.F., and antenna trimmer respectively (location shown on Fig. 4) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which will give an easily readable output indication.

Now set the test oscillator at 580 kc. and tune the receiver to resonance with this signal. Adjust the 580 kc. padding capacitor, C-20, rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned in this manner. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 1600 kc. and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R.F. and antenna trimmers for maximum deflection on the tuning meter.

BAND "C" (1500-1600 KC.)

With the test oscillator connected to the receiver as above, tune the receiver until the pointer is at 1520 on the "C" band scale. Set the test oscillator for operation on this frequency and, with the volume of the controls set as above, adjust the band "C" oscillator, R.F., and antenna trimmers, respectively (see Fig. 4) to give maximum deflection on the output meter.

BAND "D" (5.18-2 MC.)

Turn the band switch to Band "D". Set the test oscillator at 18,000 kc. (18.0 mc.) and tune the receiver until the pointer coincides with the 18.0 mark. Adjust the Band "D" oscillator trimmer to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17,070 kc. with the test oscillator at 18.0 mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Retune the receiver to 18.0 mc. and adjust Band "D" antenna and R.F. trimmers, respectively (C-8 and C-13) for maximum output indication. When adjusting the R.F. trimmer, C-13, rock the tuning condenser back and forth through resonance at in the 580 kc. padding capacitor adjustment. Alignment of the receiver is now complete as no adjustments are provided on band "E".

4. I. F. Alignment with Output Meter

Although the use of the cathode-ray oscilloscope for alignment purposes is to be preferred, it is possible to make satisfactory R.F. adjustments with reasonable accuracy using a 485 kc. signal generator and output meter.

Place a modulated signal of 485 kc. on the grid of the last I.F. (8K7) tube with the volume control set at maximum and the AFC switch turned off. Place a range C, output meter or other output indicator across the volume coil of the loud-speaker. Adjust the output of the signal generator so that an indication of not more than two or three volts is obtained on the output meter.

Adjust and readjust the primary trimmer for maximum output and the secondary for minimum output. This latter adjustment will be very broad. Apply the signal input to the grid of the last I.F. (8K7) tube and adjust both primary and secondary trimmers for maximum output, reducing the input as necessary to obtain approximately the same output indication as before. Apply the signal input to the grid of the converter (6L7) tube and adjust both primary and secondary trimmers for maximum output indication in the same manner.

It is now necessary to make a fine adjustment of the secondary trimmer of the last I.F. (AFC) transformer which is as follows: without changing the frequency of the signal generator, place the input lead on the rubber insulation of the converter (6L7) grid lead. This will provide a small signal input through the capacity between the leads. Increase the attenuator setting if necessary to make the output audible.

Set the tuning dial indicator at the low end of the broadcast band at some point where no signal is received, since an excessive signal might interfere with the alignment process. The volume control should be in an "off" or nearly off position.

Apply a frequency modulated signal to the grid of the last I.F. amplifier tube through a 0.05 Mfd. (AC-075) capacitor. Connect the vertical plates of the oscilloscope between ground and the junction point between R-28 and R-24, and with the AFC switch in the "off" position proceed to align the primary and secondary of the last I.F. and the AFC I.F. trimmer.

The object should be to make the two curves coincide with each other at the top and throughout their length with the maximum amplitude obtainable. This will require that all four I.F. trimmers be adjusted in the usual manner excepting the AFC secondary (hexagonal) trimmer which must be adjusted for minimum amplitude before the curves will coincide properly. Fig. 5 gives the appearance of the curves when the alignment adjustments have been completed satisfactorily. Thus far, apply the same frequency modulated input to the grid of the converter (6L7) tube through a 0.05 mfd. capacitor as before. Adjust the primary and secondary of the last I.F. trimmer until the curves coincide and have the appearance of Fig. 6.

A further adjustment of the A.V.C. secondary (hexagonal) trimmer is necessary in order to complete the I.F. alignment satisfactorily. Apply the same signal to the grid of the second I.F. amplifier tube. Under the ground end of TC-46 and connect the vertical deflecting plates of the oscilloscope between ground and the 6B5 cathode prong K2 (Fig. 3) or to the center terminal of the AFC switch.

Carefully adjust the AFC secondary trimmer until a curve is obtained which is similar to that shown in Fig. 6. Correct adjustment is made when the two sides of the curve are symmetrical and intersect exactly at the horizontal axis. No adjustment of the other I.F. trimmers should be made at this time.

If a metal aligning tool is used, the curve will change when the tool is withdrawn. Therefore, it is advisable to use a fiber, lead-headed wrench for this aligning adjustment. At any rate, the final curve should be as shown with aligning tool removed.

2. I. F. Wave Trap Alignment

Leave the band switch at Band "B" and tune receiver to about 1600 kc.

With the test oscillator set at 485 kc. apply this signal to the antenna terminal through a dummy antenna consisting of a 400-ohm resistor and 250-microfarad capacitor in series. With the 485 kc. signal applied to the antenna terminal, adjust the I.F. Wave Trap Trimmer for minimum output indication.

3. R. F. Alignment

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i.e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the pointer set screw and setting the pointer to its correct position. During R.F. alignment the AFC switch must be set in its "off" (counter-clockwise) position.

BAND "B" (535-1640 KC.)

Set the test oscillator for operation at 1600 kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under "I.F. Wave Trap Alignment." Tune the receiver until the pointer is at 1500 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "Tuning Wand" into the coil in material having a ring of nonmagnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of a particular coil, the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled rod into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer adjustment required
Metal Ring	Decrease	None
Iron Filled	Increase	
Metal Ring	Decrease	
Iron Filled	Increase	
Metal Ring	Decrease	Decrease capacity
Iron Filled	Increase	

Alignments Frequencies

I.F. Band "B" 520 kc. Band "C" 18,000 kc. Band "D" Wave Trap 465 kc. 580 kc. 1600 kc.

In order to align this receiver properly, it is necessary to have available the following test equipment:

- A modulated test oscillator with frequencies available of 485, 580, 1500, 5250 and 18,000 kc.
- An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
- An alignment tool consisting of an insulating shaft with a small screwdriver blade.
- A tuning wand.

To realize the full advantage of the performance built into these receivers the factory circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscope method is particularly advantageous in aligning the I.F. tuned circuits.

See Fig. 4 for location of all trimmer capacitors.

I. Visual Alignment of I. F.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. The receiver can then be placed in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation. But audio modulation is not required for visual I.F. alignment.

In place of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation in conjunction with the test oscillator, the resonance curve of the circuit under test will be then shown on the screen.

GENERAL ELECTRIC CO.

should be removed when the set is unpacked, may need to be removed the first time.) There is enough slack in connecting wires to allow the assembly to be drawn forward. When the socket assembly has been drawn far enough out for unscrewing the bulbs turn on the power switch and replace the bulbs which do not glow. All will not be bad as each group is in series (green) or series parallel (red). Take care the wires do not foul the tuning mechanism when the assembly is replaced. The colored lamps used for replacement *MUST ALL BE 4 1/2 VOLTS, 0.15 AMPERE LAMPS*. No other size will work.

If there is unusually dim on no signal and the colored bulbs are all good, try removing the antenna. Next try replacing the (R-7 "Colorama") tube or replace the rectifier. Sometimes the antenna noise level is so high that it dims the red like a signal. If the tubes in the set become weak, or the set is out of alignment, or for any other reason loses its sensitivity, the color tuning will appear insensitive.

AUTOMATIC FREQUENCY CONTROL

These receivers employ automatic frequency control (AFC) which is a device for automatically controlling the oscillator frequency in such a way that, although the receiver is not exactly tuned to the signal being received, an intermediate frequency of 465 kc. will still be produced. This control of the oscillator frequency is secured by means of a 6J7 tube so connected to the oscillator that it draws a lagging current from the tank circuit and thus gives the effect of a shunt inductance. Variation of the D.C. grid bias on the 6J7 control tube will affect the mutual conductance of the tube, thereby changing the amount of lagging current drawn from the oscillator tank with a consequent effect of variation of the amount of shunt inductance connected across the oscillator coil. This alters the total inductance in the oscillator tuned circuit and changes its resonant frequency.

Grid bias for the 6J7 control tube which will vary in accordance with the amount of detuning of the receiver is obtained from the 6H6 diode rectifier operating in conjunction with its special I.F. transformer. This control voltage is the difference between the drop across resistor R-24, the load resistor for one diode section of the 6H6 diode rectifier and the drop across resistors R-21, R-22 and R-23 which constitute the load resistance for the other diode section. When the receiver is correctly tuned to the incoming signal, the intermediate frequency produced will be 465 kc. which is the resonant frequency of the tuned circuit feeding the 6H6 diode rectifier. Under this condition each diode plate receives equal signal voltage and the D.C. voltage drops across the load resistors will be equal, giving no change in grid bias on the 6J7 control tube. If the receiver is so tuned that the intermediate frequency produced is above 465 kc. the signal voltage applied to diode plate No. 7 will exceed that applied to diode plate No. 8. In this case, the D.C. voltage drop across load resistor R-21, R-22 and R-23 will be larger than that across load resistor R-24 and a resultant voltage will be produced which will increase the 6J7 control tube grid bias lowering the mutual conductance of the tube and causing it to draw less current from the oscillator tank. This is the same effect that would be produced by increasing the amount of shunt inductance across the oscillator coil and the oscillator frequency is thereby lowered by the amount necessary to compensate for the detuning. The opposite takes place when the receiver is tuned so as to produce an intermediate frequency below 465 kc. Diode plate No. 8 then receives more signal voltage than diode plate No. 7 and the resultant voltage developed across the load resistors is such as to decrease the grid bias on the 6J7 control tube. This causes a larger current to be drawn from the oscillator tank circuit, the effect being the same as a decrease in shunt inductance with a consequent increase in oscillator frequency to overcome the detuning.

by this operation, which permits a sharp indication of resonance by seeing the "Colorama" lights. When a station has been satisfactorily located in this manner, the tuning knob is pushed in to its original position and the switch opened.

Power Supply

D.C. power for operation of the receiver is supplied by a power supply system employing a 6Z4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

COLORAMA TUNING

These receivers are equipped with Color Tuning, a novel method which indicates approach to resonance by means of a change of color of the light illuminating the tuning scale.

The colored light is produced by a group of four red-stained pilot bulbs and a group of three green-stained bulbs behind the scale. At zero signal strength the red group is at full brilliance and the green invisibly dim. As the signal increases from zero, the red gets dimmer and the green brighter over a broad range until at extreme signal strength the green is fully bright and the red below visibility through the dial. Hence, as a station is tuned-in the color changes unambiguously, and the maximum change in the green direction is an indication of resonance.

Weak stations will produce a small color change and strong stations a larger change. The difference in signal strength between the weakest and the strongest station likely to be listened to, has been found to be so great in different localities that the receivers have been equipped with a two-position sensitivity range switch for "sensitive" and "insensitive" settings of the color tuning. The switch is located near the power transformer on the chassis and may be reached from the rear of the cabinet. In the sensitive position, the weakest station to which the user can listen comfortably above the general noise level, will shift the color to neutral white at resonance. Stronger stations give resonant points at high-powered stations and having a high noise level, such as Chicago and New York, the range switch must be thrown to the insensitive position. Standard outdoor antennas are used, or else the color will be fixed green over a wide band that resonance cannot be accurately found. The difference in sensitivity is about twenty to one. On short-wave bands the band switch connects the color tuning to the sensitive setting and the dial on all the short-wave signals are relatively weak. The intermediate setting is used only on the 535-1640 kc. band.

There is a group of four red and a group of three green pilot bulbs behind the scale. These are controlled by a saturable Reactor in a circuit which is shown in the schematic diagram, Fig. 2. The saturable reactor is controlled by a D.C. coil which decreases its reactance smoothly from a high value at no D.C. to a very low value at maximum D.C. The saturable reactor acts very much like a dimming rheostat except that it is controlled by the D.C. plate current of a 6K7 tube used solely for that purpose. This tube receives for its bias portion of the A.V.C. voltage of the set so that at no signal the bias is nearly zero. At this point, the plate current is at maximum; therefore, the red is brightest and the green invisibly dim.

SOME THINGS WHICH MAY AFFECT THE OPERATION OF COLOR TUNING ARE AS FOLLOWS:

Seven colored bulbs are used to give good diffusion of color over the scale; but if one of the seven fails it unbalances the whole group and should be replaced immediately. The lamp socket assembly may be removed by reaching into the rear of the cabinet, pulling the lamp socket assembly up on its guides and drawing it partly out. (A shipping screw, which

The 6J7 AFC tube is also located on the "Sentry Box" and is associated with the broadcast "B" band oscillator. A complete description of the operation of AFC is given in a later paragraph. The output of the converter is applied to the I.F. amplifier.

I. F. Amplifier

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I.F. transformers and two 6K7 amplifier tubes. Each transformer has two tuned circuits which resonate at 465 kc. The third I.F. transformer is of special construction having the primary capacitor coupled to the midpoint of the secondary in order to provide the differential AFC voltage. The operation of this transformer is discussed in a special chapter on AFC.

Detector and AVC

The plates of the 6H6 twin diode are fed in push-pull by the secondary of the third I.F. transformer. Two balanced diode loads consisting of R-24 and the series resistance of R-21, R-22 and R-23 are provided. The AFC voltage is developed across the sum of all these resistors, while the audio voltage appears across the sum of R-21 and R-22 and R-23. The audio frequency thus provided is transferred to the A.F. system for amplification and reproduction. The direct-current component of the rectified signal produces a voltage drop across the above three resistors. That existing across R-21 and R-22 is employed for operating the 6K7 "Colorama" tuning tube. Switch S-10 permits application of either full or partial voltage to the tube, thereby permitting receiving conditions. A complete description of "Colorama" tuning is given in a later paragraph. The D.C. voltage developed across R-21 is utilized for automatic volume control action by employing the same to bias the R.F. amplifier, converter, and first I.F. amplifier tubes. Initial bias for these tubes is obtained by returning resistor R-21 to the minus 3 volt tap of the voltage divider. This second I.F. tube receives no A.V.C. and is self-biased. This minimizes the possibility of non-linear distortion on strong signals.

Audio System

The audio voltage developed across the diode load is applied to the volume control, R-30, through the isolating capacitor, TC-49. This control is compensated by means of dual resistance-capacitance networks to provide the proper balance of high and low frequencies at different volume control settings. The movable arm on the volume control selects the amount of audio signal applied to the control grid of the 6C5 audio amplifier tube and thus regulates the output of the receiver. The output of the 6C5 audio tube is transformer coupled to the control grids of the two 6F6 output tubes which operate in a push-pull connection.

The music-speech control consists of a switch actuated at one extreme of the tone control rotation corresponding to that providing maximum high note response. This provides better speech clarity by decreasing the bass compensation which is accomplished by shunting capacitor TC-53 with TC-52. The bass compensation is removed entirely on the short-wave bands by the switch S-2; hence the music-speech control is only effective in the broadcast "B" band. Continuously variable tone control is provided by capacitor TC-49 and variable resistor R-34 shunting the grids of the push-pull output tubes.

Silent Tuning

Silent tuning is provided by the switch S-9 which is actuated by the tuning knob of the receiver. Pulling the tuning knob out slightly closes switch S-9 and kills the audio output by grounding the 6C5 grid. The AFC is also removed

DESCRIPTION OF ELECTRICAL CIRCUIT

Model E-129 is a 12 metal tube receiver using a highly sensitive and selective superheterodyne circuit. In addition to the fundamental requirements of superheterodyne design it incorporates many noteworthy technical improvements which are of definite advantage in improving efficiency of performance and ease of operation.

Design features built into this receiver include the "Sentry Box"; separate coils for each frequency band; high efficiency converter with a separate oscillator; two stages of I.F. amplification for high sensitivity and selectivity; automatic volume control; automatic frequency control (AFC); silent tuning, bass and treble compensated volume control, music-speech switch operated in conjunction with a continuously variable tone control, and colorama tuning.

"Sentry Box"

The RF and oscillator sections of the receiver are contained in the "Sentry Box" which consists of a separately contained and shielded, four band, antenna, RF and oscillator tuning unit. Individual coils are employed for each frequency range and are properly selected and connected into the circuit by the range switch. To avoid absorption effects, the range switch shorts all unused coils which might resonate at some frequency in the range being used. The section of the range switch controlling section of the antenna coils in such a manner as to insure maximum signal transfer in each range. When the O.B. "v" Doubtless Antenna System is connected to terminals "A" and "G" at the rear of the "Sentry Box," the range switch provides for true doublet operation in the short wave (D) band where this connection is advantageous, and for operation as a "T" antenna in all other bands. When a doublet antenna providing noise reduction on the broadcast band is used, it is essential that a link be connected between terminals "C" and "CR" at the back of the "Sentry Box." In order to obtain the desired action.

The antenna is coupled to the control grid of the 6K7 RF tube through the tuned antenna transformer selected by the range switch. Likewise, the output of the amplifier tube is coupled to the control grid of the 6L7 converter tube through the property selected tuned RF transformer. The only exception to this procedure occurs when the receiver is operating on the ultra-short-wave "F" band, in which position the RF tube is disconnected from the circuit and the antenna coupled directly to the 6L7 grid through the tuned antenna transformer.

The oscillator circuit, with the exception of the ultra-short-wave "E" band, employs a 9J7 tube in a conventional tuned grid, plate feedback circuit. In the ultra-short-wave "E" band, the common impedance between the grid and plate circuits provided by the secondary of L12 in the cathode circuit of the 6K7 oscillator tube, is utilized to provide oscillation. An auxiliary feedback circuit composed of the primary of L-12 together with the capacitor, MC-29, is in the plate circuit of the oscillator tubes on the "E" band. These elements resonate slightly below the low frequency end of the "E" band and tend to improve the oscillator excitation at this end of the band. To minimize capacity effects, the tuned circuit of the 6K7 oscillator tube, is in the circuit at all times since its reactance is sufficiently low to permit this procedure. The grid coil of the broadcast "B" band oscillator plate voltage for the 6J7 AFC tube. The 580-kc. padding capacitor, C-20, serves to isolate this voltage from the oscillator tuning condenser section. The oscillator signal which is maintained at a frequency 465 kc. higher than the incoming signal is capacity coupled to the injection grid of the 6L7 converter.

MODEL E-129
Phonograph Data

GENERAL ELECTRIC CO.

Fig. 8. Automatic Record Changer Mechanism

Fig. 9. Piano Electric Crystal Pick-up

The oval head machine screw, which serves as a pivot at the right-hand end of the lift lever (L), should be set at such a height to allow the lift lever to be raised by the latch bar and so the roller is able to pass under the end of the lift lever without binding and also without too much clearance.

Unloading Mechanism

The record changer is intended to be operated with at least one record on the turntable in order to prevent the needle from damaging the turntable coating.

This motor mounting screws (C) should be adjusted so that the depression of the leverable from the base plate to the top of one record is one inch.

The set screw and lock nut on the projecting member under the record removing arm (A) is provided for adjusting the elevation of the record separating and lifting finger. This screw should be adjusted so that the finger will remove the second record on the table but barely rise over, and not remove, the first record.

Record Lift Adjustments

To adjust the lift of a record while removing it from the turntable shaft and table the latch bar (I) should be placed in a position at its farthest protrusion toward the front of the arm mounted on the motor spindle. Place a record on the turntable separating finger and lever (A), the other side of the changer holds it while removing it. Let the other Adjust the lift by means of the eccentric head and nut (P) in the left of the record removing assembly until the center side of the record is off the turntable shaft and swings free of it.

Tone Arm Lowering

To adjust for the proper lowering of the tone arm on the edge of a 10-inch record (the difference for the 12-inch record is adjusted at the factory) the screw above the shelf on the right side of the tone arm is provided for moving the tone arm stop right or left until the needle will lower to approximately 1/8 in. from the edge of the record.

To adjust the proper vertical clearance of the tonearm's vertical pivot bearing, two jam nuts are provided on the end of the pivot sleeve, under the changer base plate. These nuts may be adjusted to take up unnecessary play.

Dash Pot Adjustment

Place the tonearm of the record changer in the position which results when the latch bar (I) is against the turntable motor cam at its furthest operating throw. (This position is the other extreme of the operating cycle as shown on Figure 8.) The tonearm stop should be against the cone-shaped cup of the dash pot, while in the 18-inch position.

Raise or lower the dash pot plunger by means of the two lock nuts which control the lift of the dash pot lever under the changer base plate. Adjust these two nuts so that there is a clearance of a post card thickness between the dash pot leather tip and the under-side of the tonearm shaft.

Lowering Speed of Dash Pot

The top of the dash pot is provided with a knurled screw cap for adjusting the lowering speed of the dash pot. In case the lowering speed is too fast, put a drop of light machine oil on this change above this cap and allow it to work into the felt packing gland. Tighten or loosen this cap to obtain the desired lowering speed.

Crystal Pick-up

The pick-up used in the phonograph unit is of the piezo-electric crystal type. The crystal cartridge (4), Fig. 9, is a factory sealed unit and no adjustments are provided. The pick-up and tonearm assembly should require very little servicing and if treated with reasonable care should perform its function without attention for long periods of time.

AUTOMATIC RECORD CHANGER

The record-changing mechanism used in this receiver has been designed to be simple and fool-proof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are explained in the following paragraphs. It is important when servicing the automatic record changer to have it placed on a level support. It is also important to refrain from forcing the mechanism if there is a tendency to bind or jam, since bent levers and possibly broken parts may result.

Operating Instructions and Service Adjustments

The record changer is designed to automatically play eight 10-inch or seven 12-inch standard 78 RPM phonograph records on one side. The last record remains on the turntable and repeats until most records are placed on the turntable or the mechanism is stopped.

To play 12-inch records, referring to Figure 8, pull the thumb stop (K) on the right-hand side of the tonearm forward, which allows the needle to locate on the edge of the record, also push the knob (D) at the left rear corner of the changer from 10 inch to 12 inch as marked on the base plate. Either 10-inch or 12-inch records may be repeated as often as desired by lifting the record removing arm (A) to an upright position.

To reject a record from the turntable while playing, pull the lever (L) at the right side of the turntable.

Motor Adjustments

The speed of the turntable motor is controlled by a governor which allows correct adjustment of the turntable rotation to 78 revolutions per minute. A pointer is provided, under the turntable and the base plate is marked "p. 78" to indicate direction to move pointer for faster or slower operation. A check of the turntable rotational speed may be made by placing a piece of paper under a record on the turntable and counting the number of times it rotates past a fixed point in one minute.

The motor bearings and gears are properly lubricated for long operation under normal weather conditions. If the motor chatters or runs uneven, place a few drops of light machine oil on the governor felt.

Trip Mechanism

While playing a record, the tonearm lifting mechanism (L) and the record removing arm (A) are held out of engagement with the motor cam by means of a latch which is formed by the vertical square pin in the pointed latch lever (I) and the notch in the side of the tonearm lift lever (L). This pin should engage the notch approximately one-half its depth, and is adjusted thus by means of an eccentric washer and screw in the trip lever (B) upon which is mounted the eccentric block (H).

The latch is held closed by means of a spring between the latch bar and the trip lever. Be sure the parts work freely without binding so that they will latch when the latch bar swings back past the notch after a record has been removed.

The record changer is designed to trip on an eccentric trip groove record. The eccentric trip is effected by means of a hardened steel pin which is pressed into the top of the tonearm lift crank. This pin ratchets over the top of the grooves in the eccentric block (H) on the trip lever (B). When the eccentric groove in the record swings the tonearm back and forth it pushes the latch out of engagement. Care should be taken to insure that there is at least 1/8 in. clearance for the end of the pin to raise over the ratchets to provide the ratchet action, when using a short phonograph needle riding on top of one record on the turntable.

MODEL E-155
Circuit Data

GENERAL ELECTRIC CO.

The rear of the cabinet. In the sensitive position, the weakest station to which the user can listen comfortably above the general noise level, will shift the color to neutral white at resonance. Stronger stations give bright green indications at resonance. In localities near a relatively large group of high-powered stations and having a high noise level, such as Chicago and New York, the range switch must be thrown to the insensitive position when standard out-door antennas are used, or else the color will be fixed green over so wide a range that resonance cannot be accurately found. The difference in sensitivity is about twenty to one. On short-wave bands the band switch connects the color tuning to the sensitive setting and the switch on the chassis is inoperative. This is because practically all the short-wave signals are relatively weak. The insensitive setting is used only on the 540-1920 kc. band.

There is a group of four red and a group of three green pilot bulbs behind the scale. These are controlled by a Saturable Reactor, L-22, in a circuit which is shown in the schematic diagram, Fig. 2. The saturable reactor is controlled by a D.C. coil which decreases its reactance smoothly from a high value at no D.C. to a very low value at maximum D.C. The saturable reactor acts very much like a dimming rheostat except that it is controlled by the D.C. plate current of the 6K7 tube used solely for that purpose. At this point the plate current is at maximum; therefore, the red is brightest and the green is dimmest.

Some things which may affect the operation of color tuning are as follows:

Seven colored bulbs are used to give good diffusion of color over the scale; but if one of the seven fails it unbalances the whole group and should be replaced immediately. The lamp socket assembly may be removed by reaching into the rear of the cabinet, pulling the lamp socket assembly up on its guides and drawing it partly out. A shipping screw, which should be removed when the set is unpacked, may need to be removed the first time. There is enough slack in connecting wires to allow the assembly to be drawn forward. When the socket assembly has been drawn far enough out for unscrewing the bulbs, turn on the power switch and replace the bulbs which do not glow. All will not be bad as each group is in series (green) or series parallel (red). Take care the wires do not foul the tuning mechanism when the assembly is replaced. The colored lamps used for replacement must all be 6.3 volts 0.15 ampere lamps. No other size will work.

If the red is unusually dim on no signal and the colored bulbs are all good, try removing the antenna. Next try replacing the 6K7 colorama tube, or replace the rectifier. Sometimes the antenna noise level is so high that it dims the red color like a signal. If the tubes in the set become weak, or the set is out of alignment, or for any other reason, loses sensitivity the color tuning will appear insensitive.

The output of the 6G5 first audio tube is resistance coupled to the control grid of the 6V6 second audio amplifier which is connected for triode operation. The output of this stage is transformer coupled to the control grids of the two 6L6 output tubes operating in a push-pull connection. The push-pull output stage is coupled to the loud-speaker through an impedance matching output transformer.

Degeneration

Audio degeneration is provided by applying a portion of the voice coil voltage to the cathode circuit of the 6V6 audio driver. This connection tends to flatten out the frequency characteristic of the audio and reproducing systems and decreases hum and non-linear distortion introduced by the audio amplifier.

The music-speech control consists of a switch actuated at one extreme of the tone control rotation corresponding to that providing maximum high note response. This provides better speech clarity by decreasing the bass compensation which is accomplished by shunting capacitor TC-56 with TC-57. The bass compensation is removed entirely on the short-wave and "A" bands by the switch S-2; hence the music-speech control is only effective in the broadcast (B) band. Continuously variable tone control is provided by capacitor TC-68 and a variable resistor R-38 shunting the grids of the push-pull output tubes.

Silent Tuning

Silent tuning is provided by the switch S-9 which is actuated by the tuning knob of the receiver. Pulling the tuning knob out closes the switch S-9 and silences the audio output by grounding the 6V6 control grid. The AFC is also removed by this operation which permits a sharp indication of resonance by noting the Colorama lights. When a station has been satisfactorily located in this manner, the tuning knob is pushed into its original position and the switch opened.

Power Supply

D. C. power for operation of the receiver is supplied by two 6Z4 tubes each operating as a half-wave rectifier. The output of the rectifiers is fed through a two-section filter tuning substantially pure D. C. to the voltage divider system from which taps supply correct voltages to the various receiver circuits.

Colorama Tuning

These receivers are equipped with Colorama Tuning, a novel method which indicates the approach to resonance by means of a change in the color of the light illuminating the tuning scale.

The colored light is produced by a group of four red-stained pilot bulbs and a group of three green-stained bulbs behind the scale. At zero signal strength the red group is at full brilliance and the green faintly dim. As the signal increases from zero, the red goes dimmer and the green brighter over a broad range until at extreme signal strength the green is fully bright and the red below visibility through the dial. Hence, as a station is tuned in the color changes smoothly, and the maximum change in the green direction is an indication of resonance.

Weak stations will produce a small color change and strong stations a larger change. The difference in signal strength between the weakest and the strongest station likely to be listened to, has been found to be so great in different localities that the receivers have been equipped with a two-position sensitivity range switch for "sensitive" and "insensitive" settings of the color tuning. The switch is located on the chassis near the power transformer and may be reached from

frequency 465 kc. higher than the incoming signal, is expected to be coupled to the injection grid of the 6L7 converter.

The 6I7 AFC tube is also located on the "Sentry Box" and is associated with the broadcast "B" band oscillator. A complete description of the operation of AFC is given in a later paragraph. The output of the converter is applied to the I. F. amplifier.

I. F. Amplifier

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformer and two 6K7 amplifier tubes. Each transformer has two tuned circuits which resonate at 465 kc. The third I. F. transformer is of special construction having a primary capacitor coupled to the midpoint of the secondary in order to provide the differential AFC voltage. The operation of this transformer is discussed in a special section on AFC.

Detector and AVC

The plates of the 6I6 twin diode are fed in push-pull by the secondary of the third I. F. transformer. Two diode loads consisting of R-24 and the series resistance of R-21, R-22, and R-23 are provided. The AFC voltage is developed across the sum of all these resistors, while the audio voltage appears across the sum of R-21, R-22, and R-23. A portion of the audio frequency thus provided is transferred to the A. F. system for amplification and reproduction. The direct current component of the rectified signal produces a voltage drop across the above three resistors. This voltage is employed to operate the 6K7 "Colorama" tuning tube. Switch S-11 permits the application of either full or partial voltage to the tube, thereby permitting control of the color indication in accordance with prevailing receiving conditions. A complete description of "Colorama" tuning is given in a later section. The D.C. voltage developed across R-21 and R-22 is utilized for automatic volume control action by employing the same to bias the R. F. amplifier, converter, and first I. F. amplifier tubes.

Initial control grid bias for these tubes is supplied by the delay bias diode under conditions of little or no signal. Under such conditions, this diode draws current through resistors R-21, R-22, and R-23, thereby maintaining the desired operating bias. When signal voltage above the level of the initial bias is applied, this diode ceases to draw current and the AVC diode takes over the biasing function.

The second I. F. tube receives no AVC and is self-biased. This minimizes the possibility of non-linear distortion on strong signals.

Noise Limiter

The other diode section of the auxiliary twin diode is employed as a transient noise-limiting device. This diode is so connected that its normal D. C. plate voltage has a value greater than the peak voltage of the audio signal applied through it to the manual volume control. Any transient signal of high voltage such as a static impulse will drive the plate negative, rendering the diode non-conducting and limiting the amount of transient voltage developed across the volume control.

Audio System

The manual volume control consists of a tapered potentiometer connected between the noise-limiting diode and the control grid of the 6G5 first audio amplifier. This control is tone-compensated by means of a resistance-capacitance network to provide proper balance of high and low notes at different volume control settings.

DESCRIPTION OF ELECTRICAL CIRCUIT

Model E-155 is a 15 metal tube receiver using a highly sensitive and selective superheterodyne circuit. In addition to the fundamental requirements of superheterodyne design it incorporates many noteworthy technical improvements which are of definite advantage in improving efficiency of performance and ease of operation.

Design features built into this receiver include the "Sentry Box"; separate coils for each frequency band; high efficiency converter with separate oscillator; two stages of I. F. amplification for high sensitivity and selectivity; automatic volume control; automatic frequency control (AFC); noise limiter; silent tuning; bass and treble compensation volume control; music-speech switch operated in conjunction with a continuously variable tone control; push-pull beam power tube output; audio degeneration; extra large electrodynamic speaker; and colorama tuning.

"Sentry Box"

The R. F. and oscillator sections of the receiver are contained in the "Sentry Box" which consists of a separately contained and shielded, five band antenna-R. F. oscillator tuning unit. Individual coils are employed for each frequency range and are properly selected and connected into the circuit by the range switch. To avoid absorption effects, the range switch starts all unused coils which might resonate at some frequency in the band being used. The section of the range switch controlling selection of the antenna coil primary also changes the antenna connection to these coils in such a manner as to insure maximum signal transfer in each range. When the G-E "Y" Double Antenna System is connected to terminals "A" and "G" at the rear of the "Sentry Box," the range switch provides for true doublet operation in the short wave "D" band where this connection is advantageous, and for operation as a "T" antenna in all other bands. When a doublet antenna providing noise reduction on the broadcast band is used, it is essential that a link be connected between terminals "G" and "GR" at the back of the "Sentry Box" in order to obtain the desired action.

The antenna is coupled to the control grid of the 6K7 R. F. tube through the tuned antenna transformer selected by the range switch. Likewise, the output of the R. F. amplifier tube is coupled to the control grid of the 6L7 converter tube through the properly selected tuned R. F. transformer. The only exceptions to this procedure occur when the receiver is operating on the "Long Wave" "A" band or the ultra short wave "E" band, in which positions the R. F. tube is disconnected from the circuit and the antenna coupled directly to the 6L7 grid through the tuned antenna transformer.

The oscillator circuit, with the exception of the ultra short wave "E" band, employs a 6J7 tube in a conventional tuned grid, plate feedback circuit. In the ultra short wave "E" band, the common impedance between the grid and plate circuits provided by the secondary of L-13 in the cathode circuit of the 6K7 oscillator tube is utilized to provide oscillation. An auxiliary feedback circuit, composed of the primary, L-13, together with the capacitor, MC-38, is in the plate circuit of the oscillator tube on the "E" band. These elements resonate slightly below the low frequency end of the "E" band and tend to improve the oscillator excitation at this end of the band. To minimize capacity effects, the tuned "E" band grid coil, L-16, remains in the circuit at all times since its resistance is sufficiently low to permit this procedure. The grid coil of the broadcast "B" band oscillator returns to a point rather than to ground in order to provide plate voltage for the 6I7 AFC tube. The 580 kc. padding capacitor, C-27, serves to isolate this voltage from the oscillator tuning control network to provide proper balance of high and low notes at different volume control settings.

Electrical Power Output

Undistorted: 20 watts
Maximum: 37.5 watts

Loud-speaker—Electrodynamic

Cone Diameter: 15 in.
Cone Coil Impedance 10 ohms at 400 cycles

The 6I7 AFC tube is also located on the "Sentry Box" and is associated with the broadcast "B" band oscillator. A complete description of the operation of AFC is given in a later paragraph. The output of the converter is applied to the I. F. amplifier.

I. F. Amplifier

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformer and two 6K7 amplifier tubes. Each transformer has two tuned circuits which resonate at 465 kc. The third I. F. transformer is of special construction having a primary capacitor coupled to the midpoint of the secondary in order to provide the differential AFC voltage. The operation of this transformer is discussed in a special section on AFC.

Detector and AVC

The plates of the 6I6 twin diode are fed in push-pull by the secondary of the third I. F. transformer. Two diode loads consisting of R-24 and the series resistance of R-21, R-22, and R-23 are provided. The AFC voltage is developed across the sum of all these resistors, while the audio voltage appears across the sum of R-21, R-22, and R-23. A portion of the audio frequency thus provided is transferred to the A. F. system for amplification and reproduction. The direct current component of the rectified signal produces a voltage drop across the above three resistors. This voltage is employed to operate the 6K7 "Colorama" tuning tube. Switch S-11 permits the application of either full or partial voltage to the tube, thereby permitting control of the color indication in accordance with prevailing receiving conditions. A complete description of "Colorama" tuning is given in a later section. The D.C. voltage developed across R-21 and R-22 is utilized for automatic volume control action by employing the same to bias the R. F. amplifier, converter, and first I. F. amplifier tubes.

Initial control grid bias for these tubes is supplied by the delay bias diode under conditions of little or no signal. Under such conditions, this diode draws current through resistors R-21, R-22, and R-23, thereby maintaining the desired operating bias. When signal voltage above the level of the initial bias is applied, this diode ceases to draw current and the AVC diode takes over the biasing function.

The second I. F. tube receives no AVC and is self-biased. This minimizes the possibility of non-linear distortion on strong signals.

Noise Limiter

The other diode section of the auxiliary twin diode is employed as a transient noise-limiting device. This diode is so connected that its normal D. C. plate voltage has a value greater than the peak voltage of the audio signal applied through it to the manual volume control. Any transient signal of high voltage such as a static impulse will drive the plate negative, rendering the diode non-conducting and limiting the amount of transient voltage developed across the volume control.

Audio System

The manual volume control consists of a tapered potentiometer connected between the noise-limiting diode and the control grid of the 6G5 first audio amplifier. This control is tone-compensated by means of a resistance-capacitance network to provide proper balance of high and low notes at different volume control settings.

frequency 465 kc. higher than the incoming signal, is expected to be coupled to the injection grid of the 6L7 converter.

The 6I7 AFC tube is also located on the "Sentry Box" and is associated with the broadcast "B" band oscillator. A complete description of the operation of AFC is given in a later paragraph. The output of the converter is applied to the I. F. amplifier.

I. F. Amplifier

The intermediate frequency amplifier consists of a two-stage cascade section composed of three I. F. transformer and two 6K7 amplifier tubes. Each transformer has two tuned circuits which resonate at 465 kc. The third I. F. transformer is of special construction having a primary capacitor coupled to the midpoint of the secondary in order to provide the differential AFC voltage. The operation of this transformer is discussed in a special section on AFC.

Detector and AVC

The plates of the 6I6 twin diode are fed in push-pull by the secondary of the third I. F. transformer. Two diode loads consisting of R-24 and the series resistance of R-21, R-22, and R-23 are provided. The AFC voltage is developed across the sum of all these resistors, while the audio voltage appears across the sum of R-21, R-22, and R-23. A portion of the audio frequency thus provided is transferred to the A. F. system for amplification and reproduction. The direct current component of the rectified signal produces a voltage drop across the above three resistors. This voltage is employed to operate the 6K7 "Colorama" tuning tube. Switch S-11 permits the application of either full or partial voltage to the tube, thereby permitting control of the color indication in accordance with prevailing receiving conditions. A complete description of "Colorama" tuning is given in a later section. The D.C. voltage developed across R-21 and R-22 is utilized for automatic volume control action by employing the same to bias the R. F. amplifier, converter, and first I. F. amplifier tubes.

Initial control grid bias for these tubes is supplied by the delay bias diode under conditions of little or no signal. Under such conditions, this diode draws current through resistors R-21, R-22, and R-23, thereby maintaining the desired operating bias. When signal voltage above the level of the initial bias is applied, this diode ceases to draw current and the AVC diode takes over the biasing function.

The second I. F. tube receives no AVC and is self-biased. This minimizes the possibility of non-linear distortion on strong signals.

Noise Limiter

The other diode section of the auxiliary twin diode is employed as a transient noise-limiting device. This diode is so connected that its normal D. C. plate voltage has a value greater than the peak voltage of the audio signal applied through it to the manual volume control. Any transient signal of high voltage such as a static impulse will drive the plate negative, rendering the diode non-conducting and limiting the amount of transient voltage developed across the volume control.

Audio System

The manual volume control consists of a tapered potentiometer connected between the noise-limiting diode and the control grid of the 6G5 first audio amplifier. This control is tone-compensated by means of a resistance-capacitance network to provide proper balance of high and low notes at different volume control settings.

frequency 465 kc. higher than the incoming signal, is expected to be coupled to the injection grid of the 6L7 converter.

MODEL E-155

Alignment

GENERAL ELECTRIC CO.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal to the receiver from the test oscillator at the alignment frequency and inserting a "Tuning Wand" into the coil involved. The tuning wand consists of a rod of insulating material having a ring of non-magnetic metal attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the metal ring end into the center of the R. F. coil, the inductance of this coil is lowered, increasing its resonant frequency. Inserting the iron filled end into the coil raises its inductance, lowering its resonant frequency. If the R. F. circuits are in exact alignment, inserting either end of the tuning wand into the coil will result in a decrease in output. When an increase of signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase of signal is obtained with the metal ring, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand		
Wand	Signal	Trimmer Adjustment Required
Metal Ring	Decrease	None
Iron Filings	Increase	
Changes Indicated by Wand (Cont.)		
Wand	Signal	Trimmer Adjustment Required
Metal Ring	Increase	Decrease capacity
Iron Filings	Decrease	
Metal Ring	Decrease	Increase capacity
Iron Filings	Increase	

ALIGNMENT FREQUENCIES

I. F. Band "A" 465 kc. 145 kc. Band "B" 580 kc. Band "C" 5220 kc. Band "D" 18,000 kc. Wave Trap 465 kc. 1800 kc.

In order to align these receivers properly it is necessary to have available:

1. A modulated test oscillator capable of producing the above alignment frequencies.
2. An output indicator, such as a high resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of a fiber shaft screw-driver.
4. A tuning wand.

To realize the full advantage of the performance built into these receivers at the factory, circuit alignment using cathode ray oscilloscope equipment is much to be preferred. The oscilloscope method is particularly advantageous in aligning the I. F. tuned circuits.

The location of all alignment trimmer capacitors, as well as socket voltages, is shown in Fig. 4.

1. Visual Alignment of I. F.

For visual alignment it is necessary to vary the frequency of an unmodulated test oscillator signal over a range extending on both sides of the peak frequency. This variation must take place in synchronism with the horizontal traverse of the cathode ray beam on its screen. The frequency modulator must, therefore, provide means for synchronizing the periodic test frequency variation with the cathode ray horizontal deflection circuit. The test oscillator may advantageously have facilities for audio frequency amplitude modulation of a fixed radio frequency test signal, as well as for frequency modulation, but audio modulation is not required for visual I. F. alignment.

Instead of an output meter across the speaker voice coil, the vertical plates of the cathode ray tube are connected across the load resistor of the diode rectifier. With the frequency modulator in operation in conjunction with the test oscillator, the resonance curve of the circuit under test will be then shown on the screen.

Set the tuning dial indicator at the low end of the broadcast band at some point where no signal is received, since an extraneous signal might interfere with the aligning process. The volume control should be in an "off" or nearly off position. Apply a frequency modulated signal to the grid of the 1st I. F. amplifier tube through a .05 Mfd. (RC-072) capacitor, leaving the grid cap in place. Connect the vertical

plates of the oscilloscope between ground and the junction point between R-23 and R-24, and with the AFC switch in the "off" position proceed to align the primary and secondary of the 2nd I. F. and the AFC I. F. transformers.

The object should be to make the two curves coincide with each other at the top and throughout their length with the maximum amplitude obtainable. This will require that all four I. F. trimmers be adjusted in the usual manner *excepting the AFC secondary (hexagonal nut) trimmer which must be adjusted for minimum amplitude* before the curves will coincide properly. Fig. 5 gives the appearance of the curve when the alignment adjustments have been completed satisfactorily thus far. Apply the same frequency modulated input to the grid of the converter (6L7) tube through a .05 Mfd. capacitor as before. Adjust the primary and secondary of the 1st I. F. transformer until the curves coincide as before and have the appearance of Fig. 5.

A further adjustment of the AFC secondary (hexagonal nut) trimmer is necessary in order to complete the I. F. alignment satisfactorily. Apply the same signal to the grid of the second I. F. amplifier tube. Unsolder the ground end of TC-53 and connect the vertical deflecting plates of the oscilloscope between ground and the 6H6 cathode prong K1 (Fig. 3). Since the cathode prong is inaccessible, this connection can be made at the AFC switch center contact.

Carefully adjust the AFC secondary trimmer until a curve is obtained which is similar to that shown in Fig. 6. Correct adjustment is made when the two sides of the curve are symmetrical and intersect exactly at the horizontal axis. No adjustment of the other I. F. trimmer should be made at this time.

If a metal aligning tool is used, the curve will change when the tool is withdrawn. Therefore, it is advisable to use a fiber hex-headed wrench for this aligning adjustment. At any rate, the final curve should be as shown with aligning tool removed.

2. I. F. Wave Trap Alignment

Leave the band switch at Band "B" and tune receiver to about 1000 kc.

With the test oscillator set at 465 kc. apply this signal to the antenna terminal through a dummy antenna consisting of a 400 ohm resistor and 250 mmfd. capacitor in series. With the 465 kc. signal applied to the antenna terminal, adjust the I. F. Wave Trap Trimmer for *minimum* output indication.

3. R. F. Alignment

First check the position of the dial pointer by rotating the tuning condenser to maximum capacity position, i.e., plates fully meshed. At this position, the pointer should coincide with the end mark at the left-hand end of the scale. If it does not, it may be set by loosening the pointer set screw and setting the pointer to its correct position. During R.F. alignment the AFC switch *must* be set in its "off" (counter-clockwise) position.

Band "A" (140-420 Kc.)

Set the test oscillator for operation at 400 kc. and connect its output to the antenna terminal of the receiver through the dummy antenna described under I. F. Wave Trap Alignment. Tune the receiver until the pointer is at 400 on the scale. Set the tone control for minimum high response and reduce the volume control setting so as to avoid excessive noise response. Adjust the Band "A" oscillator and antenna trimmers respectively (see Fig. 4) to give maximum deflection on the output meter. Maintain the test oscillator at the lowest level which will give an easily readable output indication.

Now set the test oscillator at 145 kc. and tune the receiver to resonance with this signal. Adjust the 145 kc. padding capacitor rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned in this manner. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 400 kc. and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "A" oscillator and antenna trimmers for maximum deflection on the tuning meter.

Band "B" (340-1620 Kc.)

Set the test oscillator for operation at 1500 kc. and tune the receiver until the pointer is at 1500 on the scale. Adjust the Band "B" oscillator, R. F., and antenna trimmers respectively (see Fig. 4) to give maximum deflection on the output meter. Maintain the test oscillator output at the lowest level which

will give an easily readable output indication.

Now set the test oscillator at 580 kc. and tune the receiver to resonance with this signal. Adjust the 580 kc. padding capacitor, rocking the tuning condenser back and forth through resonance as the padding capacitor is adjusted and note the deflection of the tuning meter each time the receiver is tuned in this manner. Leave the padding capacitor at the setting which gives greatest deflection.

Retune the receiver to 1500 kc. and set the test oscillator for this frequency. Check the alignment by again adjusting the Band "B" oscillator, R. F. and antenna trimmers for maximum deflection on the tuning meter.

Band "C" (1610-5580 Kc.)

With the test oscillator connected to the receiver as above, tune the receiver until the pointer is at 5220 on the "C" band scale. Set the test oscillator for operation on this frequency and, with the volume and tone controls set as above, adjust the Band "C" oscillator, R. F. and antenna trimmers, respectively (see Fig. 4) to give maximum deflection on the output meter.

Band "D" (5-18.1 Mc.)

Turn the band switch to Band "D." Set the test oscillator at 18,000 kc. (18.0 Mc.) and tune the receiver until the pointer coincides with the 18.0 mark. Adjust the Band "D" oscillator trimmer, C-35, to give maximum output indication. It will probably be found that there will be two settings of the oscillator trimmer that will give an output response. The lower capacity setting of the trimmer is the one that should be used. To be sure that correct adjustment has been obtained, tune for the image signal at 17.07 Mc. with the test oscillator at 18.0 Mc. It may be necessary to increase the test oscillator output to obtain response at this point.

Retune the receiver to 18.0 Mc. and adjust Band "D" antenna and R. F. trimmers, respectively (see Fig. 4) for maximum output indication. When adjusting the R. F. trimmer rock the tuning condenser back and forth through resonance as in the 580 kc. padding capacitor adjustment. Alignment of the receiver is now complete as no adjustments are provided on band "E."

4. I. F. Alignment with Output Meter

Although the use of the cathode-ray oscilloscope for alignment purposes is to be preferred, it is possible to make the I. F. trimmer adjustments with reasonable accuracy using a 465 kc. signal generator and output meter.

Place a modulated signal of 465 kc. on the grid of the last I. F. (6K7) tube with the volume control set at maximum and the AFC switch turned off. Place a low range A.C. voltmeter or other output indicator across the voice coil of the loud-speaker. Adjust the output of the signal generator so that an indication of not more than two or three volts is obtained on the output meter.

Adjust and readjust the primary trimmer for maximum output and the secondary for *minimum* output. This latter adjustment will be very broad. Apply the signal input to the grid of the 1st I. F. (6K7) tube and adjust both primary and secondary trimmers for maximum output indication in the same manner as before.

It is now necessary to make a fine adjustment of the secondary trimmer of the last I. F. (AFC) transformer, which is as follows: without changing the frequency of the signal generator, place the input lead on the rubber insulation of the converter (6L7) grid lead. This will provide a small signal input through the capacity between the leads. Increase the attenuator setting if necessary to make the output audible. If the signal generator is provided with a means of removing the modulation, this should be done. However, the adjustment may be carried out satisfactorily even with a modulated generator signal.

Now tune in any broadcast signal in the usual manner and tune carefully for zero beat between this carrier and the 465 kc. signal generator. It may be necessary to use a short antenna or to remove it entirely if the station is a strong local. Throw the AFC on and adjust the last I. F. secondary (AFC) trimmer to give zero beat. This adjustment is very critical and must be made with great care. When the adjustment is properly made, there will be no appreciable change from zero beat as the AFC switch is thrown off and on. This completes the alignment of the I. F. and AFC circuits.

The alignment of the oscillator and R. F. circuits may be carried out in the usual manner. The AFC switch must remain in the off position.

GENERAL ELECTRIC CO.

MODEL E-155
Dial Data**ADJUSTMENT OF DIAL MECHANISM**

The dial mechanism (Fig. 7) is rigidly mounted to the "Sentry Box" by means of two brackets and four screws. The dial pointer is operated by means of an "Automatic Vernier" reduction drive unit. Motion imparted to the gang condenser rotor is transmitted through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail below the dial scale.

To Replace Cables

To replace cord or cable for the pointer or drive, the chassis should be removed from the cabinet and the dial mask (No. 14) removed from the dial scale box (No. 5). The black drive cord (No. 25) should run between the drum (No. 6) on the condenser and the drive pulley without crossing. Both the black cord (No. 25) and the bronze cable (No. 24) fasten on the same hook in the drum (No. 6) which is in front of the single lance on the outside diameter. The springs (21) and (22) are fastened on the ends of the cables after passing through the lances which are close together on the condenser drive drum. The light spring (No. 21) is on the bronze cable (No. 24) and the special spring loop hooks into the hole in the drum next to the hook for the spring on the black cord (No. 25). The solid end of the cord or cable should be fastened first to the drum, the line should be then strung around the pulleys and drum and lastly, the spring should be stretched into place.

To Adjust Pointer for Calibration

The pointer (No. 27) is adjustable by removing the escutcheon plate and also the dial mask (No. 14) which is held by four screws. The screw in the center of the pointer (No. 27) can then be loosened and the pointer adjusted as needed.

To Replace Scale

The scale (No. 3) can be removed by taking off the escutcheon and the dial mask (No. 14) as for the adjustment of the pointer. The pointer (No. 27) is moved to the left-hand end, the scale is then pushed to the left and the right-hand end is pulled out with the aid of a small screwdriver or a similar tool. When replacing the scale (No. 3) it is advisable to remove the cord (No. 23). The spring (No. 9) is put on the dial shaft and the shaft then inserted into the housing. The scale (No. 3) with the right-hand cap (No. 8) attached is then inserted into the left-hand cap (No. 7) which is held in position by pulling on the shaft on the outside of the housing. After the scale (No. 3) is inserted it should be rotated from one to two turns against the action of the torsion spring (No. 9). The cord (No. 23) is then replaced in the lance provided for it. It is advisable to have the band switch rotated so that the greatest length of cord possible is unwound from the lower pulley (No. 4) on the band switch shaft. It is best that the chassis be removed for the replacement of a scale.

It is important when replacing the chassis in the cabinet that the rubber grommets should be put in the chassis and not on the wood pins.

To Adjust Rotation of the Scale

With the chassis out of the cabinet the scale (No. 3) can be adjusted to track properly on the various bands by loosening the set screw and rotating pulley (No. 4) on the band switch shaft.

To Change the Dial Lamps

Make certain that the copper-plated hex head shipping screw which secures the dial lamp bracket during shipment has been removed before attempting to remove the dial lamp bracket (No. 17). Lift the lamp bracket from the tabs under which it is clipped. Care should be taken that the lamp leads do not put an undue strain upon the drive cable. With the lamp bracket laid back horizontally the lamps may be replaced. When the lamp bracket is reinserted care should be exercised to avoid having the lamp leads foul the gang mechanism.

Automatic Frequency Control

Automatic frequency control (AFC) is a device for automatically controlling the oscillator frequency in such a way that, although the receiver is not exactly tuned to the signal being received, the correct intermediate frequency will still be produced. This control of the oscillator frequency is secured by means of the 6J7 AFC tube, so connected to the oscillator that it draws a lagging current from the tank circuit and thus gives the effect of a shunt inductance. Variation of the D.C. grid bias on the 6J7 control tube will affect the mutual conductance of the tube, thereby changing the amount of lagging current drawn from the oscillator tank with a consequent effect of variation of the amount of shunt inductance connected across the oscillator coil. This alters the total inductance in the oscillator tuned circuit and changes its resonant frequency.

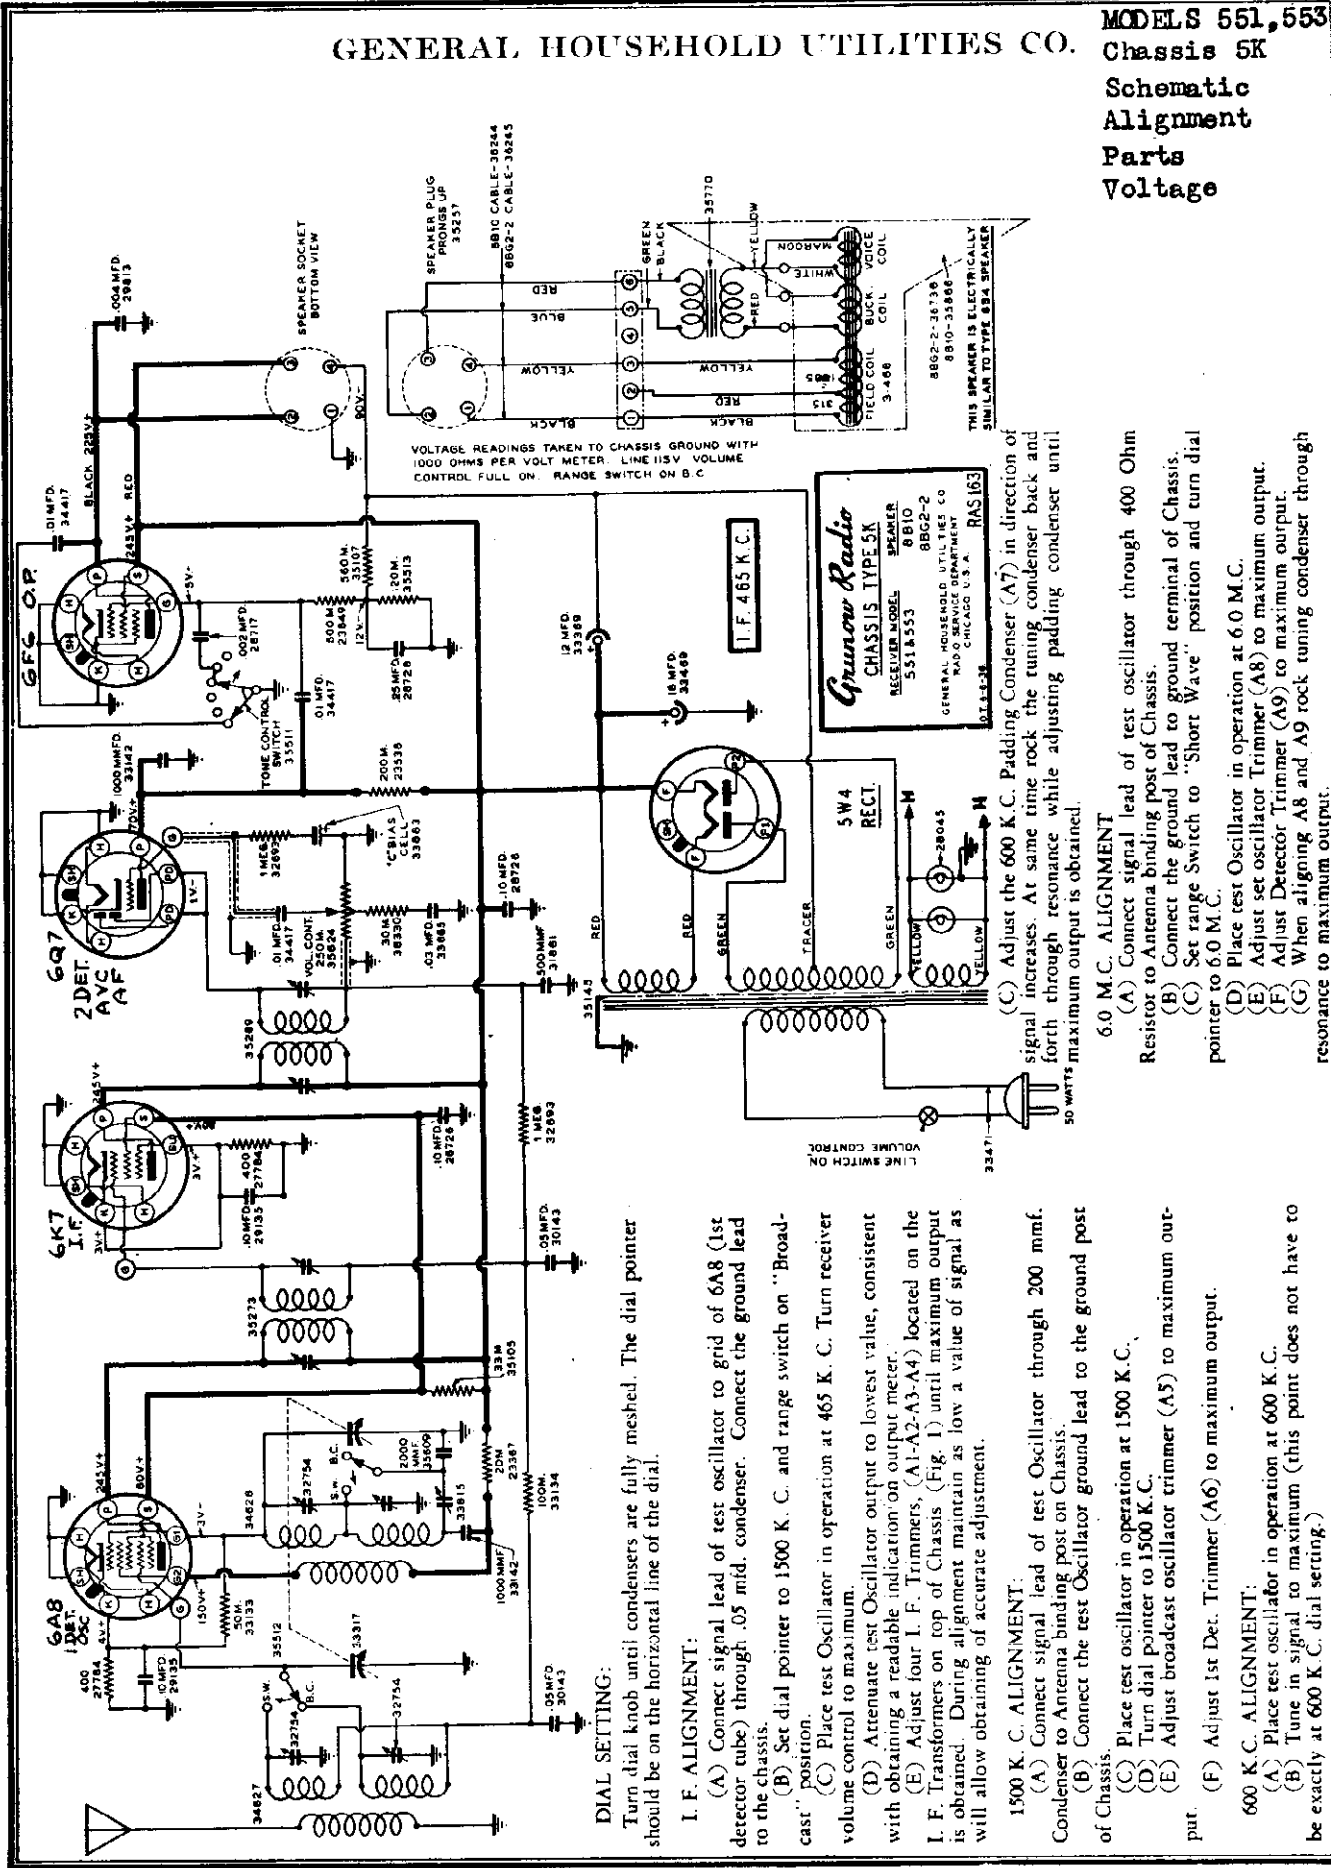

Grid bias for the 6J7 control tube, which will vary in accordance with the amount of detuning of the receiver, is obtained from the 6H6 diode rectifier operating in conjunction with its special I. F. transformer. This control voltage is the difference between the drop across resistor R-24, the load resistance for one diode section of the 6H6 diode rectifier, and the drop across resistors R-21, R-22 and R-23, which constitute the load resistance for the other diode section. When the receiver is correctly tuned to the incoming signal, the intermediate frequency produced will be 465 kc. which is the resonant frequency of the tuned circuit feeding the 6H6 diode rectifier. Under this condition each diode plate receives equal signal voltage and the D.C. voltage drops across the load resistors will be equal, giving no change in grid bias on the 6J7 control tube. If the receiver is so tuned that the intermediate frequency produced is above 465 kc., the signal voltage applied to diode plate No. 6 will exceed that applied to diode plate No. 7. In this case, the D.C. voltage drop across load resistance R-21, R-22 and R-23 will be larger than that across load resistor R-24 and a resultant voltage will be produced which will increase the 6J7 AFC tube grid bias, lowering the mutual conductance of the tube and causing it to draw less lagging current from the oscillator tank. This is the same effect as would be produced by increasing the amount of shunt inductance across the oscillator coil and the oscillator frequency is thereby lowered by the amount necessary to compensate for the detuning. The opposite takes place when the receiver is tuned so as to produce an intermediate frequency below 465 kc. Diode plate No. 6 then receives more signal voltage than diode plate No. 7 and the resultant voltage developed across the load resistance is such as to decrease the grid bias on the 6J7 AFC tube. This causes a larger current to be drawn from the oscillator tank circuit, which in effect is the same as a decrease in shunt inductance with its consequent increase in oscillator frequency to overcome the detuning.

DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

I. F. ALIGNMENT:

- (A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .05 mfd. condenser. Connect the ground lead to the chassis.
- (B) Set dial pointer to 1500 K. C. and range switch on "Broadcast" position.
- (C) Place test Oscillator in operation at 465 K. C. Turn receiver volume control to maximum.
- (D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.
- (E) Adjust four I. F. Trimmers, (A1-A2-A3-A4) located on the I. F. Transformers on top of Chassis (Fig. 1) until maximum output is obtained. During alignment maintain as low a value of signal as will allow obtaining of accurate adjustment.

1500 K. C. ALIGNMENT:

- (A) Connect signal lead of test Oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.
- (B) Connect the test Oscillator ground lead to the ground post of Chassis.
- (C) Place test oscillator in operation at 1500 K. C.
- (D) Turn dial pointer to 1500 K. C.
- (E) Adjust broadcast oscillator trimmer (A5) to maximum output.
- (F) Adjust 1st Det. Trimmer (A6) to maximum output.

600 K. C. ALIGNMENT:

- (A) Place test oscillator in operation at 600 K. C.
- (B) Tune in signal to maximum (this point does not have to be exactly at 600 K. C. dial setting.)

(C) Adjust the 600 K. C. Padding Condenser (A7) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until 50 WATTS maximum output is obtained.

6.0 M.C. ALIGNMENT

- (A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.
- (B) Connect the ground lead to ground terminal of Chassis.
- (C) Set range Switch to "Short Wave" position and turn dial pointer to 6.0 M.C.
- (D) Place test Oscillator in operation at 6.0 M.C.
- (E) Adjust set oscillator Trimmer (A8) to maximum output.
- (F) Adjust Detector Trimmer (A9) to maximum output.
- (G) When aligning A8 and A9 rock tuning condenser through resonance to maximum output.

DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

I. F. ALIGNMENT:

- (A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .05 mfd. condenser. Connect the ground lead to the chassis.
- (B) Set dial pointer to 1500 K. C. and range switch on "A" position.
- (C) Place test Oscillator in operation at 465 K. C. Turn receiver volume control to maximum.
- (D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.
- (E) Adjust four I.F. Trimmers, (A1, A2, A3, A4) located on the I. F. Transformers on top of Chassis (Fig. 1) until maximum output is obtained. During alignment maintain as low a value of signal a will allow obtaining of accurate adjustment.

1500 K. C. ALIGNMENT:

- (A) Connect signal lead of test Oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.
- (B) Connect the test Oscillator ground lead to the ground post of Chassis.
- (C) Place test oscillator in operation at 1500 K. C.
- (D) Turn dial pointer to 1500 K. C.
- (E) Adjust broadcast oscillator trimmer (A5) to maximum output.

- (F) Adjust 1st Detector Trimmer (A6) to maximum output.
- (G) Adjust Antenna Trimmer (A7) to maximum output.

600 K. C. ALIGNMENT:

- (A) Place test oscillator in operation at 600 K. C.
- (B) Tune in signal to maximum (this point does not have to be exactly at 600 K. C. dial setting).
- (C) Adjust the 600 K. C. Padding Condenser (A8) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until Resistor to Antenna binding post of Chassis.

- (B) Connect the ground lead to ground terminal of Chassis.
- (C) Set Range Switch to "C" position and turn dial pointer to 18 M. C.
- (D) Place test Oscillator in operation at 18 M. C.
- (E) Adjust set oscillator Trimmer (A11) to maximum output.
- (F) Adjust Detector Trimmer (A12) to maximum output.
- (G) On the 18 M. C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point that is the setting giving most capacity or the point at which the trimmer screw is farthest in.

maximum output is obtained.
 5000 K. C. ALIGNMENT:
 (A) Set Range Switch to "B" position.
 (B) Place test Oscillators in operation at 5000 K. C.
 (C) Turn Dial Pointer to 5000 K. C.
 (D) Adjust Set Oscillator Trimmer (A9) to maximum output.
 (E) Adjust Detector Trimmer (A10) to maximum output.
 18 M. C. ALIGNMENT:
 (A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.

THIS SUPERSEDES MANUAL OF PREVIOUS DATE.

SERVICE NOTES

Chassis Type S-S

Receiver Model 566

Speaker Type BBG1-1—BBG1-2

The following characteristics apply to the GRUNOW Radio—Chassis 5S:

This model is a 5 Tube Super-Heterodyne Dual Wave (540 to 1725 K.C. and 1725 to 4000 K.C.) Receiver, using 1-6A7 tube as 1st Detector and Oscillator, 1-6D6 tube as

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man

an I. F. Amplifier, 1-76 tube as 2nd Detector and Audio Amplifier. The 41 output tube is a power amplified pentode and is capable of producing large power output with relatively small signal input. The rectifier tube is an 86, the output of which is well filtered through the action of the speaker field and the two 8 mfd. electrolytic condensers.

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 3) are shown from view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the volume control "full on" and the range switch in position "A" using a 1000 ohms per volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was located and connected. This applies particularly to ground points. All parts replacements in the R. F. end of the circuit must be exact duplicates of the originals, especially so in the case of coils, R. F. by-pass or coupling condensers. Any repairs in the R. F. circuit will make a complete realignment of the tuned circuit necessary.

BIAS CELL

This Chassis uses a "C" bias cell unit in the control grid

CIRCUIT ALIGNMENT PROCEDURE

1. HEATING
(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion and contraction of the chassis parts.
(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

2. DIAL CALIBRATION

Turn the condenser until the pointer is fully marked, set the pointer (Hour Hand) to 9 and 3 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the first point on 12.

3. SIGNAL GENERATOR ADJUSTMENT

During the entire alignment procedure, the signal input from the generator to the receiver must be continually attenuated at the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A. V. C. Circuit will remain at the most sensitive points.

4. I. F. ALIGNMENT

(A) Set the generator to 465 K.C. and connect the output lead of the 41 tube through the .05 Mfd. condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.
(B) Set the receiver dial pointer to 600 K.C. the range switch to position "A" and turn the volume control full on.
(C) Connect the output meter across the two primary terminals on the output transformer.
(D) Adjust the I. F. Trimmers A1, A2, A3, and A4 to maximum output.

divisions or bands covering from 530 K.C. to 1750 K.C. on the "A" or Broadcast Band, 1750 K.C. to 5.5 M.C. on the "B" or Police Amateur Band and 5.5 M.C. to 18.2 M.C. on the "C" or Foreign Broadcast Band.

SERVICE DATA

of the 6Q7 tube. This type bias cell has an exceedingly long life but occasionally may have to be replaced. When replacing the cell note that the carbon or (+) side is connected to the ground side of all terminal clips. To check the bias cell a new cell or a 1 1/2 volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating.

CIRCUIT ALIGNMENT EQUIPMENT

Do not attempt to align the 9Q Chassis without the equipment specified below:

1. Signal Generator—A modulated oscillator capable of delivering from 465 K.C. to 18.2 M.C.
2. Alignment Tool—A non-metallic screw driver.
3. Dialing Amplifier—A 200 Mmf. Condenser (I. F. Alignment); 200 Mmf. Coupling Condenser (I. F. Alignment); 400 Ohm Carbon Resistor (Short Wave Alignment)
4. Output Meter—A meter of sufficient sensitivity to give a good deflection at very low signal input.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

CIRCUIT ALIGNMENT PROCEDURE

3. 1500 K.C. ALIGNMENT
(A) Set the generator to 1500 K.C. and connect the output to the antenna post on the chassis through the 200 Mmf. condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.
(B) Set the receiver dial pointer to 1500 K.C.
(C) Adjust the trimmers (A1) Oscillator, (A6) Detector and (A7) Antenna to maximum output.

6. 600 K.C. ALIGNMENT
(A) Set generator to 600 K.C.
(B) Set receiver dial pointer to 600 K.C.
(C) Turn trimmer (A6) in direction of signal increase and at the same time rock tuning condenser slowly back and forth through resonance until the exact resonant point on both is obtained.

7. 5 M.C. ALIGNMENT

(A) Set generator to 5 M.C.
(B) Set receiver range switch to position "B" and dial pointer to 5 M.C.
(C) Adjust trimmer (A9) Oscillator and (A10) Antenna to maximum output.

8. 18 M.C. ALIGNMENT

(A) Set generator to 18 M.C. and connect the output to the chassis Antenna post through the 400 Ohm condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.
(B) Set the receiver range switch to position "C" and the dial pointer to 18 M.C.
(C) Screw the Oscillator trimmer (A11) down tight and slowly back until signal is heard, then rock the tuning condenser back and forth through resonance until exact resonant point is determined.
(D) Adjust Antenna trimmer (A12) to maximum output.
(E) Readjust Oscillator trimmer (A11) to maximum output.

OCTOBER, 1936

SERVICE DATA

Chassis Type 5Q

Receiver Model 573

Grunow Radio

The following characteristics apply to the GRUNOW Radio—Chassis 5S:

This model is a 5 Tube Super-Heterodyne Dual Wave (540 to 1725 K.C. and 1725 to 4000 K.C.) Receiver, using 1-6A7 tube as 1st Detector and Oscillator, 1-6D6 tube as

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man

an I. F. Amplifier, 1-76 tube as 2nd Detector and Audio Amplifier. The 41 output tube is a power amplified pentode and is capable of producing large power output with relatively small signal input. The rectifier tube is an 86, the output of which is well filtered through the action of the speaker field and the two 8 mfd. electrolytic condensers.

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 3) are shown from view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the volume control "full on" and the range switch in position "A" using a 1000 ohms per volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was located and connected. This applies particularly to ground points. All parts replacements in the R. F. end of the circuit must be exact duplicates of the originals, especially so in the case of coils, R. F. by-pass or coupling condensers. Any repairs in the R. F. circuit will make a complete realignment of the tuned circuit necessary.

BIAS CELL

This Chassis uses a "C" bias cell unit in the control grid

CIRCUIT ALIGNMENT PROCEDURE

1. HEATING
(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion and contraction of the chassis parts.
(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

2. DIAL CALIBRATION

Turn the condenser until the pointer is fully marked, set the pointer (Hour Hand) to 9 and 3 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the first point on 12.

3. SIGNAL GENERATOR ADJUSTMENT

During the entire alignment procedure, the signal input from the generator to the receiver must be continually attenuated at the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A. V. C. Circuit will remain at the most sensitive points.

4. I. F. ALIGNMENT

(A) Set the generator to 465 K.C. and connect the output lead of the 41 tube through the .05 Mfd. condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.
(B) Set the receiver dial pointer to 600 K.C. the range switch to position "A" and turn the volume control full on.
(C) Connect the output meter across the two primary terminals on the output transformer.
(D) Adjust the I. F. Trimmers A1, A2, A3, and A4 to maximum output.

1. EQUIPMENT

A—Test Oscillator.
A modulated oscillator capable of producing signals at 465 K. C., 1500 K. C., 1000 K. C., 600 K. C. and 3500 K. C. is necessary for alignment of the 5S Grunow Receiver.
B—Output Meter.
This may be any of the standard output meters on the market, but should be sufficiently sensitive to provide a good deflection at low signal strength.

C—Coupling Meter.

Coupling condensers of .05 Mfd. and 200 Mmf. should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. DIAL SETTING.

Turn dial pointer until condensers are fully marked. The dial pointer should be on the horizontal line of the dial chart.

3. I. F. ALIGNMENT.

A—Connect signal lead of oscillator through .05 Mfd. condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.

B—Place oscillator in operation at 465 K. C. and turn receiver Volume Control to maximum (Volume Control should remain at maximum during the entire alignment procedure and signal should be attenuated at oscillator to lowest value consistent with obtaining a readable indication on output meter).

GRUNOW REMOTE CONTROL UNIT KITS
For Use on Grunow Auto Radio Models 614-618 and 625

NOVEMBER, 1938
SERVICE DATA

Auto Radio Models 614 - 618 - 625

GENERAL

Model 614 is a single unit remote control superheterodyne receiver using the following tubes: 6K7-G R.F. Amplifier, 6A8-G 1st Det. and Oscillator, 6K7-G L.F. Amplifier, 6Q7-G 2nd Det. A.V.C. and Audio Amplifier, 6F6-G Power Output, 6X5-G Rectifier; Vibrator is a non-synchronous plug-in type.

Model 618 is a double unit, remote control superheterodyne receiver using the same tubes as Model 614, with a separate speaker, either a dash type (8D1) or an overhead speaker. The overhead speaker can also be installed on the back of the front seat.

Model 625 is a double unit, remote control superheterodyne receiver with provision made for the addition of a second speaker (overhead type). This receiver uses the following tubes: 6K7-G R.F. Amp., 6A4-G 1st Det. and Osc., 6K7-G L.F. Amp., 6N7-G 2nd Det., A.V.C. and Audio Amp., 6C5-G Audio Driver, 6AG Push-Pull Power Output. Since this receiver uses a synchronous vibrator, make certain when installing, that polarity of receiver agrees with polarity of car. If it is necessary to reverse polarity, this may be done at the top of the vibrator transformer without removing chassis from its case (see Fig. 2).

CIRCUIT ALIGNMENT

- If alignment is found necessary, make all adjustments with the chassis in its case and use a calibrated test oscillator and an output meter. Allow chassis and test oscillator to warm up before making any adjustments.
1. PEAKING L.F. STAGES AT 262 K.C.
 - (a) Connect the ground lead of the test-oscillator to the chassis frame. Connect a .10 mfd. condenser in series with the signal lead and connect this lead to the grid cap of the 6A7 tube (leave grid clip in place.)
 - (b) Set the test-oscillator to exactly 262 K.C.
 - (c) Turn the volume control of the receiver full on.
 - (d) Adjust the L.F. trimmers A1, A2, A3, A4. In order to insure accurate setting of these trimmers, the adjustments should be repeated using the lowest oscillator output, that will give a reasonable deflection of the output meter pointer. Make all adjustments for maximum output.
 2. ALIGNING GANG CONDENSER AT 1560 AND 1460 K.C.
 - (a) Connect the signal lead of the test-oscillator to the antenna connection of the chassis, substituting a 250 mmfd. condenser for the .10 mfd. condenser. Turn the rotor plates of the gang condenser until they are completely out of mesh.
 3. ALIGNING AT 600 K.C.
 - (a) Change the test-oscillator to 600 K.C.
 - (b) Turn the condenser rotor plates until the 600 K.C. signal is tuned in at maximum.
 - (c) Adjust the antenna padding condenser A8 while rocking the condenser gang back and forth slightly until no further improvement in output can be obtained.
 - (d) It is well to return to 1400 K.C. and recheck at this frequency, then recheck 600 K.C. while rocking gang condenser.
- Caution*—On all of the above operations always use the lowest oscillator output that will give a reasonable deflection of the output meter in order to prevent the A.V.C. from leveling out the output as adjustments are made.

Alignment

GENERAL HOUSEHOLD UTILITIES CO.

ALIGNMENT PROCEDURE

This chassis utilizes a "C" bias cell in the control grid of the 6Q7 tube. To check the cell, a new one or a 1.5 volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating. When replacing the cell note that the carbon (+) side is connected to the ground side of the terminal clip.

ALIGNING I.F. STAGES AT 465 KC.

Connect the ground lead of the signal generator to the chassis sub-panel. Connect an .05 mfd. cond. in series with the signal lead and connect it to the grid clip of the 6A8 tube. Set sig. gen. at 465 KC and turn receiver volume full-on. Adjust I.F. trimmers A1, A2, A3 & A4 to maximum output. To insure accurate adjustment repeat the operation, using the lowest sig. gen. output that will give a readable deflection of the output meter.

DIAL CALIBRATION

With the condenser fully meshed the dial pointer should coincide with the horizontal line on the dial chart.

1400 KC. ALIGNMENT

Turn range switch knob to left. Connect a 200 mmf. condenser in series with the signal lead and connect the lead to the antenna wire. Set sig. gen. to 1400 KC. Turn condenser to 140 (1400) dial reading and adjust trimmers A5, A6 & A7 to maximum output.

600 KC. ALIGNMENT

Change sig. gen. to 600 KC. and tune in signal to maximum. (This point may not coincide exactly with 600 KC. dial reading). Adjust the 600 Kc. padder A8 while rocking the condenser gang slowly in direction of signal increase until no further improvement in output can be obtained.

SHORT WAVE ALIGNMENT

Turn range switch knob to right. Remove 200 mmf. condenser from signal lead and connect a 400 ohm carbon resistor in its place. Change signal gen. to 6 mc. dial reading, adjust trimmers A9, A10 & A11 to maximum output.

Note:- On all of the above operations use the lowest sig. gen. output that will give a readable deflection of the output meter in order to prevent the A. V. C. from levelling the output as adjustments are made.

SERVICE DATA

Chassis Type 7M
Receiver Model 725, 731, 725, 735
Speaker Type 1210A3-1210A4

The Grunow Chassis 7M is a seven tube, three band heterodyne receiver using 1-6E5 Beacon Eye tuning indicator, 1-6A8 1st Detector and Oscillator, 1-6K7 1st I. F. Amplifier, 1-6K2 2nd I. F. Amplifier, 1-6Q2 2nd Detector, A. V. C. and Audio Amplifier, 1-6F6 Power Output, and 1-5W4 Rectifier. The tuning range is divided into three divisions or bands covering from 550 K.C. to 1750 K.C. on "A," Broadcast Band, 1750 K.C. to 5.5 M.C. on the "B," Police Amateur Band, and 5.5 M.C. to 18.2 M.C. on the "C," Foreign Broadcast Band.

SERVICE DATA

CONTINUITY AND VOLTAGE
Tube sockets on the schematic diagram (Fig. 3) are shown both in their actual position in the chassis and in their correct position in the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the voltmeter control "full on" and the range switch in position "A" using a 1000 ohm per volt meter.

REPAIRS
When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was located and connected. This applies particularly to ground points. All parts replacements in the R. F. circuit must be exact duplicates of the originals, especially so in the case of coils, R. F. by-pass or coupling condensers. Any repairs in the R. F. circuit will make a complete re-alignment of the tuned circuit necessary.

BIAS CELL
This chassis uses a "C" bias cell unit in the control grid of the 6Q2 tube. This type bias cell has an exceedingly long life, but occasionally may have to be replaced. When replacing the cell note that the carbon or (+) side is connected to the ground side of all terminal clips. To check the bias cell a new cell or a 1 1/2 volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating.

CIRCUIT ALIGNMENT EQUIPMENT
Do not attempt to align the 6M Chassis without the equipment specified below:
1. Signal Generator—A modulated oscillator capable of delivering signals from 465 K.C. to 18.2 M.C.
2. Alignment Tool—A non-metallic screw driver.
3. Dummy Antenna—.05 Mfd. Condenser (I. F. Alignment); 200 Mmf. Condenser (Broadcast Alignment); 400 Ohm Carbon Resistor (Short Wave Alignment).
4. Output Meter—A meter of sufficient sensitivity to give a good deflection at very low signal input.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

CIRCUIT ALIGNMENT PROCEDURE

- 3. 1500 K.C. ALIGNMENT
(A) Set the generator to 1500 K.C. and connect the output to the antenna post on the chassis through the 200 Mmf. dummy.
(B) Set the receiver dial pointer to 1500 K.C.
(C) Adjust the trimmers (A7) Oscillator, (A8) Detector and (A9) Antenna to maximum output.
6. 600 K.C. ALIGNMENT
(A) Set generator to 600 K.C.
(B) Set receiver dial pointer to 600 K.C.
(C) Turn trimmer (A10) in direction of signal increase and at the same time rock tuning condenser slowly back and forth through resonance until the exact resonant point on both is obtained.

- 7. 5 M.C. ALIGNMENT
(A) Set generator to 5 M.C.
(B) Set receiver range switch to position "B" and dial pointer to 5 M.C.
(C) Adjust trimmer (A11) Oscillator and (A12) Antenna to maximum output.
8. 18 M.C. ALIGNMENT
(A) Set generator to 18 M.C. and connect the output to the chassis Antenna post through the 400 Ohm dummy.
(B) Set the receiver range switch to position "C" and the dial pointer to 18 M.C.
(C) Screw the Oscillator trimmer (A13) down tight and back off until signal is heard, then rock the tuning condenser slowly back and forth through resonance until exact resonant point is determined.
(D) Adjust Antenna trimmer (A14) to maximum output.
(E) Readjust Oscillator trimmer (A13) to maximum output.

- 1. HEATING
(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion and contraction of the capacitors and inductances.
(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

- 2. DIAL CALIBRATION
Turn the condenser until the plates are fully meshed, set the pointer (Hour Hand) to 9 and 5 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the line pointing to 12.

- 3. SIGNAL GENERATOR ADJUSTMENT
During the entire alignment procedure the signal input from the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A. V. C. Circuit will remain at the most sensitive point.

- 4. I. F. ALIGNMENT
(A) Set the generator to 465 K.C. and connect the output lead to the control grid of the 6A8 tube through the .05 Mfd. dummy and the generator ground to the chassis ground post.
(B) Set the receiver dial pointer to 600 K.C. and the range switch (C) Connect the output meter across the two primary terminals on the output transformer.
(D) Adjust the I. F. Trimmers A1, A2, A3, A4, A5, and A6 to maximum output.

OCTOBER, 1936
SERVICE DATA

Chassis Type 6M
Receiver Model 631-643

The Grunow Chassis 6M is a six tube, three band heterodyne receiver using 1-6A8 1st Detector and Oscillator, 1-6K7 1st I. F. Amplifier, 1-4K7 2nd I. F. Amplifier, 1-6Q2 2nd Detector, A. V. C. and Audio Amplifier, 1-6F6 Power Output, and 1-5W4 Rectifier. The tuning range is divided into three divisions or bands covering from 550 K.C. to 1750 K.C. on "A," Broadcast Band, 1750 K.C. to 5.5 M.C. on the "B," Police Amateur Band and 5.5 M.C. to 18.2 M.C. on the "C," Foreign Broadcast Band.

SERVICE DATA

CONTINUITY AND VOLTAGE

GENERAL HOUSEHOLD UTILITIES CO.

POWER SUPPLY UNIT

The Power or "B" voltage in this receiver is the popular six volt vibrator type which eliminates the use of "B" batteries and the vibrator is the "plug in" type ordinarily used in automobile receivers. The electrical layout and vibrator socket connections are shown schematically in Fig. 4. UNDER NO CONDITIONS SHALL THE COMMON GROUND POINT BE CHANGED IN THIS UNIT.

BIAS CELLS

The 7 NB Chassis uses "C" bias cell units in both the Detector A.V.C. and Audio Amplification Circuits, one in the Grid of the 1B5 tube and four in the Grid of the 30 tubes.

These cells may have to be replaced occasionally, and when doing so, note that the carbon or (+) side is connected to the ground side of the cell terminal clip.

An indication of a faulty cell will be distorted tone quality. This may be checked by the substitution of new cells in place of the old, or for testing purposes a "C" battery may be used—using a 1½ volt tap for a single cell or 4½ volts for the 4 unit cell.

This bias cell has a voltage of 1½ volts, but due to its low current output it cannot be measured by any ordinary volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was connected and located. This applies particularly to all ground points.

All parts replacements in the R.F. end of the circuit must be exact duplicates of the originals, especially so in the case of R.F. By-pass, or Coupling Condensers.

Any repairs in the R.F. circuit will make a complete realignment of the entire tuned circuit necessary.

ALIGNMENT PROCEDURE

Do not attempt to align the 7 NB Chassis without the proper equipment as the calibration, selectivity and sensitivity absolutely depend upon the conformance to the following instructions.

Alignment trimmer screws are plainly shown in the accompanying illustrations and are numbered in the order of procedure.

1. EQUIPMENT:

- (A) Test Oscillator.
- A modulated oscillator capable of producing signals at the I.F., Broadcast and Short-Wave frequencies.
- (B) Insulated Screw Driver—(All labels or fibre) about 6" long.
- (C) Output Meter.

A meter of sufficient sensitivity to provide a good deflection at low signal strength.

- (D) Dummy Antenna.
- .05 mfd. condenser (I.F. Alignment).
- 200 mfd. condenser (Broadcast Alignment).
- 400 Ohm carbon resistor (18 M.C. Alignment).
- (E) The receiver should be aligned in a location as free from local interference as possible, as static disturbances will cause difficulties in signing the Short-Wave section. A screen room is recommended in order to obtain the best results.

2. CALIBRATION OF THE DIAL:

Turn tuning knob until condensers are fully meshed. The dial pointer (Hour Hand) at this position must be set on the horizontal line of the dial, pointing to 9 and 3 o'clock.

The Band Spreading Pointer (Minute Hand) must be set to the vertical position, pointing to 12 o'clock.

3. Connect the chassis to a fully charged storage battery and allow the set to heat up for 30 to 30 minutes. This heating period is necessary in order to allow all coils and condensers to reach their normal temperatures so that when the alignment is complete, there will be no inductance or capacity changes due to thermal expansion or contraction.

Note: The above also applies to the oscillator.

4. I.F. ALIGNMENT:

(A) Connect signal lead of the oscillator to the control grid of the 6A7 First Detector Tube through a .05 mfd. condenser. Connect the oscillator ground to the chassis ground post.

(B) Set the dial pointer to 1400 K.C. and the range switch at position "A" (Standard Broadcast). Turn the volume control to maximum and tune control to high.

(C) Set the oscillator to 455 K.C. and adjust the signal to as low a value as can be read efficiently on the output meter.

(D) Adjust the I.F. Trimmers in sequence of numbering (1-2-3-4-5-6) until the maximum signal with the lowest input is obtained.

The signal input must be kept as low as possible in order to prevent any A.V.C. action in the receiver.

5. 1400 K.C. ALIGNMENT:

- (A) Set Oscillator to 1400 K.C.
- (B) Turn dial pointer to 1400 K.C. and range switch to position "A" (Broadcast Band).
- (C) Adjust Broadcast Oscillator Trimmer, (A7) Fig. 2, to maximum output.
- (D) Adjust Detector Trimmer, (A8) Fig. 2, to maximum output.

(E) Adjust Antenna Trimmer, (A9) Fig. 2, to maximum output.

6. 600 K.C. ALIGNMENT:

- (A) Set oscillator to 600 K.C.
- (B) Set chassis dial pointer to 600 K.C.
- (C) Adjust the 600 K.C. padding condenser, (A10) Fig. 2, in the direction of signal increase, at the same time rock the tuning condenser back and forth slowly so as to determine the exact point of greatest output.

7. Recheck the 1400 K.C. alignment (Operation 5.) This is necessary because the change in the capacity of the 600 K.C. padder may have slightly unbalanced the 1400 K.C. alignment.

8. 5000 K.C. ALIGNMENT:

- (A) Set oscillator to 5000 K.C.
- (B) Set the Range Switch to position "B" (Police Amateur Band).
- (C) Set the dial pointer to 5000 K.C.
- (D) Adjust the Oscillator Trimmer, (A11) Fig. 2, to maximum output.
- (E) Adjust the Detector Trimmer, (A12) Fig. 2, to maximum output.
- (F) Adjust Antenna Trimmer, (A13) Fig. 2, to maximum output.

9. 18 MEGACYCLE ALIGNMENT:

- (A) Set oscillator to 18 M.C. and connect the output lead to the chassis Antenna post through a 400 ohm resistor.
- (B) Set Range Switch on position "B" (Foreign Reception band).
- (C) Set the dial pointer to 18 M.C.
- (D) Adjust the Oscillator Trimmer, (A14) Fig. 2, to maximum output.
- (E) Adjust the Detector Trimmer, (A15) Fig. 2, to maximum output.
- (F) Adjust the Antenna Trimmer, (A16) Fig. 2, to maximum output.

Note: When adjusting the 18 M.C. Oscillator Trimmer, screw down tightly and then back off until signal is heard.

To obtain the utmost sensitivity on the 18 M.C. Band, it is necessary, when adjusting the Detector Trimmer (A15), to rock the tuning condenser slowly through resonance until the point of maximum output is determined. Return to the Oscillator Trimmer and make any necessary re-adjustment.

SERVICE NOTES

The GRUNOW 7 NB Chassis is a seven tube super-heterodyne receiver, with a vibrator type power supply designed to operate from a 6 volt battery. The major features are three Tuning Ranges, covering Standard Broadcast, Police, Amateur, and Foreign Broadcast bands, A.V.C., a Full Face "Band Spread" Dial and the new Permo-Flux Speaker.

SERVICE DATA

The three tuning ranges of the receiver cover, First, the Standard Broadcast Band (A) from 550 K.C. to 1750 K.C.; Second, the Police Amateur Band (B) from 1750 K.C. to 5500 K.C.; and Third, the Foreign Reception Band (C) from 5.5 M.C. to 18 M.C.

CONTINUITY AND VOLTAGE

Continuity and voltage measurements should be taken from the underside of the chassis. The values shown on the schematic diagram are based on an average and allow the service man to make a quick check of the chassis constants. All tube connections and sockets are shown on the schematic diagram as viewed from the bottom.

RANGE SWITCH

The Range Switch is a three deck multipole low contact resistance switch, used to connect the various coils into their proper circuits, and is designed to entirely isolate the coils, which are not in use, by grounding them. This method makes it possible for the receiver to operate on each of the three tuning ranges at a maximum sensitivity and selectivity.

The Range Switch and Coil Assembly is shown schematically (Fig. 3) with each section and the proper connections to the coil drawn separately so as to enable the service man to check or make necessary repairs with ease. All connection number designations are duplicated on the chassis schematic (Fig. 4).

GENERAL HOUSEHOLD UTILITIES CO.
RADIO SERVICE DEPARTMENT
CHICAGO, U.S.A. RAS 207

This chassis utilizes a "C" bias cell in the control grid of the 6Q7 tube. To check the cell, a new one or a 1½ volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating. When replacing the cell note that the carbon (+) side is connected to the ground side of the terminal clip.

Alignment

8. 1500 K. C. ALIGNMENT (BROADCAST BAND):
- Set the Generator to 1500 K. C.
 - Set the chassis range switch to position "A" and the dial pointer to 1500 K. C.
 - Adjust the Broadcast Oscillator Trimmer A10—Fig. 2—to maximum output.
 - Adjust the Broadcast Detector Trimmer A11—Fig. 2—to maximum output.
 - Adjust the Broadcast Antenna Trimmer A12—Fig. 2—to maximum output.
 - Adjust the Generator to 600 K. C.
 - Set the chassis dial pointer to 600 K. C.
 - Adjust the 600 K. C. Padding Compensator A13—Fig. 2—in the direction of signal increase—at the same time rock the tuning condenser slowly back and forth through resonance until to point of greatest output is obtained on both.
 - Realign 1500 K. C. as instructed in operation No. 8 to correct interaction changes in alignment.
11. 5 M. C. ALIGNMENT (POLICE-AMATEUR BAND):
- Set the generator to 5000 K. C. and connect through a 400 Ohm carbon resistor to the antenna post on the chassis.
 - Set the chassis range switch to position "B" and the dial pointer to 5 M. C.
 - Adjust the Oscillator Trimmer A14—Fig. 2—to maximum output.
 - Adjust the Detector Trimmer A15—Fig. 2—to maximum output.
 - Adjust the Antenna Trimmer A16—Fig. 2—to maximum output.
12. 18 M. C. ALIGNMENT (FOREIGN RECEPTION BAND):
- Set the generator to 18 M. C.
 - Set the chassis range switch to position "C" and the dial pointer to 18 M. C.
 - Adjust the Oscillator Trimmer A17—Fig. 2—to maximum output.
 - Adjust the Detector Trimmer A18—Fig. 2—to maximum output.
 - Adjust the Antenna Trimmer A19—Fig. 2—to maximum output.
- Note: To adjust Oscillator Trimmer correctly screw down tightly and then back off until signal is heard. To obtain the utmost sensitivity on the 18 M. C. Band, it is necessary, when adjusting the Detector Trimmer (A18), to rock the tuning condenser slowly through resonance until the point of maximum output is determined. Return to the Oscillator Trimmer and make any necessary readjustment.

- during the alignment operations.
3. DIAL CALIBRATION:
- Turn the tuning knob until the condensers are fully meshed and set the dial pointer (Hour Hand) to horizontal line pointing to 9 and 3 on the outer edge of the dial chart.
 - Then set the band spreading pointer (Minute Hand) to the vertical line pointing to 12.
4. 455 K. C.—I.F. ALIGNMENT:
- Set the generator to a frequency of 455 K. C., & Osc. tube and the ground lead to the ground post on the chassis.
 - Set the Hour Hand of the chassis to 1500 K. C., turn the volume control full on, set the range switch to the A or Broadcast position and the Tone control to position 1, counter-clockwise.
 - Connect the output meter across the primary terminals of the output transformer.
 - Adjust the I. F. Trimmers, located as shown in Fig. 1; in the order of their numbers, A1, A2, A3, A4 and A5, until the maximum sensitivity is obtained.
- During this and all following alignment operations the generator must be attenuated as the compensators are brought into resonance until the maximum output is obtained with the lowest possible input. This is necessary in order to hold the A. V. C. tube to its highest sensitivity, at which point only, can precise adjustments of the compensators be obtained.
5. 175 K. C. ALIGNMENT (WEATHER BAND):
- Set the generator to a frequency of 175 K. C. and connect the output to the Antenna post of the chassis through a 200 Mmf. condenser.
 - Set the chassis range switch to position "X" and the dial pointer to 175 K. C. on the dial chart.
 - Adjust the 175 K. C. Trimmer A6, as shown on Fig. 2, in the direction of signal increase and at the same time rock the tuning condenser slowly back and forth through resonance until the point of greatest output is obtained.
6. 350 K. C. ALIGNMENT (WEATHER BAND):
- Set the generator to 350 K. C.
 - Set the chassis dial pointer to 350 K. C.
 - Adjust the Oscillator Trimmer A7—Fig. 2—to maximum output.
 - Adjust the Detector Trimmer A8—Fig. 2—to maximum output.
 - Adjust the Antenna Trimmer A9—Fig. 2—to maximum output.
7. CHECK 175 K. C. ALIGNMENT so as to correct any alignment change which may have occurred due to the slight interaction between the 350 K. C. and 175 K. C. compensators.

- BEACON EYE SENSITIVITY ADJUSTMENTS
- The 6E5 Beacon Eye tube is designed to give the best results with the proper size antenna. However, where a full sized antenna cannot be erected or an inside antenna must be used, a type 6E5 Beacon Eye Tube can be substituted by making the following changes in the wiring of the circuit:
- Refer to schematic diagram Fig. 4 and disconnect the "Green" grid wire at point "A" and connect to point "B." This change can be made quickly and will give a maximum sensitivity on the weaker signals.
- REPAIRS
- When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was connected and located. This applies particularly to all ground points.
- All parts replacements in the R. F. end of the circuit must be exact duplicates of the originals, especially so in the case of R. F., By-pass, or Coupling Condensers.
- Any repairs in the K. F. circuit will make a complete realignment of the entire tuned circuit necessary.
- ALIGNMENT PROCEDURE
- Do not attempt to align the 8H chassis without the proper equipment as the selectivity, sensitivity, and calibration depend absolutely upon the exact conformance to the following instructions. Each step in the alignment operation is given in its proper sequence and under no conditions should this order be changed.
1. EQUIPMENT:
- Signal Generator.
 - Modulated oscillator capable of generating signals of frequencies from 150 kilocycles to 18 Megacycles.
 - Non-Metallic screw driver (Alignment Tool).
 - An output meter of sufficient sensitivity to provide a good deflection at low signal input.
 - Dummy Antenna.
 - 50 Mfd. Condenser.
 - 200 Mmf. Condenser.
 - 400 Ohm Carbon Resistor.
2. HEATING:
- Connect the receiver to a 115 V. A. C. source and allow the chassis to warm up for a period of from 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion or contraction of the capacitors and inductances in the various tuned circuits.
 - The signal generator should also be warmed up before using in order to prevent any frequency changes

- SERVICE DATA
- The GRUNOW 8 H Chassis is an eight tube four band superheterodyne receiver using 1—6K7 R. F. amplifier, 1—6A8 first detector and oscillator, 1—6X7 I. F. amplifier, 1—6H6 second detector and A. V. C., 1—6E5 beacon eye, and 1—5Z4 rectifier.
- The frequency coverage is divided into four separate bands, the "X" or weather band 150 to 410 K. C., "A" or Standard Broadcast Band 550 to 1720 K. C., "B" or Police-Amateur Band, 1720 to 5500 K. C., and the Foreign Reception Band 5.5 M. C. to 18.5 M. C.
- CONTINUITY AND VOLTAGE
- Continuity and voltage measurements should be taken from the underside of the chassis in order to more easily follow the schematic diagram. All sockets are shown on the schematic diagram and have been drawn bottom view. Each element is enumerated and in the exact relationship to the tube guide pin in order to help the service man make a quick and correct check of the chassis constants.
- RANGE SWITCH AND COIL ASSEMBLY
- The range switch and coil assembly used on the 8H chassis has been designed to allow the receiver to operate on all four bands with maximum sensitivity and selectivity. Each set of coils when not in use is isolated from the coils in use by shorting both ends and grounding through a condenser. This method eliminates all possibilities of open end inductive losses and harmonic pickup.
- Schematic diagram Fig. 3 illustrates in detail each section of the range switch with its coil and the proper connections, whose enumerations are duplicated on the chassis schematic diagram.

GENERAL HOUSEHOLD UTILITIES CO.

MODEL 941 Chassis 9E Alignment, Notes

INTRODUCTION

The Grunow Chassis 9E is a nine tube, four band receiver, using 1—6K7 R.F. Amplifier, 1—6A8 1st Detector and Oscillator, 1—6K7 I.F. Amplifier, 1—6H6 2nd Detector and A.V.C., 1—6C5 Audio Amplifier, 2—6F6 Power Output, 1—5Z4 Rectifier and 1—6E5 "Beacon Eye" Resonance Indicator.

The frequency coverage is divided into four separate tuning ranges or bands; the "X" Weather Band, 150 K.C. to 410 K.C.; "A" Broadcast Band, 550 K.C. to 1720 K.C.; "B" Police-Amateur Band, 1720 K.C. to 5.5 M.C., and the "C" Foreign Broadcast Band, 5.5 M.C. to 18.2 M.C.

**Chassis Type 9E
Receiver Model 941
Speaker Type 1210-A-2**

- (A) Set the generator to 350 K.C.
(B) Set the chassis dial pointer to 350 K.C.
(C) Adjust Oscillator trimmer A7, Detector trimmer A8, and Antenna trimmer A9 to maximum output.

7. Check 175 K.C. Alignment so as to correct any alignment change which may have occurred due to the slight inter-action between the 350 and 175 K.C. trimmers.

8. 1500 K.C. ALIGNMENT (Broadcast Band):

- (A) Set the generator to 1500 K.C.
(B) Set the chassis range switch to position "A" and the dial pointer to 1500 K.C.
(C) Adjust Oscillator trimmer A10, Detector trimmer A11, and Antenna trimmer A12 to maximum output.

9. 600 K.C. ALIGNMENT (Broadcast Band):

- (A) Set the generator to 600 K.C.
(B) Set the dial pointer to 600 K.C.
(C) Adjust the 600 K.C. padding compensator A13 in the direction of the signal increase—at the same time rock the tuning condenser slowly back and forth thru resonance until the point of greatest output is obtained.

10. Realign 1500 K.C. as instructed in operation No. 8 to correct inter-action changes in alignment.

11. 5 M.C. ALIGNMENT (Police-Amateur Band):

- (A) Set the generator to 5 M.C. and connect thru a 400 ohm carbon resistor to the antenna post on the chassis.
(B) Set the chassis range switch to position "B" and the dial pointer to 5 M.C.
(C) Adjust Oscillator trimmer A14, Detector trimmer A15 and Antenna trimmer A16 to maximum output.

To adjust Oscillator trimmer correctly, back trimmer A14 out as far as it will go (minimum capacity) then adjust until signal is heard.

12. 18 M.C. ALIGNMENT (Foreign Broadcast Band):

- (A) Set the generator to 18 M.C.
(B) Set the chassis range switch to position "C" and the dial pointer to 18 M.C.
(C) Adjust Oscillator trimmer A17, Detector trimmer A18 and Antenna trimmer A19 to maximum output.

Note: To adjust Oscillator trimmer correctly, screw down tightly and then back off until signal is heard. To obtain the utmost sensitivity on the 18 M.C. Band, it is necessary, when adjusting the Detector trimmer (A18) to rock the tuning condenser slowly thru resonance until the point of maximum output is determined. Return to the Oscillator trimmer and make any necessary readjustment.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

ALIGNMENT PROCEDURE

1. HEATING:

(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to thermal expansion and contraction of capacitors and inductances.

(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

2. DIAL CALIBRATION:

Turn the condenser until the plates are fully meshed, set the pointer (Hour Hand) to 9 and 3 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the line pointing to 12.

3. SIGNAL GENERATOR ADJUSTMENT:

During the entire alignment procedure, the signal input from the generator to the receiver must be continually attenuated at the generator, as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A.V.C. circuit will remain at the most sensitive point.

4. 455 K.C.—I.F. ALIGNMENT:

(A) Set the generator to a frequency of 455 K.C., connect the output to the control grid of the 6A8 1st Detector and Oscillator tube thru .05 mfd. dummy and the ground lead to the ground post on the chassis.

(B) Set the dial pointer to 600 K.C., turn the volume control full on, set the range switch to the "A" or Broadcast position and the tone control to position 3 clockwise.

(C) Connect the output meter across the primary terminals of the output transformer.

(D) Adjust the I.F. trimmers, located as shown in Fig. 1, in the order of their numbers, A1, A2, A3, A4 and A5, until maximum sensitivity is obtained.

5. 175 K.C. ALIGNMENT (Weather Band):

(A) Set the generator to a frequency of 175 K.C. and connect the output to the Antenna post of the chassis thru a 200 mmfd. dummy.

(B) Set the chassis range switch to position "X" and the dial pointer to 175 K.C. on the dial chart.

(C) Adjust the 175 K.C. trimmer A6, as shown on Fig. 2, in the direction of signal increase and at the same time rock the tuning condenser slowly back and forth thru resonance until the point of greatest output is obtained.

6. 350 K.C. ALIGNMENT (Weather Band):

SERVICE DATA

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 4) are shown bottom view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the volume control "full on" and the range switch in position "C" using a 1000 ohm per volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that parts replacements are made in EXACTLY the same way as the original parts were located, and connected. This applies particularly to ground points.

All parts replacements in the R.F. end of the circuit must be exact duplicates of the originals, especially so in the case of coils, R.F. by-pass or coupling condensers.

Any repairs in the R.F. circuit will make a complete realignment of the tuned circuit necessary.

BEACON EYE SENSITIVITY ADJUSTMENTS

The 6E5 "Beacon Eye" tube is designed to give the best results with the proper size antenna. However, where a full size antenna cannot be erected or an inside antenna must be used, a type 6G5 tube can be substituted by making the following changes in the wiring of the circuit:

Refer to schematic diagram Fig. 4 and disconnect the "green" grid wire at point "A" and connect to point "B." This change can be made quickly and will give a maximum sensitivity on weaker signals.

HIGH LINE VOLTAGE

For use in localities having consistent high line voltage (120-130 V.) an extra primary lead has been provided on the Power Transformer. To make this change, merely remove the green lead from the terminal strip and connect the taped yellow lead to its place.

CIRCUIT ALIGNMENT EQUIPMENT

Do not attempt to align this chassis without the equipment specified below:

1. Signal Generator—
A modulated oscillator capable of delivering frequencies from 175 K.C. to 18.2 M.C.
2. Alignment Tool—
A non-metallic screw driver.
3. Dummy Antenna—.05 Mfd. Condenser (I.F. Alignment).
200 Mmfd. Condenser (Broadcast Alignment).
400 Ohm Carbon Resistor (Short Wave Alignment).
4. Output Meter—
A meter of sufficient sensitivity to give a good deflection at very low signal input.

Chassis 11A

INTRODUCTION

The following characteristics apply to the Grunow Radio—Chassis Type 11A:

This model is an 11 tube superhetrodyne All Wave (540 to 21,500 K.C.) Receiver using 1-6D6 tube as an R.F. Amplifier, 1-6A7 tube as a 1st Detector or mixer, being electronically coupled to a 76 oscillator tube. 1-6D6 tube as an I.F. amplifier with a frequency of 262 K.C., 1-85 tube (double diode triode) used as a diode detector or signal rectifier, delayed automatic volume control (AVC) and audio amplifier. The 85 tube feeds a pair of 76 tubes, connected in parallel, these tubes act as a driver stage, driving a pair of 45 tubes in class A prime push pull, delivering an undistorted output of approximately 9 watts. The 76 driver tubes receive their bias through the 164 ohm section of the candohm resistor. Oscillation in the driver stage is prevented by the 100,000 ohm resistor in the grid of the second 76 tube. The 45 tubes receive their bias through the voltage drop in the speaker field. A separate 76 tube is used as the Signal Beacon or Beat Oscillator, plate voltage of the Signal Beacon being applied by closing the switch on the tone control. The rectifier tube is a 5Z3, the output of which is well filtered through the choke action of the speaker field, the tuned filter choke, and the 4-8 mfd. electrolytic condensers.

The broadcast section of the receiver consists of the following 4 tuned circuits: R.F. input, bi-selector, mixer input and oscillator. These circuits are tuned with a 4-gang variable condenser of rugged construction.

The short wave section of the receiver consists of 3 tuned circuits, the bi-selector being cut out to prevent losses when the receiver is working at the higher frequencies.

The Signal Beacon is a beat oscillator using a 76 tube, and is a feature of the 11A Chassis. When this tube is brought into operation it acts as a local oscillator and beats against the incoming signal. The presence of a station's signal will be indicated by a high pitched "whistle", becoming lower in pitch as "resonance", or exact tuning, is approached. The Signal Beacon note becomes very low and finally reaches zero; at this point the receiver is said to be tuned to "zero beat", which indicates that it is tuned exactly to the station. The Signal Beacon is also used to receive telegraph or continuous wave signals.

The remainder of the circuit is typical and has been designed along the lines of what is considered the best engineering practice to date. Parts are all oversize and of the finest quality.

CHICAGO, ILLINOIS

INTRODUCTION

The Grunow Chassis 11G is an eleven tube, three band superheterodyne receiver with a full face band spread dial and a Beacon Eye tuning indicator.

CIRCUIT DESCRIPTION

The circuit and tube complement of the Grunow 11G Chassis is as follows: 1-6K7 R. F. Amplifier, 1-6A8 1st Detector and Oscillator, 1-6K7 1st I. F. Amplifier, 1-6K7 2nd I. F. Amplifier, 1-6H6 2nd Detector and A. V. C., 1-6C5 Phase Inverter Driver, 1-6C5 Audio Driver, 2-6F6 Power Output, 1-6G5 Beacon Eye and 1-5Z3 Rectifier.

Separate coils are used in the Antenna and Oscillator circuits for each tuning range and have a continuous frequency coverage from 545 K. C. to 1750 K. C. on the "B" Broadcast Band, 1750 K. C. to 5.8 M. C. on the "P" Police Amateur Band and 5.5 M. C. to 18.2 M. C. on the "F" Foreign Broadcast Band.

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 3) are shown bottom view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with

a line voltage of exactly 115V. the volume control full on and the range switch on position "B" using a 1000 ohms per volt meter.

REPAIRS

When servicing this chassis it is **IMPERATIVE** that the service man make all parts replacements in **EXACTLY** the same way as the original part was located and connected. This applies in particular to all ground points. All parts replacements in the R. F. end of the circuit must be exact duplicates of the originals especially so in the case of coils, R. F. by-pass or coupling condensers. Any repairs in the R. F. circuit will make a complete realignment of the entire tuned circuit necessary.

POWER TRANSFORMER

For use in localities having consistent high voltage (120-130 V.) an extra primary lead has been provided on the Power Transformer. Remove the one line switch lead which is soldered to the green transformer lead (A) and solder to the dummy lug (B) on which the brown transformer lead is soldered. The connections (A) and (B) are shown on the schematic diagram (Fig. 3).

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align this chassis without the proper equipment as the sensitivity, selectivity, and calibration absolutely depend on the exact conformance to the following instructions. Each step in the alignment operation is given in its proper sequence and under no conditions should this order be changed. The chassis should be aligned in a location free from local interference (motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulty when the short wave section is adjusted. A screen room is recommended

1. EQUIPMENT

(A) Signal Generator.
A modulated oscillator capable of generating signals from 465 K. C. to 18 megacycles.

(B) Non-metallic screw-driver (Alignment Tool).

(C) Output Meter.

A standard type output meter with sufficient sensitivity to give a good deflection with a small signal input.

(D) Dummy Antenna.

.05 Mfd. condenser—(I. F. Alignment)

200 Mmfd. condenser—(Broadcast Alignment)

400 Ohm carbon resistor (Short Wave Alignment)

.002 Mfd. condenser (I. F. Rejector Filter Alignment)

2. HEATING

(A) Connect the receiver to a 115 V. source and allow the chassis to warm up to a period of 20 to 30 minutes. This is necessary to eliminate possible alignment variations due to thermal expansion and contraction of the capacitors and inductances in the various tuned circuits.

(B) The signal generator should be warmed up also in order to prevent any frequency changes during alignment.

3. DIAL CALIBRATION

(A) Turn the tuning knob until the condensers are fully meshed and set the dial pointer (Hour Hand) to the horizontal line pointing to 9 and 3 on the outer dial scale.

(B) Set the band spreading pointer (Minute Hand) to the vertical line pointing to 12.

Note: During all of the following alignment operations the signal generator must be attenuated as the compensators are brought into resonance until the maximum output is obtained with the lowest possible input. This is necessary in order to hold the A. V. C. tube to its highest sensitivity at which point only can precise adjustment of the trimmers be had.

4. I. F. ALIGNMENT

(A) Connect the Output Meter across the primary terminals of the output transformer.

(B) Set the signal generator to 465 K. C. and connect the output to the grid of the 6A8 oscillator tube through a .05 mfd. condenser. Connect the generator ground lead to the ground post on the receiver.

(C) Set the receiver range switch to position "B" the dial pointer to 600 K. C. and the volume control full on.

(D) Adjust the I. F. Trimmers A1, A2, A3, A4, A5, and A6 to maximum output.

5. 1500 K. C. ALIGNMENT

(A) Set the generator to 1500 K. C. and connect the output to the antenna post on the chassis through a 200 Mmfd. condenser.

(B) Set the receiver dial pointer to 1500 K. C.

(C) Adjust the trimmers A7-Oscillator, A8-Detector and A9-Antenna to maximum output.

6. 600 K. C. ALIGNMENT

(A) Set the generator to 600 K. C.

(B) Set the receiver dial to 600 K. C.

(C) Adjust the trimmer A10 to maximum output and at the same time rock the tuning condenser slowly back and forth through resonance until the exact resonant point is determined.

7. 5000 K. C. ALIGNMENT

(A) Set the generator to 5000 K. C. and connect the output to the Antenna post on the chassis through a 400 Ohm carbon resistor.

(B) Set the receiver dial pointer to 5000 K. C. and the range switch to position "P"

(C) Adjust the trimmers A11-Oscillator and A12-Detector to maximum output.

8. 18 M. C. ALIGNMENT

(A) Set generator to 18 M. C.

(B) Set receiver dial pointer to 18 M. C. and the range switch to position "F."

(C) Screw the Oscillator trimmer (A13) down tightly and slowly back off until signal is heard.

(D) Adjust the Antenna trimmer (A14) to maximum output and at the same time rock the tuning condenser slowly back and forth through resonance until the exact resonant point is determined.

(E) Return to Oscillator trimmer (A13) and repeat operations C. & D.

9. REJECTOR FILTER ALIGNMENT

(A) On 11G chassis having the I. F. Rejector Filter the trimmer will be found on the rear of the chassis near the antenna post.

(B) This filter is aligned at a frequency of 465 K. C. and must NOT be peaked until the rest of the circuit has been completely aligned.

(C) Set generator to 465 K. C. and connect the output to the antenna binding post on the receiver through a .002 mfd. condenser.

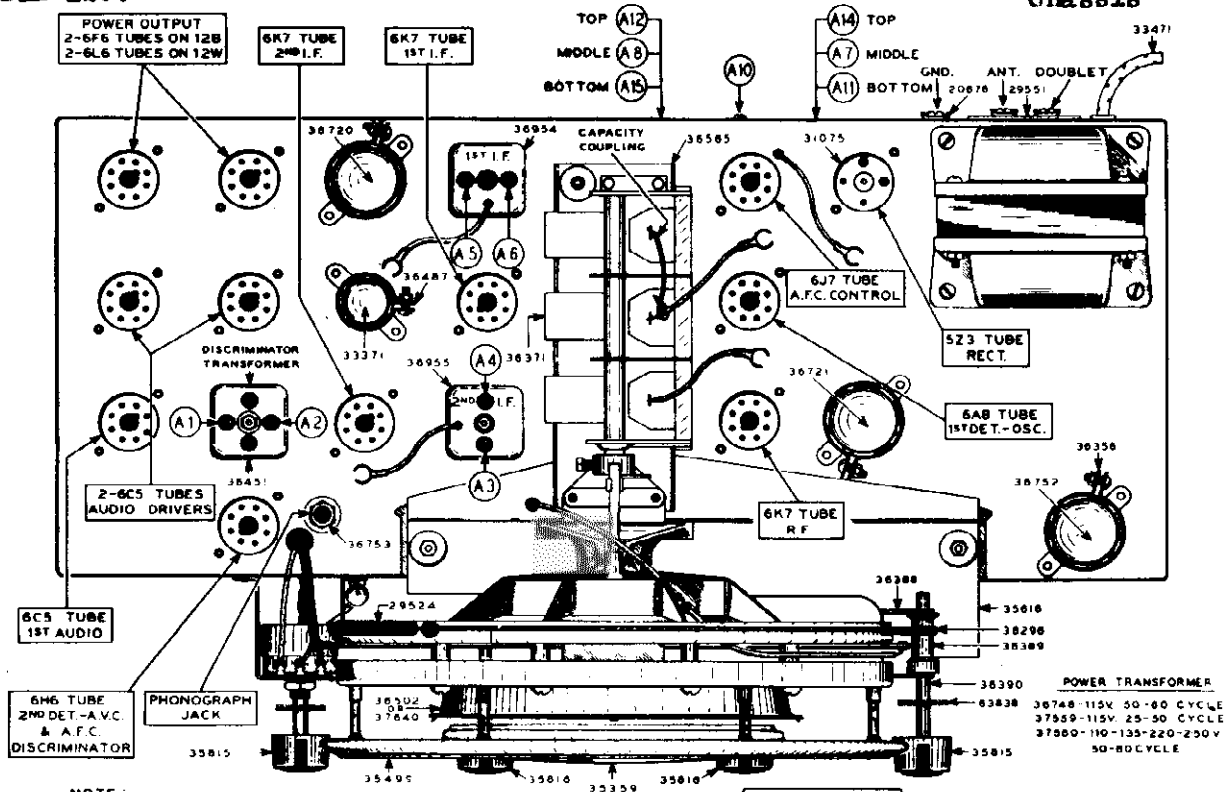

(D) Set the receiver dial pointer to 600 K. C. and the range switch to position "B."

(E) With a strong signal input adjust the trimmer to a *minimum* reading on the output meter.

CIRCUIT ALIGNMENT PROCEDURE

Do not attempt to align this chassis without the proper equipment as the sensitivity, selectivity, and calibration absolutely depend on the exact conformance to the following instructions. Each step in the alignment operation is given in its proper sequence and under no conditions should this order be changed. The chassis should be aligned in a location free from local interference (motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulty when the short wave section is adjusted. A screen room is recommended.

1. EQUIPMENT.

- (A) Signal Generator.
- (B) A modulated oscillator capable of generating signals from 465 K.C. to 18 Mcgacycles, having an output of at least .10 volt.
- (C) Non-metallic screw-driver (Alignment Tool).
- (D) Output Meter.
- (E) A standard type output meter with sufficient sensitivity to give a good deflection with a small signal input.
- (F) Discriminator Meter.

A galvanometer with sufficient sensitivity to read the current swing of the discriminator circuit. A type No. 699 Weston Galvanometer or equivalent is recommended. It is also suggested that a variable shunt of approximately 200 Ohms (wire wound rheostat) be connected across the galvanometer until approximate balance is reached. The shunt will also act as a safety device and "keeper" when the meter is not in use.

(E) Dummy Antenna.

- .05 Mfd. condenser (I.F. Alignment).
- 200 Mmfd. condenser (Broadcast Alignment).
- 400 Ohm carbon resistor (Short Wave Alignment).

2. HEATING.

- (A) Connect the receiver to a 115 V. A.C. source and allow the chassis to warm up for a period of 20 to 30 minutes. This is necessary to eliminate possible alignment variations due to thermal expansion or contraction of the capacitors and inductances in the various tuned circuits.
- (B) The signal generator should be warmed up also, in order to prevent any frequency changes during alignment.

3. DIAL CALIBRATION.

- (A) Turn the tuning knob until the condensers are fully meshed and set the dial pointer (Hour Hand) to the horizontal line pointing to 9 and 3 on the outer dial scale.
- (B) Set the band spreading pointer (Minute Hand) to the vertical line, pointing to 12.

4. DISCRIMINATOR ALIGNMENT.

- (A) Set the signal-generator to a frequency of 465 K.C., connect the output through an .05 mfd. condenser to the control grid of the 6K7-2nd I. F. tube. Connect

the ground lead to the ground post on the chassis.

- (B) Turn range switch to broadcast position (B), turn volume control full off and set dial pointer to 600 K.C.
- (G) Adjust Discriminator primary (A1 or A2) to maximum swing on galvanometer (either positive or negative).

(H) Re-align secondary trimmer to position of zero current. Check signal-generator to be sure frequency has not changed. Do not re-adjust primary unless the entire operation above is repeated.

- (I) Vary the frequency of the signal-generator to be certain that discriminator pointer rests at zero at exactly 465 K.C. Check to determine the maximum current on both sides of resonance—maximum positive current should equal maximum negative current.

Note: Discriminator alignment as outlined above is the accepted and most satisfactory method of obtaining an accurate adjustment. However, if a signal-generator of at least 10 volt output is not available, fair results can be obtained by introducing the signal through the grid of the 6A8 tube. If this method is used, the A.F.C. switch must be on "STD." position (A.F.C. circuit inoperative). This method is not recommended for best results.

5. I.F. ALIGNMENT—465 K.C.

- (A) Set the signal-generator to a frequency of 465 K.C., connect the output through an .05 Mfd. condenser to the control grid of the 6A8-1st Detector-Oscillator tube and the ground lead to the ground post on the chassis.
- (B) Adjust the I.F. Trimmers A3, A4, A5 and A6 to maximum output and at the same time attenuate the signal at the generator so as to have a minimum signal input to the receiver at all times during this and the following operations.

6. 1500 K.C. ALIGNMENT.

- (A) Connect the output of the generator to the antenna post of the receiver through a 200 Mmfd. condenser and set the frequency at 1500 K.C.
- (B) Set the dial pointer of the receiver to 1500 K.C.
- (C) Adjust broadcast trimmers (A7) Oscillator, (A8) Detector and (A9) Antenna to maximum output.
- (C) Connect the galvanometer to the two cathodes of the 6H6 Discriminator Tube.

- (D) Attenuate signal-generator to maximum output, being certain that the frequency remains at 465 K.C.
- (E) Determine primary and secondary of Discriminator transformer (A1 or A2) by touching the trimmer screws with a metal screw driver. When the metal comes in contact with the screw on the secondary trimmer, the galvanometer will fluctuate.

- (F) With alignment tool back off trimmer screw of Discriminator secondary (A1 or A2) until trimmer is wide open.

7. 600 K.C. ALIGNMENT.

- (A) Set the generator frequency to 600 K.C.
- (B) Set the receiver dial pointer to 600 K.C.
- (C) Adjust the 600 K.C. padder (A10) in direction of signal increase and at the same time rock tuning condenser back and forth through resonance; until the point of exact resonance is determined. This point does not have to be exactly 600 K.C. dial setting.

- 8. Repeat 1500 K.C. alignment operation No. 6, to correct any slight change which may have occurred due to the variation of the 600 K.C. padder.

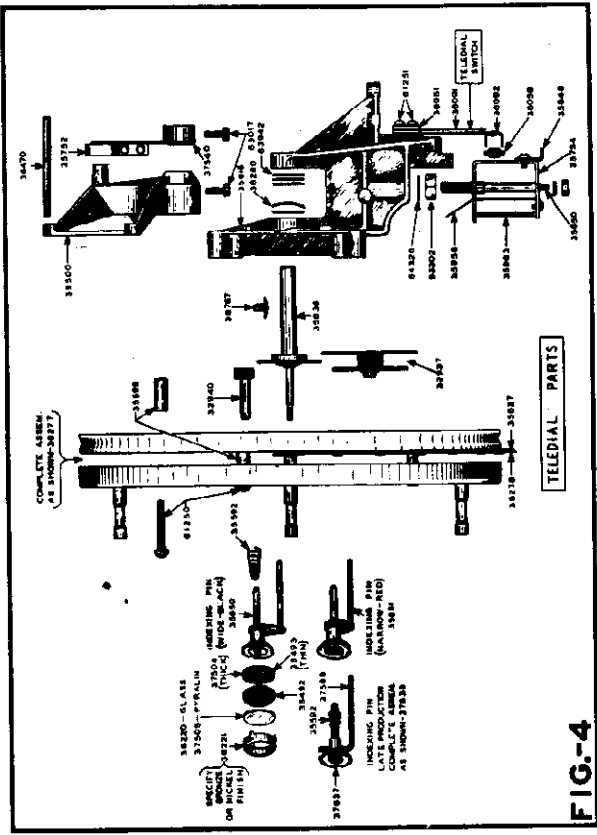

9. 5000 K.C. ALIGNMENT.

- (A) Set the generator to 5000 K.C. and connect the output to the antenna post of the receiver through a 400 Ohm carbon resistor.
- (B) Set the receiver range switch to the Police-Amateur position and the dial pointer to 5000 K.C.

- (C) Adjust the trimmers (A11) Oscillator, (A12) Detector and (A13) Antenna to maximum output. When adjusting (A11) use signal with least capacity—trimmer farthest open.

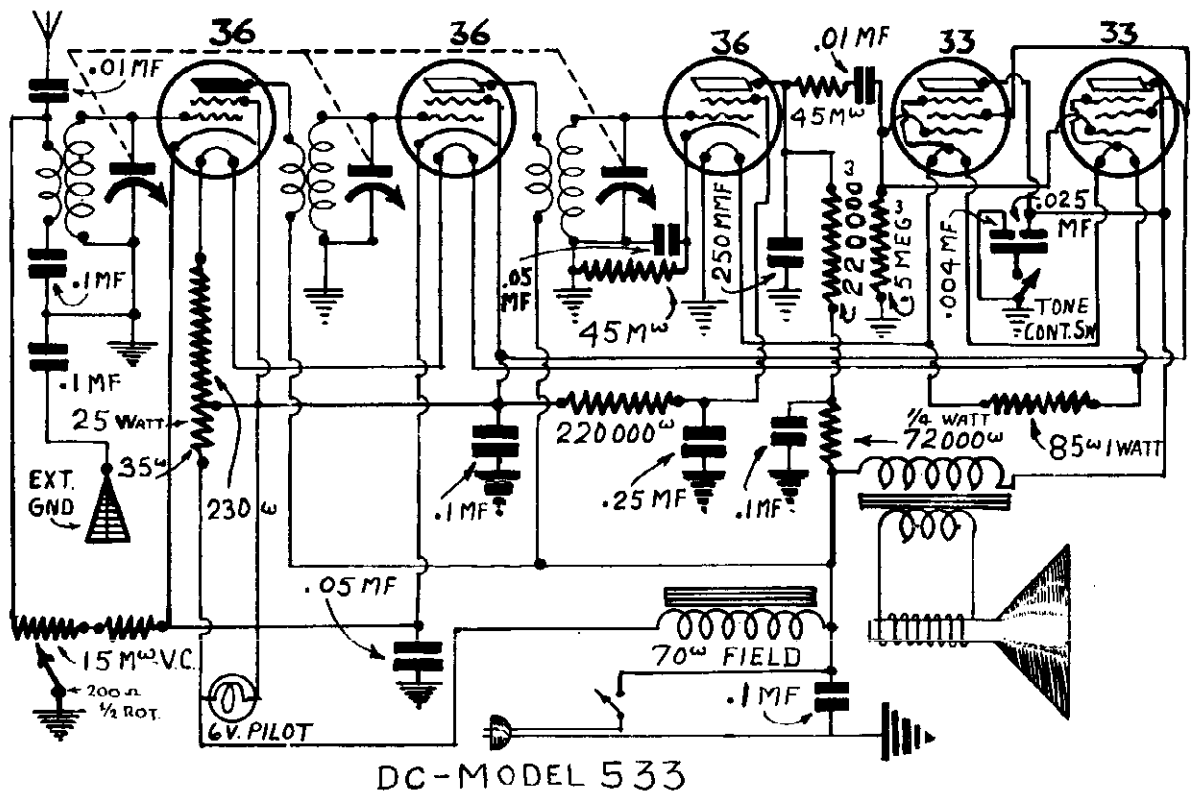

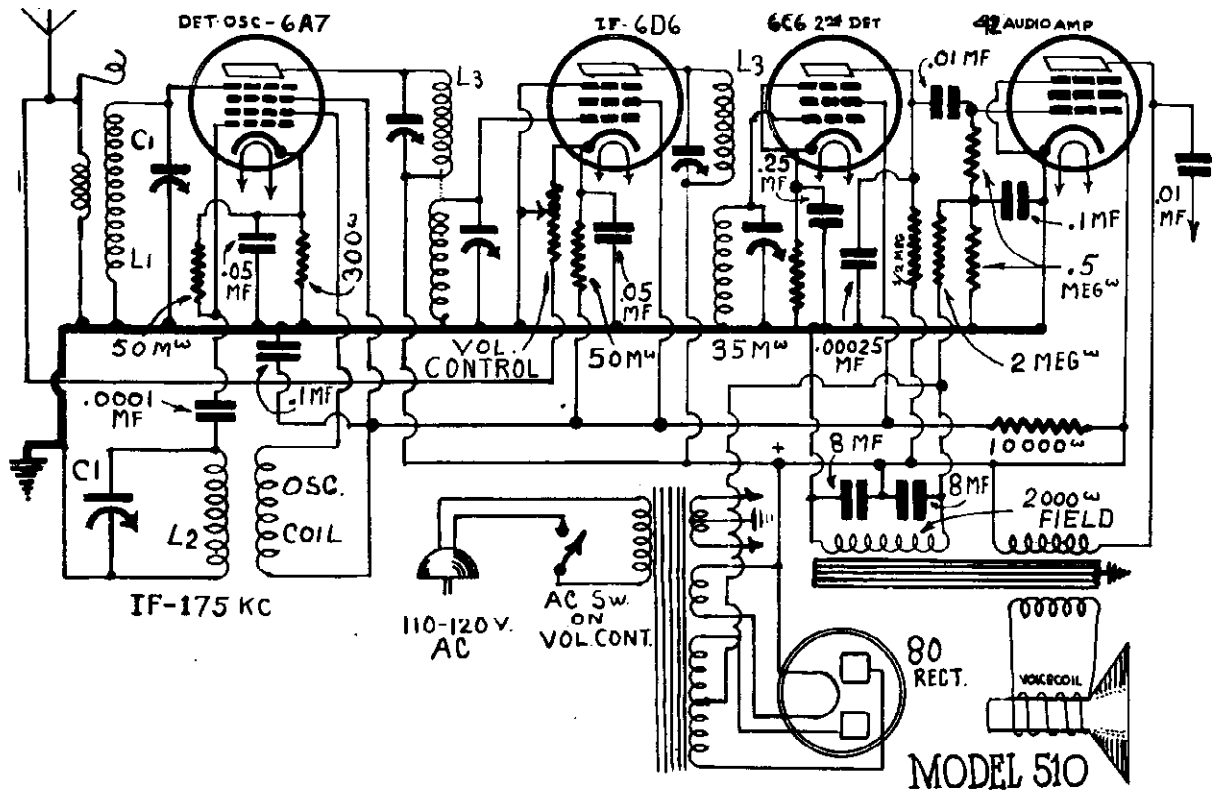

10. 18 M.C. ALIGNMENT.

- (A) Set generator to 18 M.C.
- (B) Set the receiver range switch to the Foreign Broadcast position and the dial pointer to 18 M.C.
- (C) Screw Oscillator Trimmer (A14) down tightly and then back off until signal is heard. Adjust to maximum output.
- (D) Adjust the Detector Trimmer (A15) and at the same time rock the tuning condenser slowly back and forth through resonance until the point of maximum output is determined.
- (E) Return to Oscillator Trimmer (A14) and re-adjust, if calibration has changed.
- (F) Adjust Antenna Trimmer (A16) until maximum output is obtained.

DESCRIPTION

TUBES:

The tube complement of this chassis is as follows:
 1 Type 1A6—first detector oscillator.
 1 Type 1A4—I.F. amplifier. 465 K. C.
 1 Type 30—second detector. A. V. C.
 1 Type 1A4—audio.
 1 Type 950—output.

FOR BEST OPERATION THIS RECEIVER MUST HAVE AN OUTSIDE AERIAL NOT OVER FIFTY FEET LONG INCLUDING THE LEAD IN.

The following batteries are needed.
 2.....45 volt "B" Batteries.

1.....3 Volt Dry "A" Battery or 2 Volt Storage Battery.

ALIGNING I.F. TRANSFORMERS: (465 K.C.)

1. With volume control full on and with variable condenser at its minimum capacity position, plates entirely out of mesh, and with external oscillator set at 465 K.C. connected in series with a .1 mfd. condenser, to the grid of the 1A6 tube (cap at top of tube), adjust I.F. transformers, parts number 108-67 and 108-68, to resonance. Both of these transformers have two (2) adjustments each, they are accessible from the tops of the cans (for location see top view).
 Use as a resonance indicator an output meter connected across the outside terminals of the speaker or by means of an adapter to the plate and screen of the type 950 output tube. Maximum deflection of the volt meter indicates resonance.
 Use only enough signal to get a readily readable output.
 A low range output meter or the low scale of a multi-range meter should be used.

BROADCAST BAND ALIGNMENT:

1. Set external oscillator to 1720 K.C. and connect it in series with a 200 mmfd. condenser to the antenna and ground posts.
 (a) With variable condenser in its minimum capacity position, plates entirely out of mesh, adjust oscillator trimmer (rear section of variable condenser) to resonance.
 (b) Re-set external oscillator to 1400 K.C. Rotate variable condenser, pick up signal and adjust antenna trimmer (front section of variable condenser) to resonance.
 (c) Re -set external oscillator to 600 K.C., move dial pointer to 600 K.C., and adjust series pad, part number 124-14 (see top view), to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.
 (d) Check for sensitivity at 1400, 1000, 600 K.C. DO NOT BEND PLATES.

ALIGNING I.F. TRANSFORMERS: (465 K. C.):

- Part No. 108-83B Output I.F. Transformer
 - Part No. 108-82B Input I.F. Transformer
- These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see Fig. 1).
- With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
 - Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-83B) to resonance.
 - Move oscillator output clip from grid of 6K7G to grid of 6A8G and adjust input I.F. transformer (No. 108-82B) to resonance.
 - With oscillator still connected to 6A8G, readjust output I.F. transformer (108-83B) if necessary.

- The type and function of each tube is as follows:
- Type 6A8G Pentagrid Mixer, First Detector-oscillator.
 - Type 6K7G Remote Cut-Off Pentode, I.F. Amplifier (K.C.)
 - Type 6R7G. Duplex Diode Triode Second Detector, and First Audio.
 - Type 25L6G Beam Output Amplifier.
 - Type 25Z6G High Vacuum Rectifier.
 - Type L49B Ballast Tube.

R.F. ALIGNMENT: (535-1720 K.C.)

- With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mmf. condenser to the antenna lead and chassis ground and make the following adjustments:
 - With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance. This adjustment is on the top of rear section of variable gang condenser. (See Fig. 1).
 - Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. (Top of front section of gang condenser).
 - Check sensitivity at 600 and 1000 kilocycles.

Alignment, Notes

GOODYEAR SERVICE

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-103 Output I.F. Transformer

Part No. 108-104 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser in its minimum capacity position, plates entirely out of mesh, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-103) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7G to grid cap of 6A8G and adjust input I.F. transformer (No. 108-104) to resonance.

SHORT WAVE BAND ALIGNMENT:

2000 to 7000 Kilocycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 6 megacycles and connected in series with "Dummy 3" to the antenna and ground leads, make the following adjustments:

(a) Move dial pointer to 6 megacycles and adjust short wave oscillator trimmer to resonance.

This adjustment is the trimmer mounted on the top of rear section of the variable gang condenser (see Fig. 1, top view).

(b) Adjust short wave antenna trimmer (Adjustment Number 1), to resonance (see Fig. 3, bottom view).

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with

"Dummy 2" to antenna and ground leads make following adjustments:

(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 3, see bottom view of chassis, Fig. 3).

(b) Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 2), to resonance.

(c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 4), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).

(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

(e) Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

ANTENNA AND GROUND LEADS:

For the best results an outside antenna approximately 75-100 feet long including the lead-in should be used. It should be erected as high as possible and as far from surrounding objects as practical. Both the antenna and lead-in should be placed at right angles to street car lines and incoming power lines and as far from any electrical apparatus which may be in the vicinity (such as elevator motors) as practical.

An inside antenna is not recommended, although it occasionally may serve as a temporary installation especially near powerful broadcasting stations. This type of antenna, however, will not be satisfactory in buildings of steel construction.

Reception on the short wave band can be sometimes improved by means of an approved doublet antenna.

This radio will operate without a ground; however, a good ground by means of an approved clamp to water or steam (not gas) pipes or to a pipe driven in the ground will often reduce noise pick-up.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

DESCRIPTION:

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes:

1—Type 6A8G Pentagrid mixer, first detector-oscillator.

1—Type 6K7G Remote cut-off pentode I.F. amplifier (465 K.C.)

1—Type 6Q7G duplex diode triode second detector, A.V.C. and audio.

1—Type 6F6G—pentode output amplifier.

1—Type 5Y3G or 5W4—high vacuum rectifier.

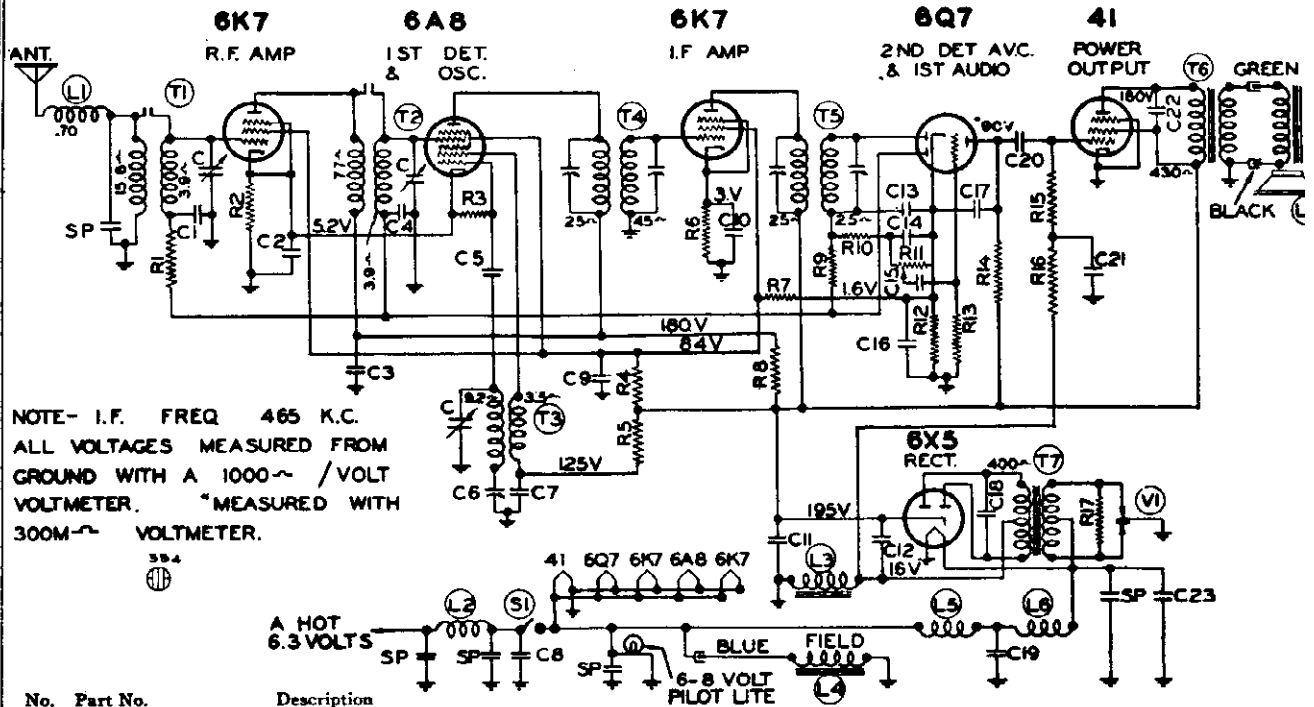

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

BROADCAST ALIGNMENT

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. in series with broadcast dummy to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is on the middle section of the three-gang condenser—see top view, Fig. 2).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust R.F. and antenna trimmers to resonance (see top view, Fig. 2).
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to and fro, at the same time adjusting series pad for maximum gain. This adjustment is accessible from the top of chassis—see top view.
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again. Check for sensitivity at 1000 K.C.

CONNECTIONS TO BATTERY

The battery cable, number 107-82, (red wire with fuse receptacle at one end and terminal lug at other end) must be connected to battery terminal of ammeter. At the same time connect ammeter capacitor, number 148-3, to battery terminal of ammeter, other end of condenser to any convenient grounded screw on back of instrument panel. Make certain that insulating sleeve is slipped over fuse when fuse is placed in receptacle, before connecting to short battery cable from receiver.

When connected properly, the discharge due to current drawn by the receiver should not indicate on the ammeter. This is important, since if improperly connected, as shown by the deflection of ammeter, additional motor interference may be encountered.

MODEL 741

Alignment, Trimmers

GOODYEAR SERVICE

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-106 Output I.F. Transformer
Part No. 108-105 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-106) to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6A8G and adjust input I.F. transformer (No. 108-105) to resonance.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:

(a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly, Fig. 3.)

(b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)

(c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)

(d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

(e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave

antenna (Adjustment number 6) to resonance.

(b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.

(c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

(a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.

(b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.

(c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

(d) Recheck broadcast band alignment.

ANTENNA AND GROUND LEADS:

You will notice three wires coming out of the back of the chassis, — the yellow wire and the black with yellow tracer wire are used for doublet antenna connections. The black wire is the ground connection.

For conventional types of antennas connect the yellow wire to the antenna lead and the yellow with black tracer and the black wire together to the ground lead.

When a doublet antenna is used connect the yellow wire and the yellow with black tracer wire to the doublet antenna and the solid black wire to the ground lead. (See Fig. 1—Top View, page 2).

ANTENNA:

For the best results an outside antenna approximately 75-100 feet long including the lead-in should be used. It should be erected as high as possible and as far from surrounding objects as practical. Both the antenna and lead-in should be placed at right angles to street car lines and incoming power lines and as far from any electrical apparatus which may be in the vicinity (such as elevator motors) as practical.

MODEL 1173

Alignment, Notes

GOODYEAR SERVICE

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of the multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 minfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS (465 K.C.)

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I. F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view Fig. 3).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

- Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.
- With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.
- With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:

- Adjust broadcast series pad (adjustment number 3) to resonance with oscillator. Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 1.
- Re-set external oscillator to 1400 K.C., move dial pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 3.
- Repeat adjustments "a" and "b" until sensitivity is at its maximum.
- Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser to correct tracking.

SHORT WAVE BAND ALIGNMENT:

5.3 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator

set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

- Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.
- Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle can be tuned in not only at 18.3 on the dial, but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5300 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

- Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.
- Re-check broadcast alignment and if it is found necessary to re-adjust either R.F. or antenna trimmers, repeat the 17 M.C. short wave and 5 M.C. middle wave adjustments.

ANTENNA AND GROUND LEADS:

You will notice three wires coming out of the back of the chassis, — the yellow wire and the yellow with black tracer wire are used for doublet antenna connections. The black wire is the ground connection.

For conventional types of antennas connect the yellow wire to the antenna lead and the yellow with black tracer and the black wire together to the ground lead.

When a doublet antenna is used connect the yellow wire and the yellow with black tracer wire to the doublet antenna and the solid black wire to the ground lead. (See Fig. 1—Top View, page 2).

ANTENNA:

For the best results an outside antenna approximately 75-100 feet long including the lead-in should be used. It should be erected as high as possible and as far from surrounding objects as practical. Both the antenna and lead-in should be placed at right angles to street car lines and incoming power lines and as far from any electrical apparatus which may be in the vicinity (such as elevator motors) as practical.

DESCRIPTION:

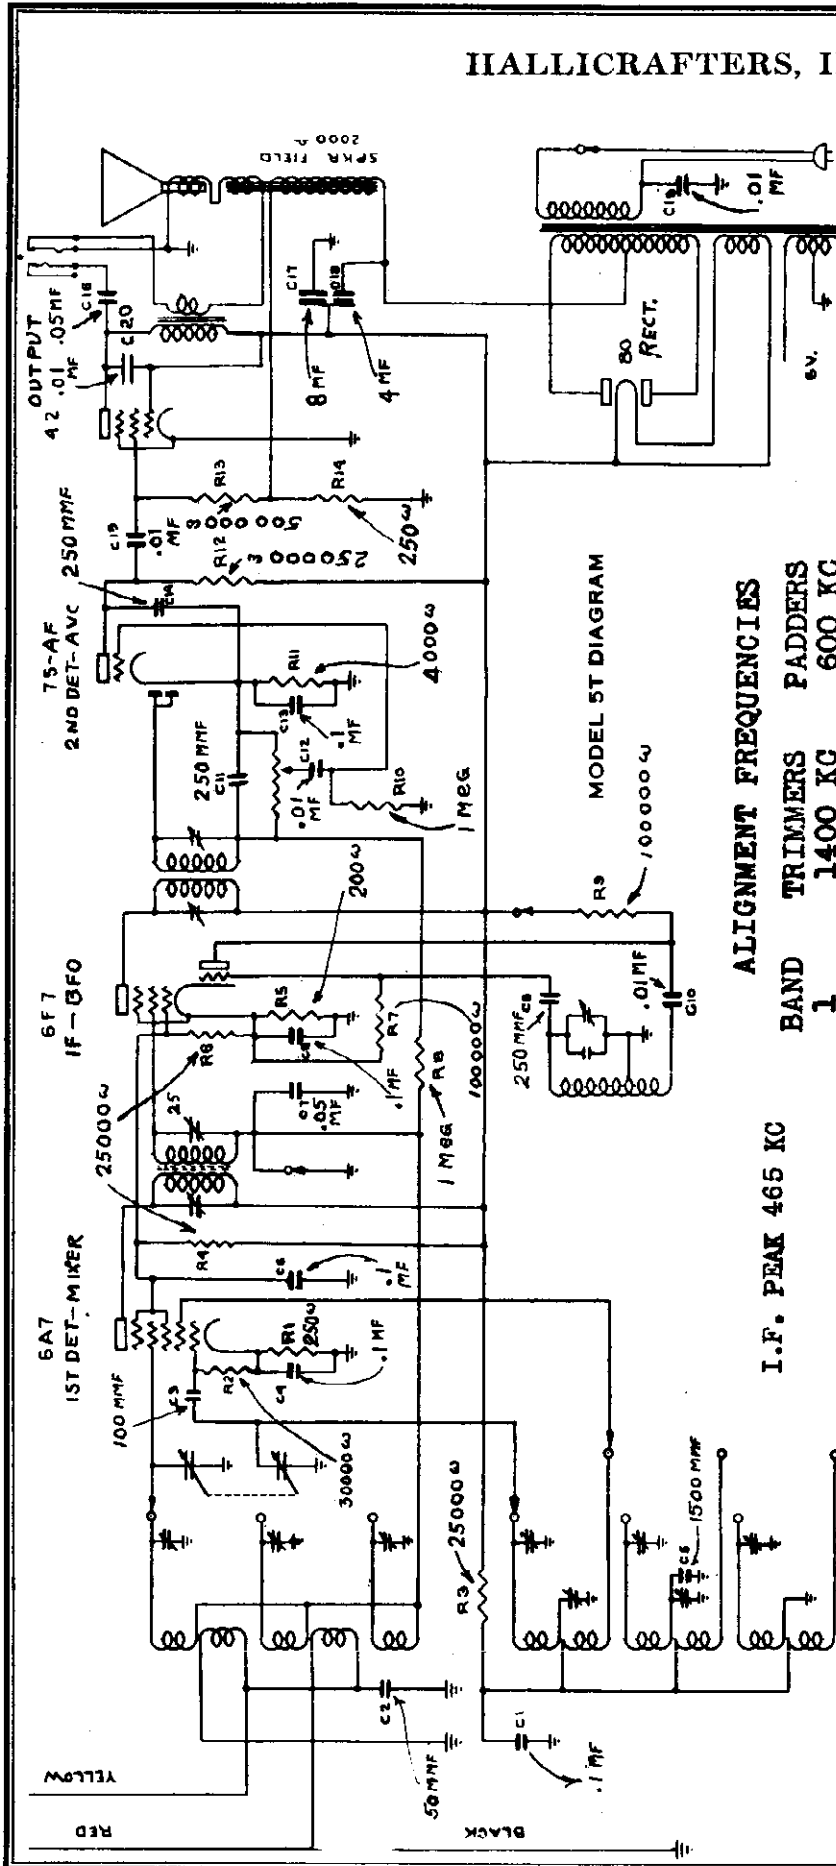

The tube complement of this chassis consists of the following metal and octal base glass tubes which are interchangeable with metal tubes:

- 1—Type 6K7 Remote cut-off pentode R.F. amplifier
- 1—Type 6J7 Pentode first detector
- 1—Type 6C5 Oscillator
- 1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
- 1—Type 6H6 Duplex diode second detector and A.V.C.
- 1—Type 6F5 First audio amplifier
- 1—Type 6F6 Triode driver stage
- 2—Type 6F6 Class AB Output pentodes in push-pull
- 1—Type 5Z3 High vacuum rectifier
- 1—Type 6G5 Cathode Ray Tuning Indicator.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

The 1936 Sky-Buddy receiver is a three band receiver tuning the frequencies as follows:

- No. 1 Band - 1680 KC to 545 KC
- No. 2 Band - 1680 KC to 5.5 MC
- No. 3 Band - 5.5 MC to 16 MC

It includes three sets of antenna coils and three oscillator coils.

 Alignment

HALLICRAFTERS, INC.

MODEL S12, Commercial
 Alignment Sky Rider

**ALIGNMENT FOR MODELS S11 (SUPER-SKY-RIDER 1937)
 and MODEL S15 (SKY CHALLENGER)**

INTERMEDIATE FREQUENCY ALIGNMENT

If the receiver is equipped with a crystal, use the crystal in a separate oscillator.
 If the receiver is used without a crystal set the signal generator at 455 KC before alignment, turn off the AVC, BFO, and Crystal switches. Set the RF and Audio gain controls at maximum. Set crystal phasing condenser for maximum noise level. Do not remove bottom plate from the chassis.
 Remove 6C5 Oscillator tube from socket, and connect the signal generator output directly to grid of 6L7 list detector.
 Adjust all IF transformers for maximum output.

RF ALIGNMENT

Check dial - at maximum capacity of gang condenser the dial should stop so that "0" on the main tuning dial should be opposite "0" on the vernier scale.
 Set band spread condenser at minimum capacity or so that it reads 200 degrees.
 Replace 6C5 oscillator tube and connect signal generator output through 400 ohm resistor to antenna and ground posts on receiver. (Leave Jumper connected.)
 Set dial of receiver to 600 KC of Band #1, and set signal generator to 600 KC. Now adjust .6 MC pad on top of chassis until signal is resonated.
 Reset dial and signal generator to 1100 KC. Adjust 1.1 MC Dec. trimmer condenser beneath the chassis until this signal is properly resonated. Now adjust RF and Detector trimmers for maximum gain. Now reset dial and signal generator to 600 KC and re-pad. It may be necessary to pad and trim at 600 KC and 1100 KC a few times as a change of capacity at one end will affect the other end. Re-check on RF and Detector trimmers and peak for maximum gain.

BAND #2

Follow same procedure as on Band #1 except pad (above chassis) at 1.5 MC. Trim at 2.6 MC

BAND #3

Same procedure as before except pad oscillator at 3 MC. Trim at 6 MC. Hook the gang condenser when making these adjustments.

BAND #4

Pad oscillator at 7 MC. Trim at 14 MC. Hook gang condenser during adjustment

BAND #5

Pad oscillator at 17 MC and Trim at 34 MC. Hook gang condenser as before.

It may be necessary to go through the above procedure several times before maximum performance is secured. A small change at each end of each Band will affect the other end.
 When making adjustments on this receiver back off on RF gain leaving the AF gain at maximum at all times.

Be sure and turn the trimmers all the way in (clockwise) except as noted below, and back off to find the signal. On air-dielectric trimmers, capacity is reduced when turning the screws in a clockwise direction.
 Detector trimmers on Band #4 and #5 should be backed out all the way and screwed clockwise to find the signal. This will assist in eliminating phasing in the wrong direction or side.
 Be sure to check images on Bands #3, #4, and #5. These images will fall approximately 1.0 MC lower in frequency on all Bands.

ALIGNMENT FOR MODEL S12 (COMMERCIAL-SKY-RIDER)

INTERMEDIATE FREQUENCY ALIGNMENT

If the receiver is equipped with a crystal, use the crystal in a separate oscillator. If the receiver is not an S12 model, set the generator for 1600 KC. Before alignment, turn off the AVC, BFO, and Crystal Switches. Set the RF and Audio controls at maximum. Set crystal phasing condenser for maximum noise level. Do not remove the bottom plate from the chassis.
 Remove 6C5 oscillator tube from the chassis, and connect the signal generator output directly to the grid of the 6L7 list detector.
 Adjust all IF transformers for maximum output.

RF ALIGNMENT - BAND #1

Check dial - at maximum capacity of gang condenser the dial should stop so that "0" on the main tuning dial should be opposite "0" on the vernier scale.
 Set Band Spread condenser at minimum capacity or so that it reads 200 degrees.
 Replace 6C5 oscillator tube in receiver, and connect signal generator output through 400 ohm resistance to antenna and ground posts on receiver. (Jumper should remain connected.)
 Set signal generator for 115 KC, put receiver on Band #1 and set dial to a reading of 115 KC.

Adjust the 115 KC pad on top of chassis until signal is resonated.
 NOTE: On Band #1 and #2 it is necessary to adjust detector and RF trimmers each time oscillator trimmer is changed.

Reset dial to 250 KC and reset signal generator to same frequency.
 Adjust 250 KC Dec. trimmer condenser beneath the chassis until the signal is properly resonated. Now adjust RF and detector trimmers for maximum gain. Now reset dial and signal generator to 115 KC and re-pad above chassis.

It may be necessary to pad and trim at 115 KC and 250 KC a few times as a change of capacity at one end will affect the other end. Re-check on RF and the detector trimmers and peak for maximum gain.
 Hook main tuning condenser during the course of these adjustments.

BAND #2

Follow same procedure as on Band #1 except pad (above chassis) at 275 KC and set signal generator at 275 KC. Peak RF and trim at 550 KC. Hook main condenser.

BAND #3

Same procedure as before except pad oscillator at 700 KC, trim at 1400 KC. with signal generator set at 700 KC. Hook main tuning condenser during procedure.

BAND #4

Same procedure as before except pad oscillator at 1.9 MC. with signal generator set at 1.9 MC. Peak RF and detector trimmers for maximum gain. Trim at 3.8 MC.
 Hook main tuning condenser when making the adjustments.

BAND #5

Same procedure as before. Pad oscillator at 5 MC with signal generator set at 5 MC. Adjust RF and detector trimmers for maximum gain, hooking the gang condenser while adjusting. Trim at 10 MC
 It may be necessary to repeat the above adjustments several times before maximum performance is obtained. When making adjustments on this receiver back off on RF gain leaving AF gain at maximum at all times.

Be sure and turn trimmers all the way in (clockwise) (except as noted below) and back out to find the signal. On these air-dielectric trimmers, capacity is reduced in clockwise direction. Check for images on Band #5, 5600 KC lower.

Trimmers

HOWARD RADIO CO.

I.F. = 465 KC.

HOWARD RADIO CO.

Peak oscillator trimmer T5 to 1400 KC from the signal generator.

Peak antenna trimmer T1 to 1400 KC after adjusting oscillator.

Set dial hand to 600 KC and adjust oscillator padding condenser T5 to 600 KC.

IV. MODELS S256 AND S259 WITH A 5.5 TO 15 MC BAND ALIGN AS FOLLOWS:

Tune dial hand to 17 megacycles.

NOTE: FOR ADJUSTMENT AT 17 MEGACYCLES THE OUTPUT FROM THE SIGNAL GENERATOR MUST NOT BE COUPLED DIRECT TO THE ANTENNA LEAD OF THE SET. FOR TRUE ALIGNMENT, SURETCH OUT THE RADIO ANTENNA LEAD IN SUCH A MANNER THAT IT WILL PICK UP THE SO CALLED "WILD" SIGNAL OF 17 MEGACYCLES EMITTING FROM THE GENERATOR. IT IS ALSO IMPORTANT THAT THIS SIGNAL ONLY BE STRONG ENOUGH TO JUST BE HEARD.

When the above set-up is arranged peak oscillator T4 to the 17 megacycle peak signal.

After adjusting the oscillator trimmer, peak the S.W. antenna condenser T2 to 17 megacycles.

NOTE: After adjusting the short wave band at 17 megacycles, the signal generator output to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 MC.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 MC and forth at 16.9 MC.

Reduce signal voltage from generator, go back to 17 MC and slightly correct this last trimmer adjustment.

V. SERVICE NOTES

Seal all trimmers after their final adjustment.

The normal voltage readings of the circuits are shown on the schematic diagram of the set.

In any instance when microphonism is present, first check the dial frame and do not let it or any part of the dial touch the inside of the front panel.

Should the calibrated dial card on Models S-256 and S-259 be moved at any time, be sure and relocate it far enough to the right (when facing the front of the set) otherwise the calibration lines will not be true at various points on the dial.

Be sure that the trimmer settings are made to the true fundamental signal from the generator and not to a harmonic or image frequency.

THE ALIGNMENT PROCEDURE

MODELS 256, 259, S256, S259 AND 5B

The following alignment instructions are given with the assumption that the service station has a signal generator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected, in the output stage to indicate resonance. This can be an 0 to 5 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the power tube in series with an 8 Mfd. paper condenser.

I. THE I. F. STAGES

The intermediate frequency stages are aligned in the usual manner on Models 256, S259 and 5B by feeding 465 KC into the grid of the mixer tube after removing grid cap, placing a series resistor of 500,000 ohms from tube grid to the cap and a series condenser from the tube grid to the hot lead from the signal generator. NOTE WITH MODELS 256 AND S256 LEAVE GRID CAP ON THE MIXER TUBE, TURN BAND SWITCH TO BROADCAST BAND POSITION AND VARIABLE CONDENSER ALL THE WAY OUT TO MINIMUM CAPACITY.

The sensitivity of the I. F. system alone for Models 256, S256, 259 and S259 will be about 25 to 50 Microvolts for a 50 Milliwatt output, and about 125 Microvolts for Model 5B.

The two trimmers in each of the I. F. Cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set.

Always use as low an output as possible from the signal generator when making the various adjustments.

II. THE S. W. BAND 2 TO 6 MEGACYCLES

SEE SECTION IV FOR MODELS WITH A 5.5 TO 15 MC BAND

First check the position of the dial hand by rotating the condenser plates to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position, remove dial glass to get at the screw holding the hand.

With the dial hand set to 6 megacycles and the band switch in the short wave position (all the way to the right) see Figure 1 and peak trimmer T4 of the oscillator circuit to 6 megacycles.

After adjustment of the oscillator trimmer, peak trimmer T5 to 6 megacycles from the generator.

III. THE BROADCAST BAND

Turn wave band switch all the way to left and dial hand set to 1400 KC (the top scale). The signal generator may be coupled direct to the antenna lead on this band, through a standard 200 MAFD condenser.

MODELS 68 Revised
266,268
Alignment

HOWARD RADIO CO.

NOTE: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response, the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists, then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 M.C.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

IV. THE ALIGNMENT OF THE BROADCAST BAND

1. Set Band Switch to the 550-1700 K.C. band, and the hand to 1400 K.C.
2. Peak oscillator trimmer C-38 to 1400 K.C., then the R.F. Trimmer C-4 and the antenna stage trimmer C-13 on the variable condenser to 1400 K.C.
3. Rotate dial hand to 550 K.C. and adjust padding condenser C-37 to 550 K.C.
4. Re-check dial at 1400 K.C. as mentioned in (1) and (2).
5. Points in the middle of the dial may be checked and if necessary the plates of the oscillator section of the variable condenser (back section) may be bent for alignment.

V. NOTES

1. Seal all trimmers after their final adjustment.
2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.
3. The normal voltage readings at the sockets are given in a separate chart on the following pages.
4. It is advisable to check the position of the tuning eye tube to make certain that it is not pushed against the inside of the dial card. With the adjustment screw on the bracket, allow a small amount of clearance between the end of the tube and the dial to avoid any possibility of the heat from the tube affecting the dial card.

THE ALIGNMENT PROCEDURE

The following alignment instructions are given with the assumption that the Service Station has a signal generator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be an 0 to 3 Volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the power tube in series with an 8 Mfd. paper condenser.

I. THE I.F. STAGES

The intermediate frequency stages are aligned in the usual manner by feeding 465 K.C. into the grid of the mixer tube 6A7.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers Nos. C-26, 27, 28, 29 on Figure 2.

Always use as low an output as possible from the signal generator when making the various adjustments.

The sensitivity of the I.F. system alone will be found to be between 15 and 20 Microvolts.

II. ALIGNMENT OF THE SHORT WAVE BAND 5.5 TO 18 M.C.

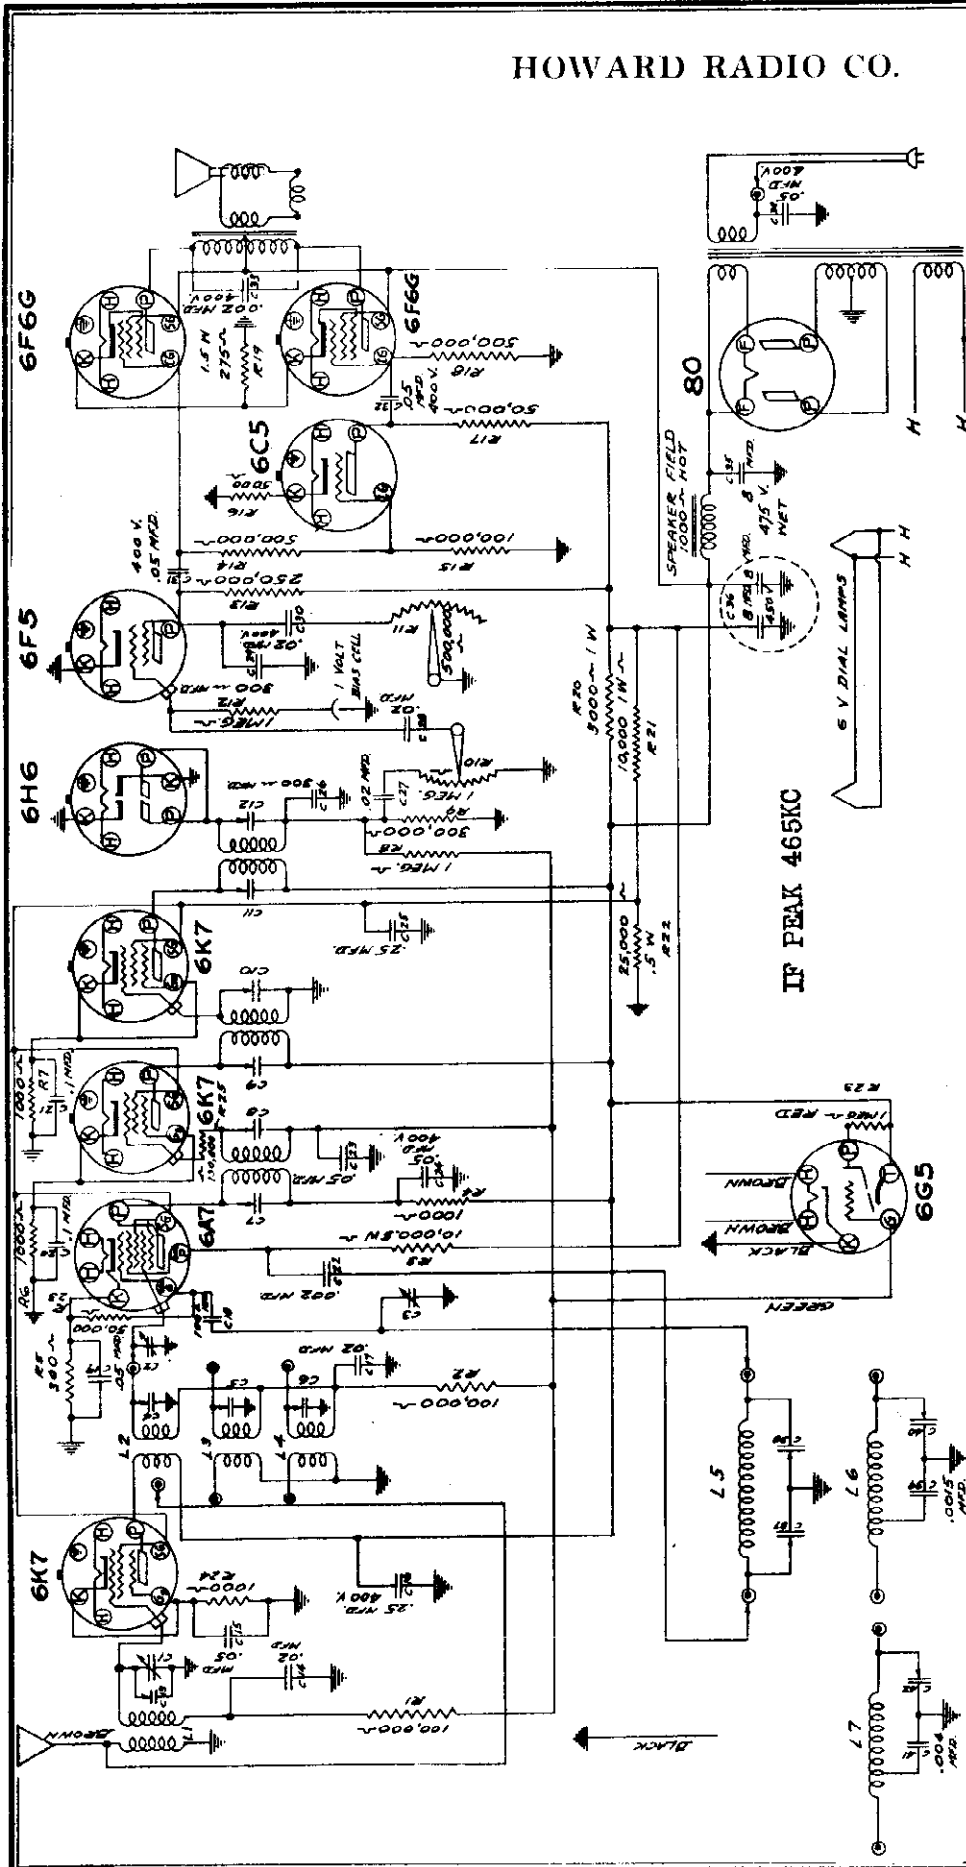

First check the position of the dial hand by rotating the variable condenser to full capacity. The hand then should be in line with the lines that divide the dial in half. If the hand is off position it can be lined up by loosening the center screw.

1. Turn band switch all the way to the right for the 5.5 to 18 M.C. Band (Yellow), and set dial hand to 17 M.C.
2. Refer to Figure 3 and with a 17 M.C. signal from the generator, peak oscillator, trimmer condenser C-42 to 17 M.C.
3. Adjust trimmer C-6 of the antenna circuit to 17 M.C. after the above mentioned oscillator trimmer has been set.

III. ALIGNMENT OF SHORT WAVE BAND 1.7 TO 5.5 M.C.

1. With the band switch in the middle position, (Blue) and the dial hand set to 5 M.C., peak trimmer C-40 of the oscillator circuit to 5 M.C.
2. Adjust antenna stage trimmer C-5 to 5 M.C. after the above oscillator trimmer has been set.

FIG. 1

FIG. 3

HOWARD RADIO CO.

MODEL S 118, 218
Alignment

NOTE: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response, the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists, then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 M.C.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

IV. THE ALIGNMENT OF THE BROADCAST BAND

1. Set Band Switch to the 550-1700 K.C. band, and the hand to 1400 K.C.
2. Peak oscillator trimmer C-38 to 1400 K.C., then the R.F. Trimmer C-4 and the antenna stage trimmer C-13 on the variable condenser to 1400 K.C.
3. Rotate dial hand to 600 K.C. and adjust padding condenser C-37 to 600 K.C.
4. Re-Check dial at 1400 K.C. as mentioned in (1) and (2).
5. Points in the middle of the dial may be checked and if necessary the plates of the oscillator section of the variable condenser (back section) may be bent for alignment.

V. NOTES

1. With certain Model 118's a 40,000 ohm resistor will be found located from oscillator grid to cathode of the 6A7 in place of 50,000.
2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.
3. The normal voltage readings at the sockets are given in a separate chart on the following pages.
4. It is advisable to check the position of the tuning eye tube to make certain that it is not pushed against the inside of the dial card. With the adjustment screw on the bracket, allow a small amount of clearance between the end of the tube and the dial to avoid any possibility of the heat from the tube affecting the dial card.

THE ALIGNMENT PROCEDURE

The following alignment instructions are given with the assumption that the Service Station has a signal generator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be an 0 to 3 Volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the power tube in series with an 8 Mfd. paper condenser.

I. THE I.F. STAGES

The intermediate frequency stages are aligned in the usual manner by feeding 465 K.C. into the grid of the mixer tube 6A7. Remove grid cap, place series resistor of 500,000 ohms from the tube grid to the cap and a series condenser from the tube grid to the "hot" lead from the signal generator.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers Nos. C-7, C-8, C-9, C-10, C-11 and C-12 (See Fig. 1)

Always use as low an output as possible from the signal generator when making the various adjustments.

The sensitivity of the I.F. system alone will be found to be between 15 and 20 Microvolts.

II. ALIGNMENT OF THE SHORT WAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the variable condenser to full capacity. The hand then should be in line with the lines that divide the dial in half. If the hand is off position it can be lined up by loosening the center screw.

1. Turn band switch all the way to the right for the 5.5 to 18 M.C. Band (Yellow), and set dial hand to 17 M.C.
2. Refer to Figure 3 and with a 17 M.C. signal from the generator, peak oscillator, trimmer condenser C-42 to 17 M.C.
3. Adjust trimmer C-6 of the antenna circuit to 17 M.C. after the above mentioned oscillator trimmer has been set. Watch this adjustment that it will not "drag" the oscillator.

III. ALIGNMENT OF SHORT WAVE BAND 1.7 to 5.5 M.C.

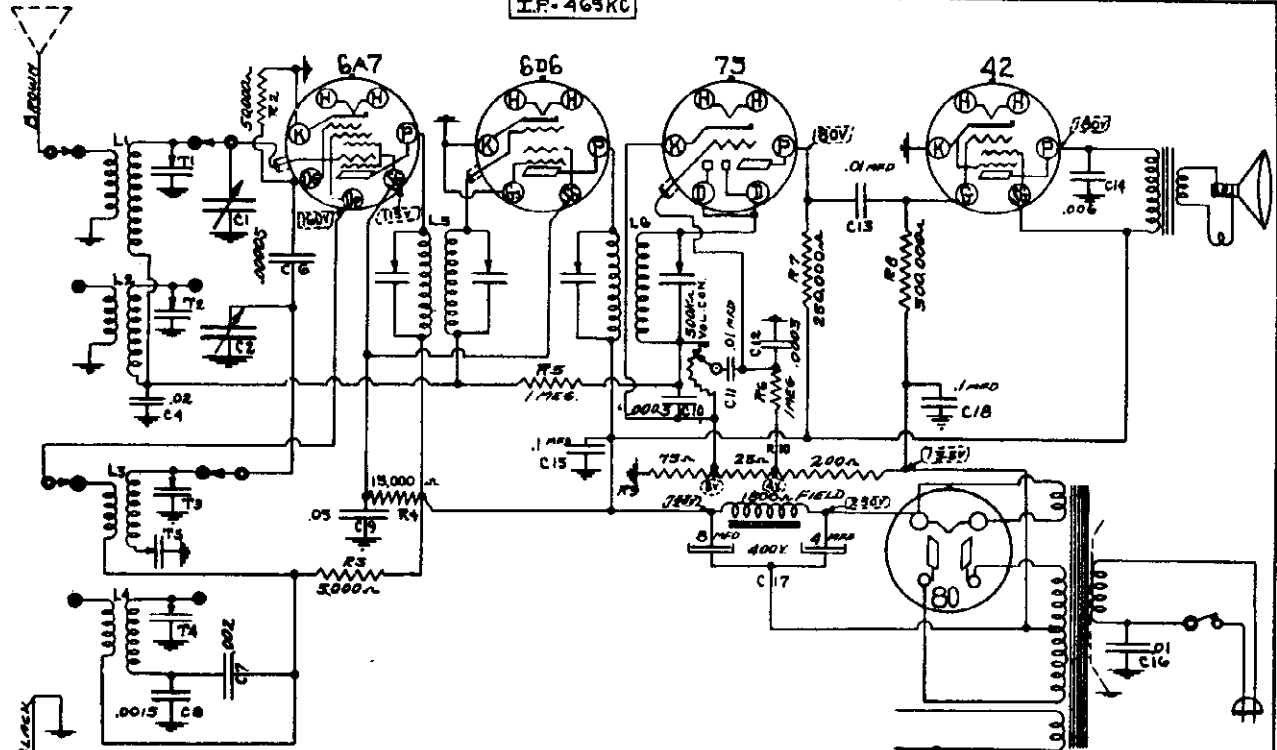

1. With the band switch in the middle position, (Blue) and the dial hand set to 5 M.C., peak trimmer C-40 of the oscillator circuit to 5 M.C.
2. Adjust Antenna Stage trimmer C-5 to 5 M.C. after the above oscillator trimmer has been set.

HOWARD RADIO CO.

Alignment

Peak oscillator trimmer C-10 to 5 M.C. from test oscillator. And Ant. coil trimmer C-6 to same frequency.

NOTE: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 M.C.

Increase oscillator signal by "opening up" the alternator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

IV THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400 KC (the top scale).

2. Peak oscillator trimmer C-9 to 1400 KC, the Antenna preselector C-12 (variable condenser trimmer) to 1400 KC, and trimmer C-5 to 1400 KC.

3. Set dial hand to 550 KC and adjust oscillator padding condenser C-8 to 550 KC.

4. Recheck dial at 1400 KC as in number (1) and (2).

5. Points in the middle of the dial may be checked and if necessary the plates of the front section of variable condenser may be bent for alignment.

V NOTES.

1. Seal all trimmers after their final adjustment.
2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.
3. Refer to the schematic for the voltages at the tube sockets.

THE ALIGNMENT PROCEDURE

The following alignment instructions are given with the assumption that the service station has an oscillator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be 0 to 3 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the 42 power tube in series with an 8 MFD paper condenser.

I THE I. F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers number C1, C2, C3, C4. (See pictorial diagram).

The sensitivity of the I.F. stages will be 40 microvolts or better.

Always use as low an output as possible from the test oscillator in making the various adjustments.

II ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the condenser shaft to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can be easily lined up by loosening the set screw behind the dial card in the drive hub.

1. Set the test oscillator to 17 megacycles.

2. Turn wave band switch all the way to right for highest S.W. band, and set dial hand to 17 M.C.

3. Peak trimmer condenser C-11 of the oscillator coil (See pictorial 6-2) to resonance with 17 M.C. fed into antenna.

4. Peak Ant. coil trimmer C-7 at same setting to 17 M.C.

III SHORT WAVE BAND 1.7 TO 5.5 M.C.

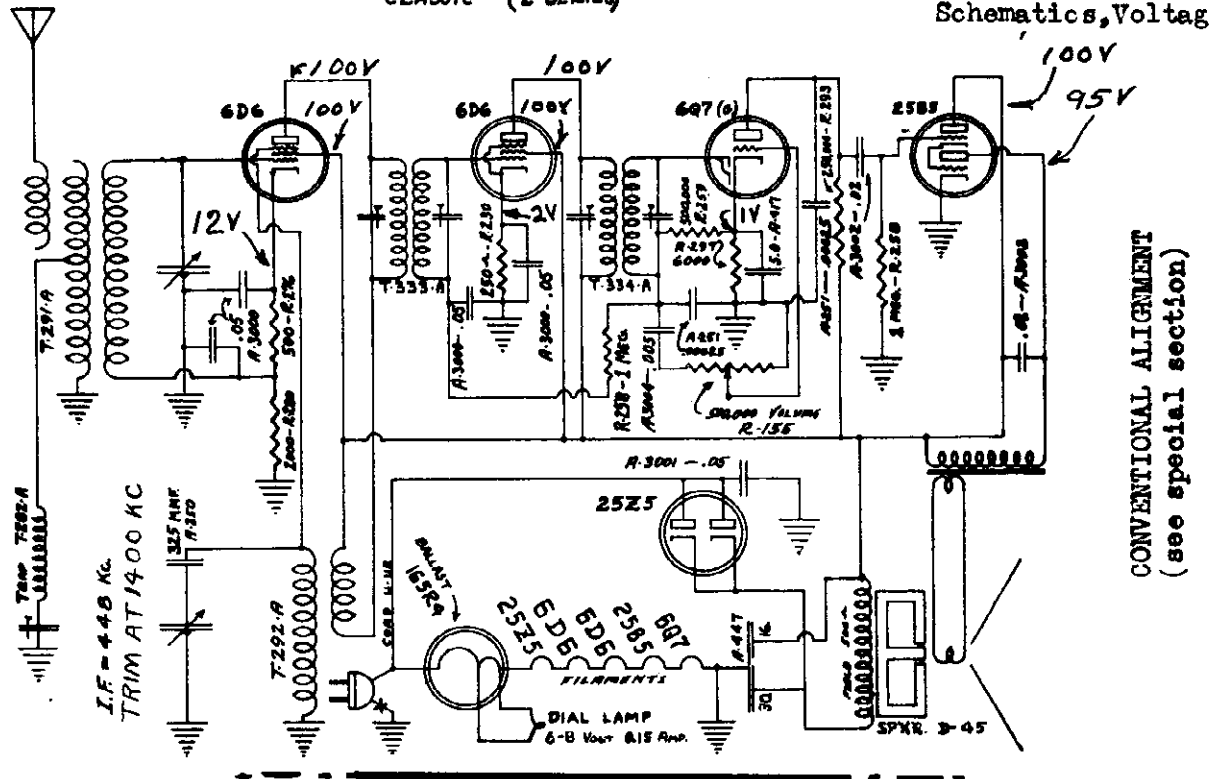

1. Turn wave switch to middle position.

2. Set dial hand to 5 megacycles on the 1.7 to 5.5 M.C. inner scale.

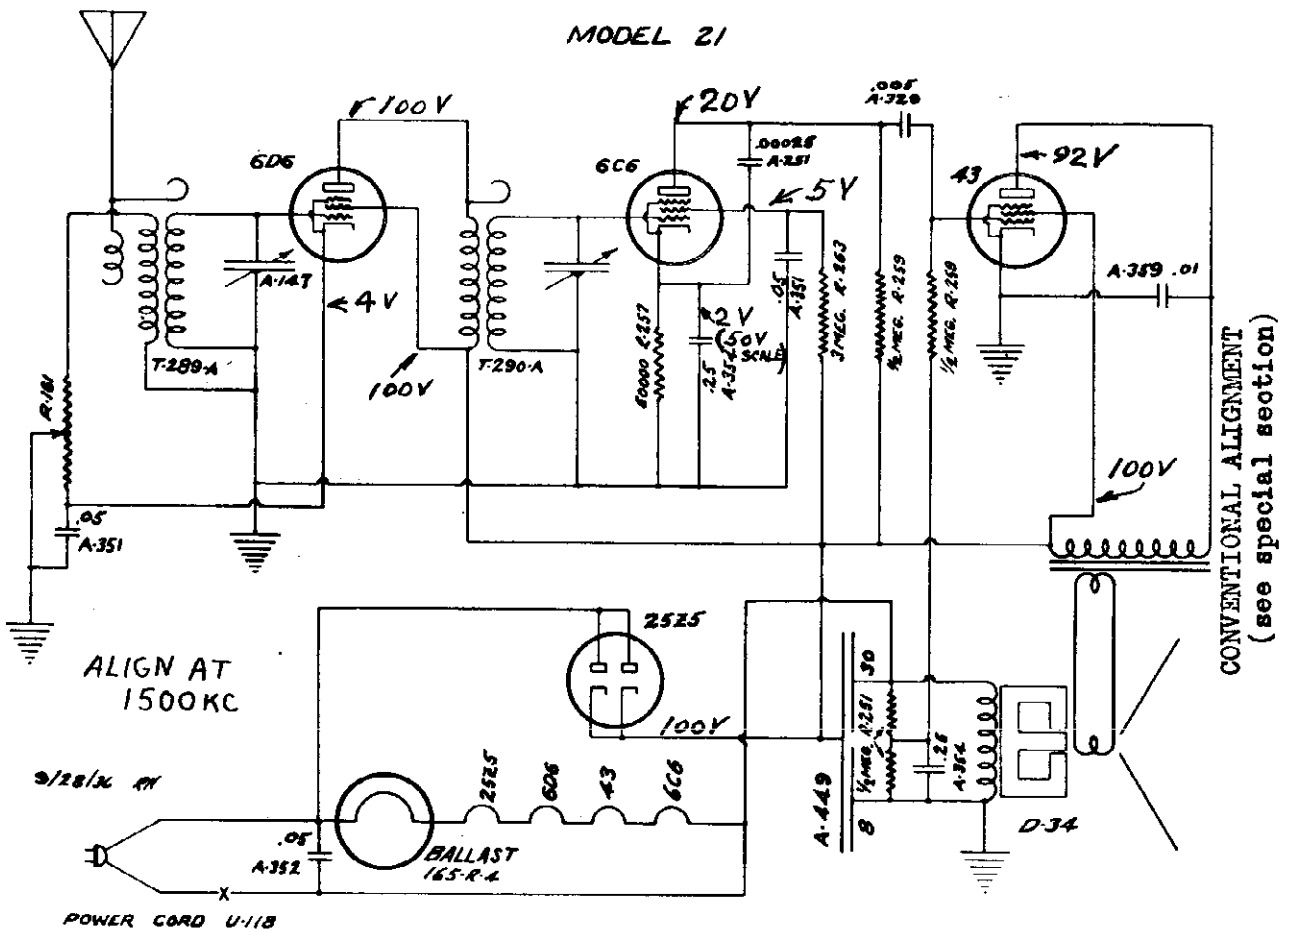

INTERNATIONAL RADIO CORP.

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc. The oscillator frequency is 448 kilocycles higher than the signal frequency. Aligning should be done on the following frequencies: 1,400, 1,000, and 600 Kc.

INTERMEDIATES: To align the I.F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I.F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I.F. transformer. If adjustments are not made accurately, selectivity will be poor and I.F. oscillation may result. Finally, adjust the trimmer on the tuned wave trap for minimum meter reading.

BROADCAST BAND: Turn the dial to 1400 Kc. and feed a *very weak* 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the Broadcast oscillator trimmer for maximum reading. Then peak Broadcast antenna trimmer to this oscillator setting.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

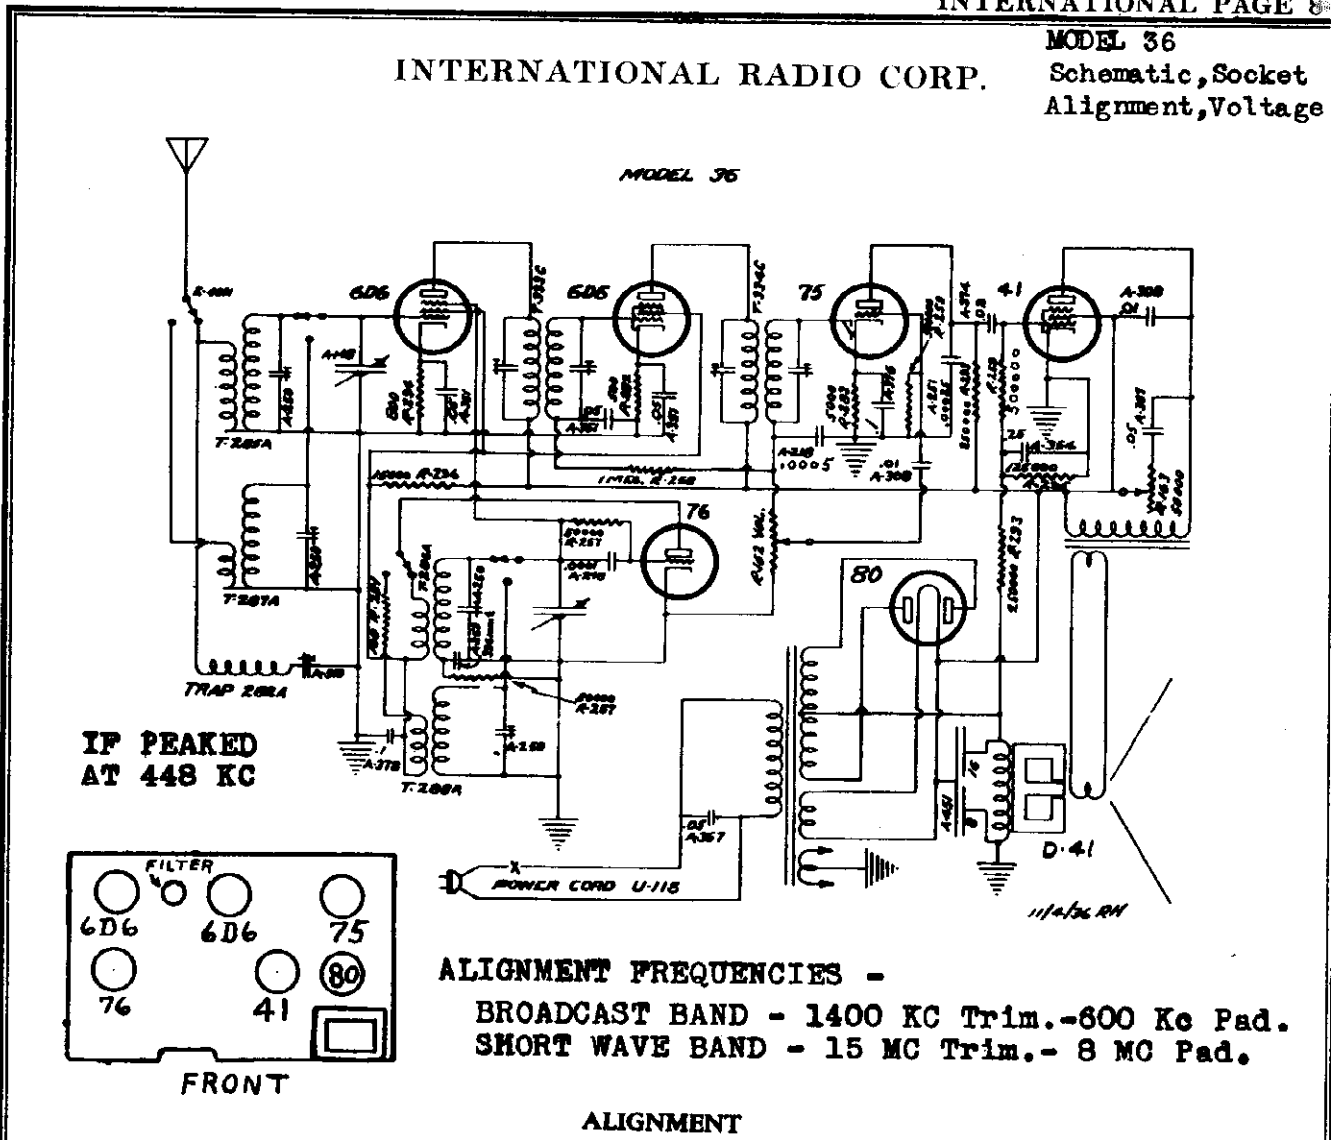

AVERAGE SOCKET VOLTAGES

Tube	Position	Ek	Eg ₁	Eg ₂	Ep
6D6	Det-Osc.	18	0	110	110
6D6	I.F.	1.7*	1.7*	110	180

INTERNATIONAL RADIO CORP.

MODEL 36
Schematic, Socket
Alignment, Voltage

The four trimmers on the bottom of the chassis are, reading from the side of the chassis by switch toward the center, Short wave antenna, Broadcast antenna, Short wave oscillator and Broadcast oscillator.

INTERMEDIATES: To align the I.F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I.F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I.F. transformer. If adjustments are not made accurately, selectivity will be poor and I.F. oscillation may result. Finally, adjust the trimmer on the tuned wave trap for minimum meter reading.

BROADCAST BAND: Place the band change switch on Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the Broadcast oscillator trimmer for maximum reading. Then peak Broadcast antenna trimmer to this oscillator setting.

Turn dial and signal generator to 600 Kc. and rock the padder into correct adjustment. This is accomplished by very slowly adjusting the padder condenser and at the same time turning the dial slightly back and forth across 600 Kc. until an adjustment is obtained producing maximum output. Go back to 1400 Kc. and readjust the oscillator trimmer slightly if necessary. Then recheck padder at 600 Kc.

SHORT WAVE BAND: Place the band change switch on the Short Wave position. Turn the dial to 15 megacycles and feed a very weak 15 megacycle modulated signal from your signal generator to the antenna. Adjust the S.W. oscillator trimmer for maximum reading on the output meter. This trimmer should not be touched again when checking alignment on other frequencies. Then peak S.W. antenna trimmer to this oscillator setting.

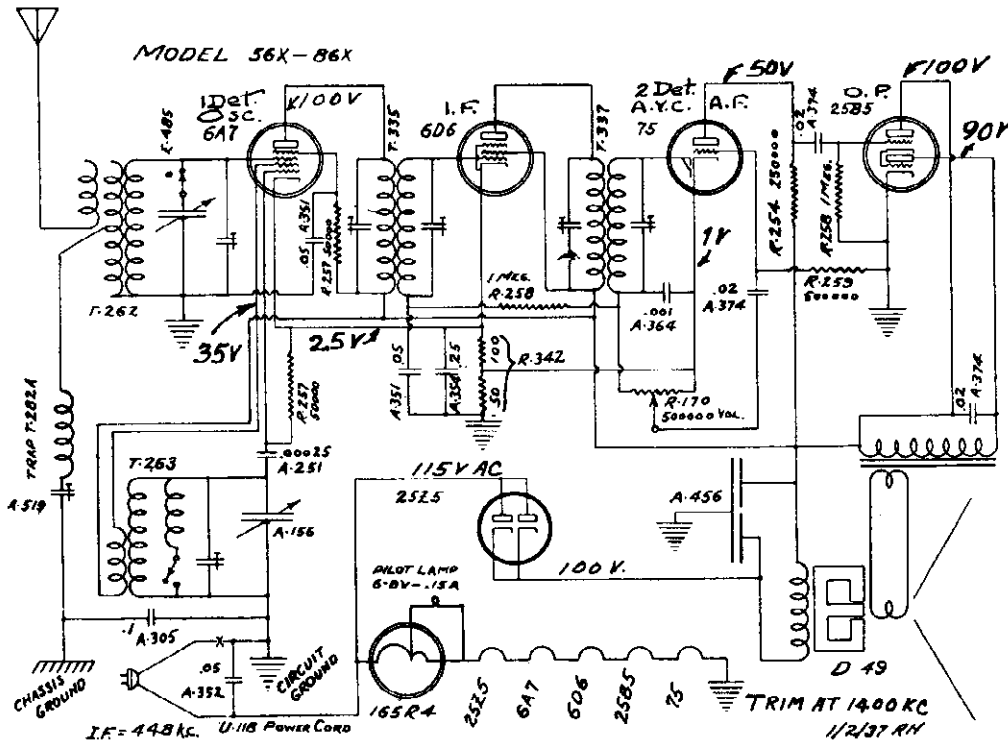

Instead of bending condenser plates at 8 megacycles alignment is accomplished by spreading or crowding turns on the S.W. detector coil. If much crowding or spreading is necessary it is advisable to go back and recheck at 15 megacycles.

MODEL Electone Piano
Service Notes

KRAKAUER BROS.

AMPLIFIER CIRCUITS:

The output transformer is especially designed and if it is damaged, an exact replacement is necessary.

The tone control is subject to wide variations according to individual requirements. Some forms depend on the cathode by-pass for control; therefore, replace this component with exact value.

Use only glass tubes in the input, as the leakage is less, and only glass tubes in the output, because of the possibility of a short to the shell.

NOISE ELIMINATION:

First suspect dirt on the pick-up screws. These are insulated with lacquer, but this is not perfect. Clean with a vacuum-cleaner with blower attachment, which should be run for a few minutes so that the hose will be free from dirt. A thin strip of paper can be worked between the strings and the pick-up screws to remove stubborn particles of dirt.

Moisture may get into the wooden strip supporting the pick-up screws. This can be dried by placing in the bottom of the piano a $\frac{1}{2}$ pint fruit jar which is $\frac{1}{3}$ filled with calcium chloride. This should be renewed when it disintegrates. When the strip is dry it should be oiled with Nujol.

Another source of noise may be leakage in the input group (the two 10-megohm resistors and the .1-mf condenser). Replace with the best components obtainable. In severe climates place these three components in a small cardboard pill-box and fill it with paraffine wax, bringing out the leads so they can be readily connected to their proper points.

HUM:

Hum may be due to trouble in the filters, unmatched output tubes, or a poor bias rectifier, if trouble is confined to the amplifier.

Electrostatic pick-up to screws is shielded by the back-board of the piano. This board must make good contact with the ground clamps. If proper contact can not be established, cover the back-board with tin-foil shellaced in place and grounded.

REGULATING PICK-UP SCREWS:

This must be done with the help of a professional piano tuner who must be a tone regulator. The tuner should tone regulate the piano very soft, paying attention to evenness of tone and not evenness of volume. Then he can strike the notes, telling the serviceman at the rear of the piano, if the pick-up screws need adjustment. Turn screws to right to make louder -- to the left to make softer. Take care that screws are not turned too far to the right, so that the strings will touch screw when a very hard blow is struck on the key.

These screws should ordinarily need no attention during the life of the piano. Only in case of buckling of the mechanism or tampering need these be touched.

SETTING MASTER LEVEL CONTROL:

The striking of the hammer on the strings sets up tremendous transients in the electrical circuit which last a small fraction of a second. These tend to overload the amplifier and when the average output of the amplifier is 3 or 4 watts, the transients may be of the order of several hundred watts. Accordingly, a 40-watt amplifier is used for low average power. Do not set the screw-driver type volume control too high. The instrument is not supposed to sound much louder than an ordinary acoustic piano.

Overload causes rattling similar to speaker cone rattles. Do not blame the speaker until you are sure.

SWELL PEDAL ADJUSTMENT:

The mechanical connection from the swell pedal to its control should be set so that with the pedal completely depressed, the sound from the speaker is just not noticeable.

NOTE:

Special parts and further service information may be obtained from Krakauer Brothers, 191 Cypress Ave., New York City.

NOTE:
1. DOTTED LINES DENOTE SHIELDING.
2. PARTS UNDER OUR PATENT RELATIVE TO THIS SET.
3. NUMBERS SHOWN WITH PREFIX "M" ARE COMPLETE ASSEMBLIES.
4. I.P. = 465 K.C.

INTERMEDIATE ALIGNMENT: Only when an intermediate transformer has become defective due to an open or burned out winding should it be necessary to readjust the intermediate transformer. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device. To align the intermediate transformer:

1. Connect the high side of the oscillator output to the control grid of the No. 32 Modulator tube. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the intermediate transformer trimmer screws up and down until maximum reading is obtained on the output meter. Then adjust the other trimmer screw in the same manner.
4. The second I.P. transformer should next be adjusted in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

To align the variable condenser:

1. Connect the high output side of the oscillator to the set antenna lead and the ground side of the oscillator to the chassis.
2. Tune the receiver to 1400 kilocycles on the dial and set the oscillator to this frequency.
3. Adjust the variable condenser trimmer screws for maximum output reading.
4. Tune the set to approximately 600 kilocycles on the dial and adjust the oscillator frequency to 600 kilocycles. Adjust the padding condenser located on the rear of the chassis adjacent to the antenna and ground leads and accessible through the hole in the chassis for maximum output reading.

When making this adjustment be sure to rock the variable condenser slightly to the right and left to enter the position where the greatest output reading is obtained.

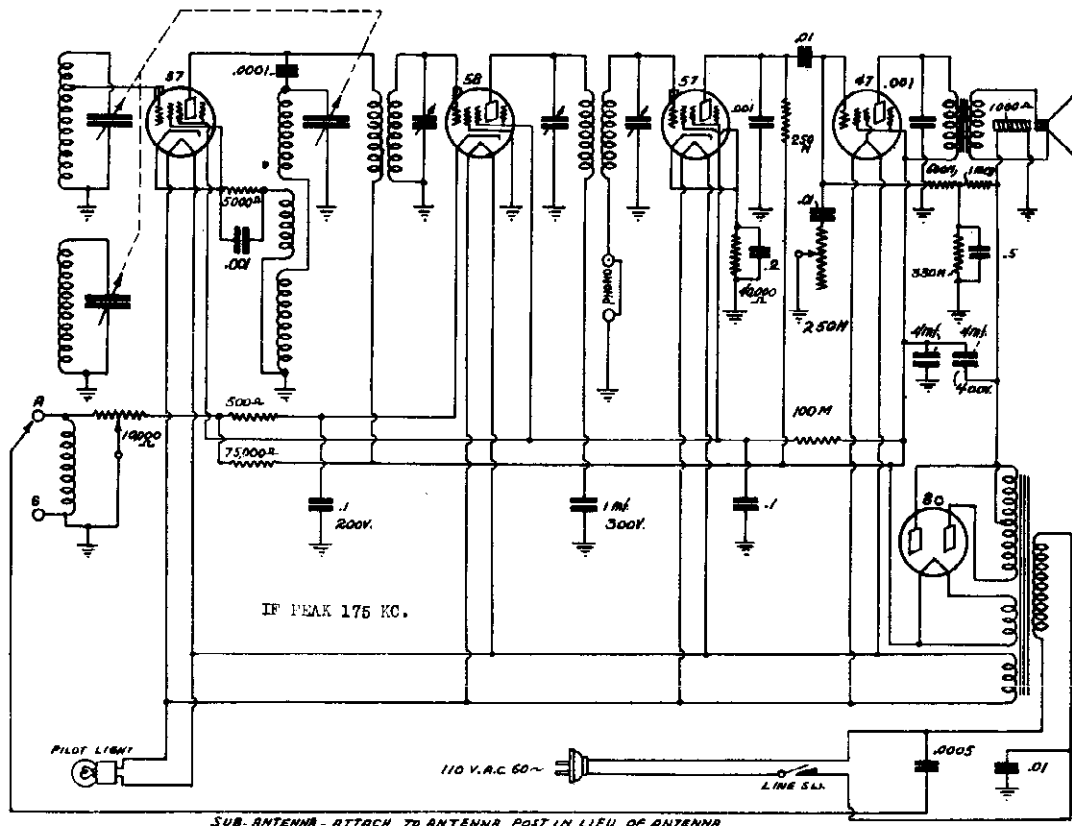

These prices are subject to change without notice.

Notes

LAFAYETTE RADIO MFG. CO.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch should be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the slide return circuit at the volume control. This is done by removing the wire connecting condenser C47 to the wiper R15, R19 and R22, at the terminal strip located near the back of the planetary drive. Cut this wire to correct length and solder it to the proper terminal on the phono switch—See Fig. 7, keeping the wire close to the back of the chassis base.

A wire is then connected from the lug on the above mentioned terminal strip to which C47 was connected, to the correct terminal on the phono switch—See Fig. 7. This wire should be brought directly to the back of the chassis at a point close to the phono jack pin tip nearest the channel provided for a chassis mounting bolt, and then routed over to the switch.

Completes the other connections as illustrated in Fig. 7.

It will be necessary to re-route the AC line cord away from the 6C5 1/2 audio grid lead by running it between the volume control and the filter choke and then straight back to the hose provided for it in the chassis base.

If a hum is heard when the phono pickup is touched, reverse the two pickup leads.

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver in the fact that a different antenna transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment
Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A16, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the wiper of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to prevent the trimmer adequately in replacing a trimmer. Be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft.

If the nut on the back end of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back of this nut out, or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and gears to see if they are turning properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust at the range frequency. This can be checked as follows: Let us say the signal generator is 6000 KC. The signal will then indicate 6000 KC on the dial of the radio. The image signal, which is weaker, will be heard at 1900 low 914 KC or 0383 KC. It may be necessary to increase the input signal to hear the image.

5000 KC Adjustment
Set the signal generator for 5000 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C18) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment
Set the signal generator for 1000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd intermediate Range C trimmer (C7 and C10) and antenna Range C trimmer (C5) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment
Set the signal generator for 1800 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

18,300 KC Adjustment
Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment
Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd intermediate Range D trimmer (C8 and C9) and antenna Range D trimmer (C1) to maximum.

When adjusting the 2nd intermediate Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

I. F. Adjustment

Set the signal generator for a signal of 416 KC. Connect the output of the signal generator through a 100 ohm resistor to the grid of the detector.

Connect the ground lead of the receiver to the ground point of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the leveling of action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment
Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 ohm resistor to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment
Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

In test using pointer, loosen the screw of the large pointer and set the pointer at the 1500 KC mark on the standard wave band scale. Realign the screw.

In sets using the moving beam of light, there is a drum by means of a screw. Loosen the screw and move the light assembly until it is at the 1500 KC mark on the dial. Realign the screw.

Adjust the 1st and 2nd intermediate Range B trimmer (C3 and C11), and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment
Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

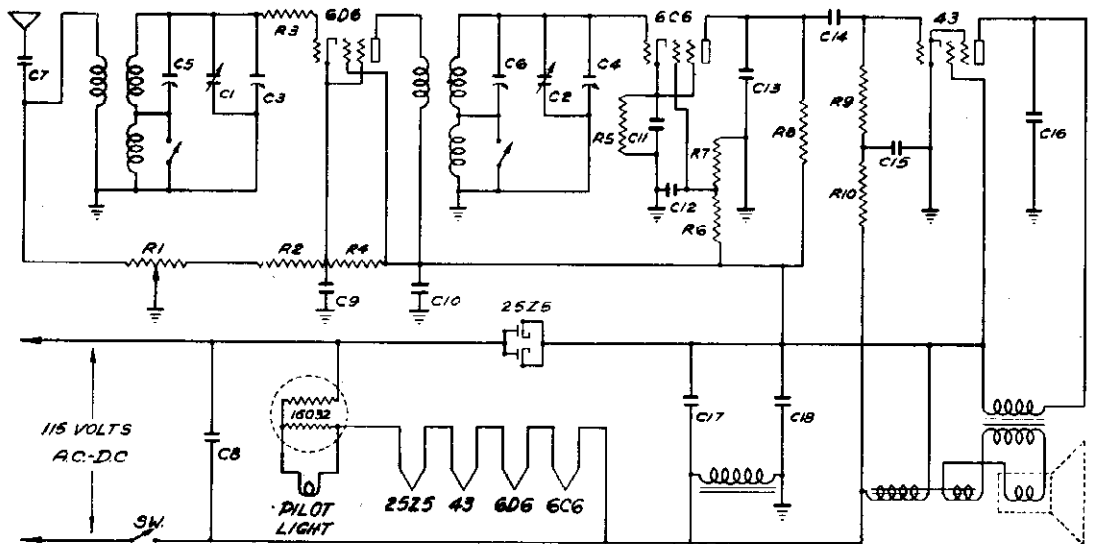

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

MODEL 50
Schematic, Socket
Trimmers, Voltage
Alignment, Part

ALIGNMENT PROCEDURE—Correct alignment is of extreme importance. Your receiver is properly aligned at the factory and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected.

In order to properly realign the receiver, the following equipment is necessary.

1. A signal generator which will provide an accurately calibrated signal at any frequency from 540 to 4000 kilocycles. The generator should have a modulated and adjustable signal output.
2. An output audio voltmeter to be connected across the moving coil of the speaker. This meter should be capable of providing a readable deflection for output levels of 1/2 volt, to avoid the effects of overload.
3. One screw driver; one .25 Mfd. 600 volt condenser; one 100 Mmf. mica condenser.

BROADCAST BAND 540 TO 1550 KILOCYCLES

1. Connect output meter across loud speaker voice coil.
2. Connect ground or low potential terminal of signal generator to receiver chassis through a .25 Mfd. 600 volt condenser.
3. Connect antenna or high potential terminal of signal generator through a 100 Mmf. mica condenser to antenna lead from the receiver.
4. Adjust signal generator to 1400 kilocycles and 5000 microvolts output.
5. Adjust receiver range indicator to broadcast or "B" band and pointer to 1400 kilocycles.
6. Adjust trimmers C3 and C4 until maximum output is obtained and reduce volume level with volume control to approximately 0.5 volt. Repeat until C3 and C4 cannot be adjusted to give greater output.
7. Turn volume control to clockwise or most sensitive position; reduce output from signal generator; retune receiver and check sensitivity.
8. Check sensitivity at 1000 kilocycles and 550 kilocycles.

POLICE BAND 1550 to 4000 KILOCYCLES

1. Adjust signal generator to 4000 kilocycles.
2. Adjust receiver range indicator to police or "P" band and pointer to 4000 kilocycles.
3. Turn receiver volume control to maximum or extreme clockwise position, and increase signal generator output until a signal is heard.
4. Adjust trimmers C5 and C6 until maximum output is obtained and reduce output from signal generator until receiver output is approximately 0.5 volt. Repeat until C5 and C6 cannot be adjusted to give greater output.
5. Check sensitivity at 2400 kilocycles and 1600 kilocycles.
6. Sensitivity at 1600 kilocycles may be adjusted by moving position of lead from wave switch to chassis.

POWER LINE VOLTAGE

The model 620 is designed to operate on 110-115 volts, 50-60 cycles a.c. Serious damage may result if the set is connected to a power supply other than that shown above.

POWER LINE VOLTAGE—The model 60 is designed to operate on 105 to 125 volts, 50-60 cycles a.c. or d.c. Serious damage may result if the set is connected to a power supply other than that shown above. If there is any doubt in your mind, do not plug the set in until you first determine the voltage and cycles from your power supply company.

IF THE RECEIVER IS CONNECTED TO A D.C. SUPPLY FOR TWO MINUTES AND NO SIGNAL IS HEARD, REVERSE THE LINE PLUG.

DIAL LIGHTS—There are two No. 44 Mazda bayonet base dial lights in your receiver. It is not considered advisable to operate the receiver when either of the dial lights are defective as this may injure the ballast tube.

MODEL 60

MODEL 620

In order to properly realign the receiver, the following equipment is necessary.

1. A signal generator which will provide an accurately calibrated signal at any frequency from 400 to 7500 kilocycles. The generator should have a modulated and adjustable signal output.
2. An output audio voltmeter to be connected across the moving coil of the speaker. This meter should be of providing a readable deflection for output levels of 1/2 volt, to avoid the effects of overload.
3. One screw driver; one .25 Mfd. 600 volts condenser; one 200 Mmfd. mica condenser and one 400 ohm resistor.

I. F. SYSTEM

Apply 456 k.c. signal to the grid of 6A8G tube through a tubular condenser on the order of 1 Mfd. Make certain that the wave change switch is in the broadcast position fully counter-clockwise. Turn variable condenser until it is engaged completely.

Referring to figure two which is the trimming diagram: adjust the I. F. capacities in the following order for maximum signal; C6, C5, C3, and C4. Of course to begin with, a very strong signal may be necessary on the input to "find" the preliminary adjustments. As alignment is approached, it is advisable to reduce the generator signal to minimum satisfactory value to prevent the possibility of misalignment due to A.V.C. action. When the I. F. system has been adjusted, it will be found highly advisable to make all adjustments approach the resonance condition by starting at too high a capacity on the trimmer and working to a smaller value to give maximum output. In other words, having all trimmers down tight, unscrew them and bring the adjustment to a point of resonance. This should be done twice with C4. The general idea being to adjust C4 until the capacity has passed through resonance and has become too small. This is merely to indicate the maximum reading position. Return the capacity to an excess value again and gradually reduce it until it reaches its maximum tuning point.

SHORT WAVE BAND

In all cases the ground side of the generator should be connected to the ground on the chassis of the receiver through a .1 Mfd. or larger tubular paper condenser. Apply a 7.2 m.c. signal through a 400 ohm resistance dummy antenna to the terminal strip where the antenna hank connects. Turn the wave change switch in the clockwise direction. Turn the variable condenser until it is completely disengaged. Unscrew trimmer C7 to a minimum capacity. Slowly turn the screw so that trimmer capacity increases until the signal is heard. Adjust C8 until the response is maximum. It may be necessary here to "rock" the variable condenser slightly with the adjustment of C8. The short wave antenna circuit range is now set. Adjust variable condenser until the dial indicator points to 6 m.c. Turn trimmer C7 until signal comes in and reaches maximum. This means that the two circuits are absolutely aligned at this point. Inasmuch as a fixed padder is utilized and comes accurately matched, the two circuits should remain correctly aligned over entire band. It is considered advisable to check this at 4.25 m.c. and 2.4 m.c. These are the three tracking frequencies.

BROADCAST BAND

Shift wave change switch to broadcast position. Replace the 400 ohm dummy antenna with a 200 Mmfd. mica condenser. Apply signal to same input. (Caution—Applying the signal from the generator to the set through the antenna hank may cause serious misalignment.) Apply a 600 k.c. signal. Rotate variable condenser until dial scale pointer indicates 600 k.c. Adjust padder screw C11 until signal is approximately maximum. Disengage variable condenser. Apply 1750 k.c. signal. Turn trimmer C9 to max. sig. Adjust trimmer C10 for max sig. Turn variable condenser until dial indicator reads 1500 k.c. Adjust C9 until signal is maximum at this point. Shift variable condenser to 600 k.c. Apply this frequency on the generator. Note the direction in which this frequency has shifted on the dial scale. Accordingly this will determine whether C11 should be increased or decreased to effect a meeting of the oscillator circuit with the antenna circuit by the usual "rocking" process. Return again to 1500 k.c. on both generator and dial scale of the receiver; if necessary make a slight adjustment of C9 until signal is maximum at this point.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected. In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 456 kilocycles to 18 megacycles. The generator should have adjustable signal output.
2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.
3. An insulated or non-metallic screw driver for the adjustment of trimmers.

I F ALIGNMENT 456 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to broadcast position. Turn the volume control to its maximum position.
2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the converter tube through a series .1 Mfd condenser. Set test oscillator to 456 KC.

Models 85 and 86 have a two point selectivity or high fidelity control associated with the tone control. This adjustment should be set for highest selectivity during alignment. Highest selectivity is obtained when the switch at the end of the tone control action is in its left or counterclockwise position.

3. Model 850 has this same control as a separate adjustment (second knob from the left). This adjustment should also be in its left hand or counterclockwise position during alignment.
4. Adjust I. F. alignment screws of second I. F. transformer adjacent to power tube to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.
5. Adjust alignment of first I. F. transformer (directly behind tuning condenser) to maximum output as described above.

6. Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.

6. Connect "hot" lead of test oscillator to receiver antenna lead in series with 200 Mmfd. condenser, and tune receiver to 550 kilocycles.
7. Adjust C-37 for minimum receiver output.

NOTE: Since coils are used in series it is absolutely necessary to align the high frequency bands first, in the order indicated.

FOREIGN BAND 5.7 TO 18.5 MEGACYCLES

1. With test oscillator connected to the antenna

and ground terminals through a 400 ohm resistor set oscillator at 16 megacycles.

2. Set the dial scale to 16 megacycles and adjust the oscillator trimmer condenser (C 4) to a resonance using the counterclockwise or low capacity point.
3. Adjust input circuit trimmer (C 5) to maximum response, rocking the gang condenser back and forth a degree or two to obtain proper maximum.

POLICE OR MIDDLE BAND 1.75 TO 5.8 MEGACYCLES

1. With the test oscillator connected as above set the oscillator and dial to 5.5 megacycles.
2. Adjust oscillator trimmer condenser (C 6) for maximum response using the counterclockwise or low capacity point.
3. Adjust input circuit trimmer (C 7) to maximum response rocking the gang condenser as described above.

BROADCAST BAND 535 TO 1800 KC

1. With test oscillator connected to antenna and ground through a 200Mmfd. condenser set oscillator and receiver dial to 1600 kilocycles.
2. Adjust broadcast oscillator trimmer (C 8) to obtain maximum response.
3. Adjust antenna circuit trimmer (C 9) for maximum output.
4. Adjust presselector trimmer (C 10) for maximum output.

5. Set test oscillator and dial to 600 kilocycles and tune in the signal, then adjust broadcast band padding condenser (C 11) for maximum output. This paddler is mounted on the aluminum coil deck near the panel and is adjusted through a hole provided in the back of the chassis pan. Rock the condenser back and forth a degree or two in order to obtain proper maximum.

6. Repeat the 1600 KC adjustments described above for greater accuracy.

MODEL 1050

MODEL 850

7. Repeat adjustments described under 3, 4, and 5 for greater accuracy.

POLICE OR SECOND BAND

1. Turn the wave switch to second or police band. Leave oscillator connected as above but with the output set to 5000 KC and the .00025 Mfd. condenser replaced by a 400 ohm resistor. Set dial scale to 5 MC on the second band. Adjust oscillator trimming condenser C8 for maximum output, observing as before that the proper point occurs at the minimum or counter-clockwise position of the screw as two points are found.
2. Adjust detector input trimming condenser, C13, to maximum, while rocking the tuning condenser slightly for maximum response.
3. Adjust antenna stage trimmer, C5, for maximum output.
4. Set test oscillator to 2000 KC and tune in the signal. Adjust oscillator padding condenser, C11, for maximum output, while rocking the tuning condenser as described above.
5. Repeat operations 1, 2 and 3 to assure precise alignment.

FOREIGN OR THIRD BAND

1. With the test oscillator connected the same as above and set to 16000 KC (16MC) set the dial to 16MC on the third band.
2. Adjust oscillator trimming condenser, C7, for maximum response. Use lower capacity or counter-clockwise response point.
3. Adjust detector input trimmer, C12, to maximum, rocking tuning adjustment.
4. Adjust antenna trimmer, C4, for maximum response.

ULTRA HIGH FREQUENCY OR INSIDE BAND

This band was adjusted at the factory and will not require further adjustment.

Fig. 2 Location of Trimmers

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected. In order to properly realign the receiver the following equipment is necessary:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 456 kilocycles to 18 megacycles. The generator should have adjustable signal output.
2. An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.
3. An insulated or non-metallic screw driver for the adjustment of trimmers.

I F ALIGNMENT 456 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to broadcast position. Turn the volume control to its maximum position.
2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd condenser. Set test oscillator to 456 KC.
3. Turn selectivity control (second from the left) to its high selectivity position. This is the left hand or counter-clockwise position.
4. Adjust I. F. alignment screws C17 and C18 of the output transformer to maximum output, reducing output of test oscillator to keep meter reading on scale at alignment proceeds.
5. Adjust alignment screws, C15 and C16, of input transformer to maximum output as described above.
6. Readjust all four alignment screws to insure accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.
7. Connect "hot" lead of test oscillator to receiver antenna lead in series with 250 Mmfid condenser and tune receiver to 550 kilocycles.
8. Adjust C-46 for minimum receiver output.

R. F. ALIGNMENT BROADCAST BAND

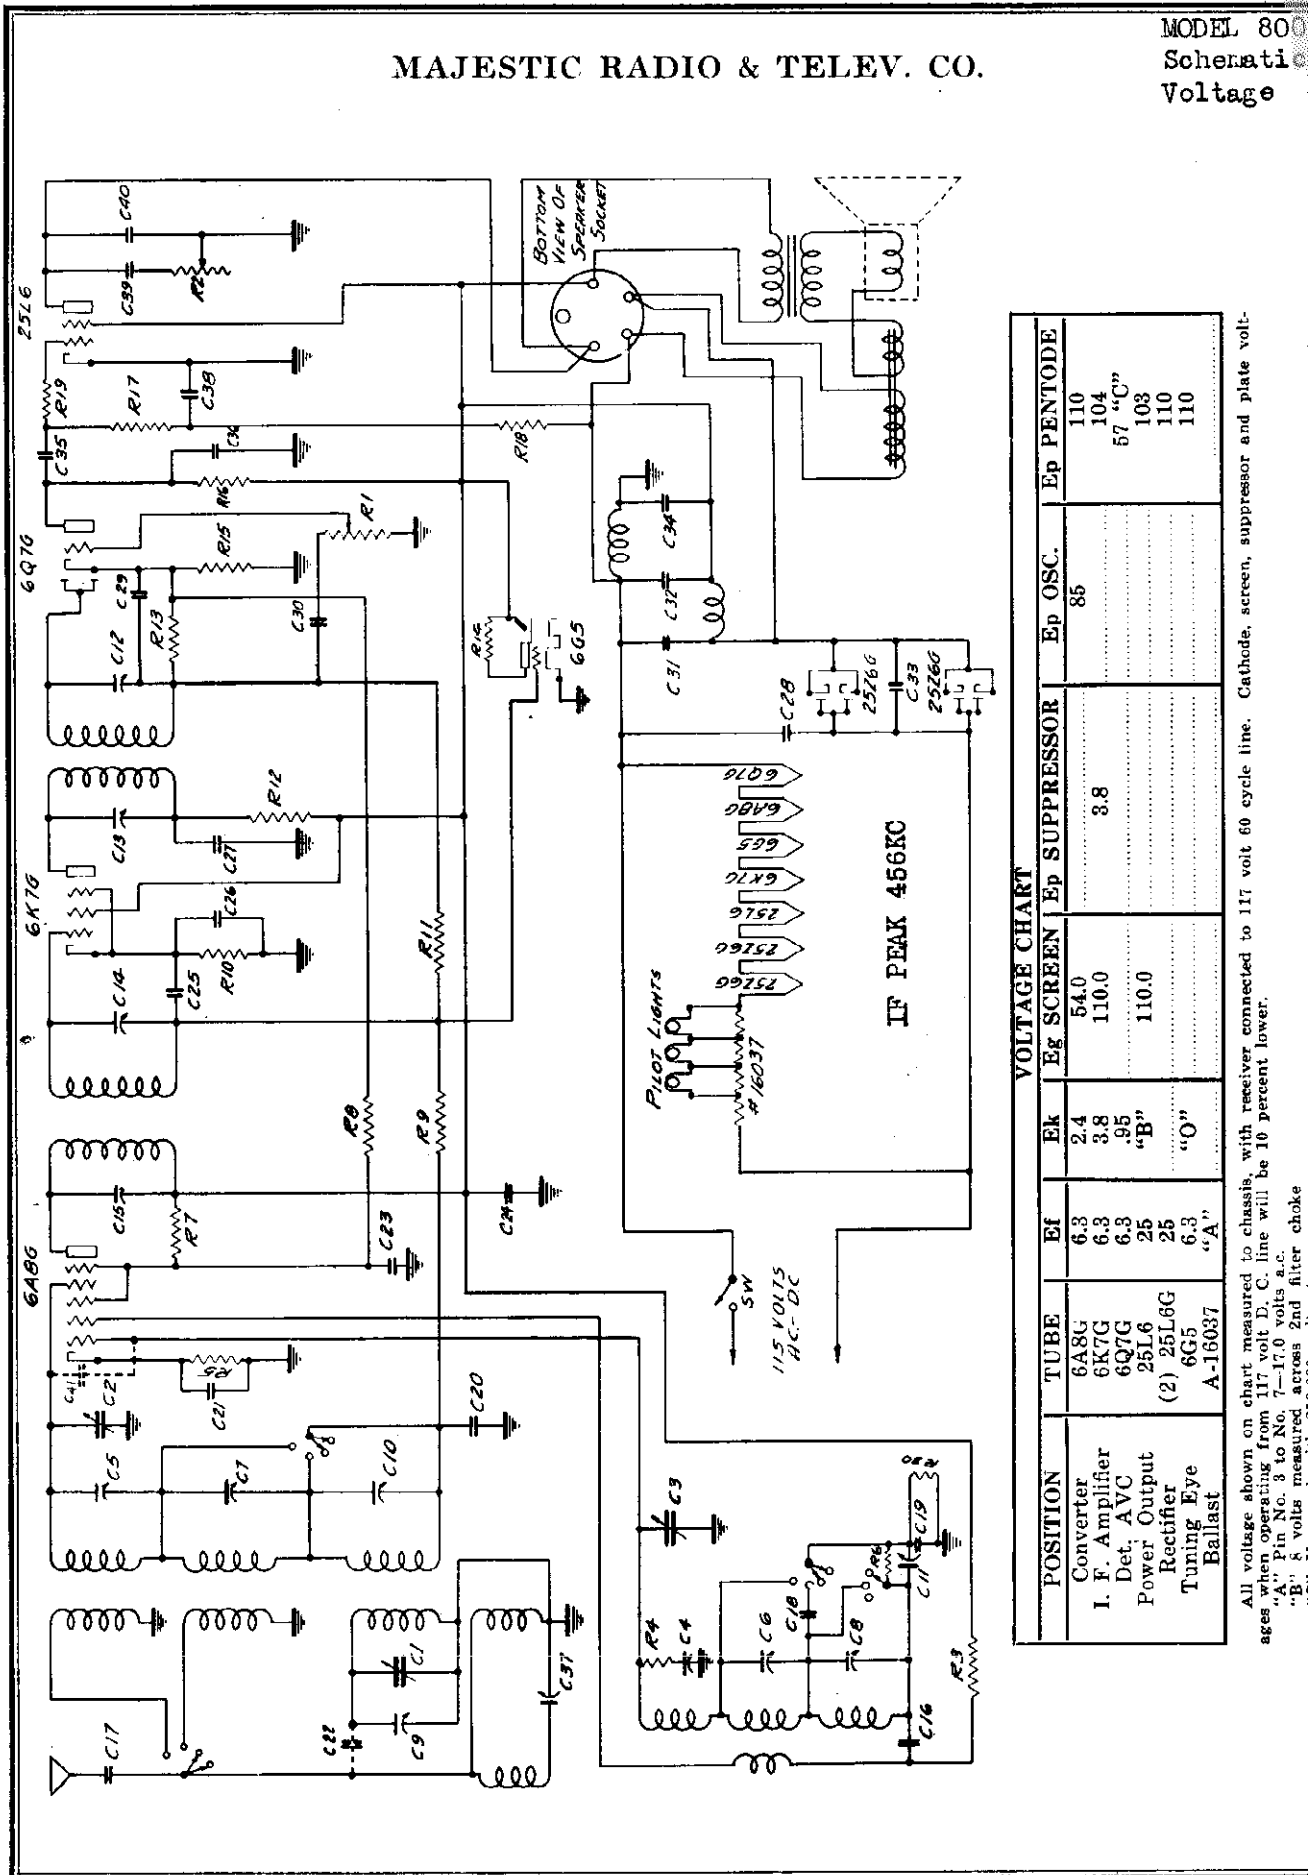

1. With test oscillator connected to the antenna post through .00025 Mfd., set signal generator to 1600 KC.
2. Set travelite indicator to end of scale (beyond 550 KC calibration) with gang condenser fully meshed at maximum capacitance.
3. Set dial to 1600 KC. Adjust broadcast oscillator trimming condenser, C9, for maximum output meter reading.
4. Adjust detector input trimmer, C14, to a maximum.
5. Adjust antenna stage trimmer, C6, to a maximum.
6. Set test oscillator to 600 KC and tune in the signal, then adjust broadcast oscillator paddler, C10, for maximum output. Rock the main tuning adjustment back and forth a degree or two in order to obtain proper maximum.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all wave receivers. The receivers are properly aligned at the factory with precision equipment, and realignment should not be attempted by the service technician until all other causes of faulty operation are corrected. In order to properly realign the receiver the following equipment is necessary:

- A signal generator which will provide an accurately calibrated signal at any frequency from 456 kilocycles to 18 megacycles. The generator should have adjustable signal output.
- An output audio voltmeter of the low voltage type to be connected across the moving coil of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.
- An insulated or non-metallic screw driver for the adjustment of trimmers.

I. F. ALIGNMENT 456 KC

- Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to broadcast position. Turn the volume control to its maximum position.
- Connect the test oscillator ground to chassis in series with .25 Mfd 600 volt condenser, and the "hot" lead from the test oscillator to the grid of the 6A8G converter tube through a series .1 Mfd. condenser. Set test oscillator to 456 KC.
- Adjust I. F. alignment screws of second I. F. transformer (at rear corner of chassis) to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment proceeds.
- Adjust alignment of first I. F. transformer (rear front corner of chassis) to maximum output as described above.
- Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confusing proper adjustment.
- Connect "hot" lead of test oscillator to receiver antenna lead in series with 200 Mmfd. condenser.
- Adjust C37 for minimum output, increasing test oscillator output until a signal is heard when C37 is adjusted for minimum output.

NOTE: Since coils are used in series it is absolutely necessary to align the high frequency bands first in the order indicated.

FOREIGN BAND 5.7 TO 18.5 MC

- With test oscillator connected to the receiver antenna lead through a 400 ohm resistor, set oscillator at 16 megacycles.

State serial number of receiver when ordering parts.

POWER LINE VOLTAGE
The model 800 is designed to operate on 105 to 125 volts, 50-60 cycles a.c. or d.c. Serious damage may result if the set is connected to a power supply other than that shown above. If there is any doubt in your mind, do not plug in the set until you first determine the voltage and cycles from your power supply company.

MODEL 1250

Socket, Trimmers
Voltage, Alignment

MAJESTIC RADIO & TELEV. CO.

I. F. ALIGNMENT 456 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to extreme clockwise position (broadcast band). Turn the volume control to maximum position. Rotate the hi-fidelity switch to the counter-clockwise position and the volume control to the "treble" or clockwise position.
2. Connect the test oscillator ground to chassis and the "hot" lead from the oscillator to the grid of the 6L7 converter tube through a series .1 mfd. condenser. Set test oscillator to 456.0 KC.
3. Adjust I. F. alignment screw of 3rd I. F. assembly, at rear of chassis, to maximum output, reducing output of test oscillator to keep meter reading on scale as alignment proceeds.
4. Adjust I. F. alignment screws of 2nd I. F. transformer adjacent to 3rd I. F. transformer, for maximum output as described above.
5. Adjust alignment screws of 1st I. F. transformer, near front of chassis, for maximum output as described above.
6. Re-adjust alignment screws of all three transformers to make sure of accurate alignment. Always use lowest possible output of test oscillator to preclude the possibility of the automatic volume control action confusing correct alignment.

WAVE TRAP ADJUSTMENT

1. With test oscillator still set at 456.0 KC remove series condenser from grid of 6L7 converter tube and substitute a 200 mmfd. condenser in its place.
2. Connect test oscillator lead to antenna post of receiver.
3. Keep variable condenser at maximum capacity position with wave band switch in broadcast position.
4. Raise output of test oscillator until a half scale meter deflection is obtained.
5. Adjust trimmer No. C-25 (located on chassis) until the meter reading is at the minimum deflection (toward zero).

BROADCAST BAND—535-1720 KC

1. Set test oscillator to 1600 KC. Connect oscillator to receive through a 200 mmfd. condenser.
2. Rotate wave band switch to full clockwise direction.
3. Set dial scale to 1600 KC, and adjust trimmer C-19 to a resonance.
4. Adjust trimmer C-18 for maximum response.
5. Adjust trimmer C-6 for maximum response.
6. Set test oscillator to 600 KC.
7. Set dial scale to 600 KC and adjust padding condenser C-13 for maximum response "rocking" gang condenser while adjustment is made, to obtain proper resonance.
8. Repeat the adjustments at 1600 KC to obtain greater accuracy.

WEATHER BAND—140-410 KC

1. Set test oscillator to 400 KC. Use 200 mmfd. condenser in series with oscillator lead.
2. Rotate wave band switch one position in counter-clockwise direction.

3. Set dial scale to 400 KC and adjust trimmer C-14 to a resonance.
4. Adjust trimmer C-19 to a maximum response.
5. Adjust trimmer C-7 to a maximum response.
6. Set test oscillator to 160 KC.
7. Set dial scale to 160 KC and adjust padding condenser C-15 to maximum response, "rocking" gang condenser while adjustment is made, to obtain proper resonance.

POLICE BAND—1.7-5.8 Megacycles

1. Set test oscillator to 5.5 megacycles, (400 ohm resistor in series with oscillator lead).
2. Rotate wave band switch counter-clockwise one position.
3. Set dial scale to 5.5 megacycles, and adjust C-10 to a resonance. The resonance obtained with the trimmer in the low capacity direction, being the correct one.
4. Adjust trimmer C-17 to a maximum response, "rocking" gang condenser while adjustment is made, to obtain proper resonance.
5. Adjust trimmer C-5 to a maximum response, "rocking" gang condenser while adjustment is made, to obtain proper resonance.
6. Set test oscillator to 2.0 megacycles.
7. Set dial scale to 2.0 megacycles, and adjust padding condenser C-11 for maximum response, "rocking" gang condenser while adjustment is made, to obtain proper resonance.
8. Repeat the adjustments at 5.5 megacycles to obtain greater accuracy.

FOREIGN BAND—5.6-18.0 Megacycles

1. With test oscillator connected to the antenna and ground terminals through a 400 ohm resistor, set oscillator at 16.0 megacycles.
2. Rotate the wave band switch to the 4th position in the counter-clockwise position. Set dial scale to 16.0 megacycles.
3. Adjust oscillator trimmer C-8 to a resonance. There will possibly be two resonant points noticed. The one obtained with the trimmer out in the minimum capacity direction, is the correct one.
4. Adjust trimmer C-16 to maximum response, "rocking" the gang condenser back and forth a degree or two to obtain proper resonance.
5. Adjust trimmer C-4 to maximum response, "rocking" gang condenser while trimming to obtain proper resonance.
6. Set test oscillator to 6.0 megacycles.
7. Set dial scale to 6.0 megacycles, and adjust padding condenser C-9 until a maximum response is obtained, "rocking" the gang condenser while adjustment is made to obtain proper resonance.
8. Return to 16.0 megacycles and check adjustment of C-8, C-16, and C-4 to make certain that the adjustment of C-9 has not disturbed their adjustments.

**ULTRA HIGH FREQUENCY BAND
16.5-42.0 Megacycles**

The alignment of this band is fixed at the factory and does not have any adjustments to be made in the field.

Schematic, Alignment
Voltage

- (2) Connect signal generator to antenna post on set through a standard dummy antenna. Remove short circuit from condenser. Set generator and dial to 1500 k.c. and peak variable condensers for maximum output on meter. For low frequency adjustment set dial at 600 k.c. and peak padding condenser on front of chassis. Short wave calibration is automatically taken care of by fixed calibrated trimmers and padders. No need for further adjustment.

NOTE
On Long Wave Model use Trimmers C1 & C2. Also replace C13 with Padder C8. E & M Band coils are replaced with E Band coils.

- (1) Set signal generator to 456 k.c. and connect output meter from plate of 43 tube to ground. Connect output of signal generator to grid of 6A8 tube. Ground stator of front section of variable condenser. Adjust both grids and plate trimmers of 1st and 2nd I.F. transformers for maximum gain on output meter.

Apply 450 kc to control grid of Mixer, after removing grid cap. Adjust the two i-f transformers' trimmers to maximum AVC voltage developed.

Disengage completely plates of variable condenser. Apply signal of 1712 kc to antenna and adjust trimmers on top of the variable condenser to maximum output. Rotate condensers until one section of the split plates are engaged and bend plates for maximum output. Be sure to change oscillator frequency with each move to a new section.

INSTRUCTIONS FOR REBALANCING 6 TUBE 1934 MODEL DUAL
 WAVE RECEIVER. MODEL AE AND AL

Remove the control grid cap of the 2A7 tube (mixer) and apply a modulated signal of 450 K.C. to the control grid of the 2A7 tube. Trim the first and second I.F. Transformers for maximum AVC voltage developed. Be sure during the alignment procedure to keep the signal input down as low as possible or double peaking of stations will result. There are two adjustments on each of the I.F. transformers.

To align the R.F. and Osc. and Mixer circuits on the AL Model --

Turn the wave band switch to the A position (all switch contacts open), turn the variable condenser until the plates are entirely engaged. Apply a signal of 530 K.C. to the antenna connection of the receiver and adjust the A band padder until the oscillator signal is received at maximum. Apply signal of 1600 K.C. to the antenna connection of the receiver and turn the variable condenser until the plates are disengaged and trim the trimmers on the variable condenser until maximum signal is obtained. Adjust the Osc., Mixer and R.F., in order named.

To adjust the L band, apply a signal of 1600 K.C. to the antenna connection of the receiver and adjust the L band padder until maximum signal is obtained.

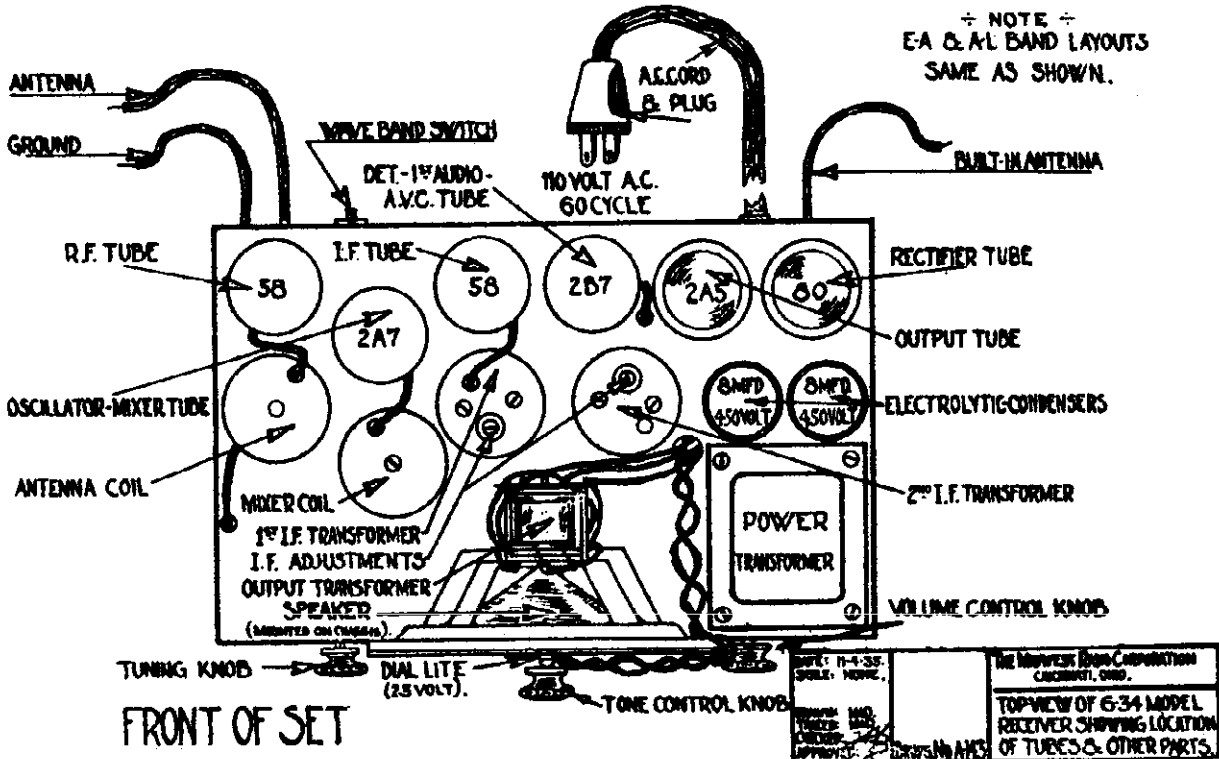

To align the R.F., Osc. and Mixer circuits of the AE model --

Turn the wave band switch to the A position (all contacts closed). Apply a signal of 530 K.C. to the antenna connection of the receiver and adjust the A band padder until maximum signal is received. Condensers being fully engaged or closed. Rotate condensers to the position where the plates are entirely disengaged. Apply a signal of 1600 K.C. to the antenna connection of the receiver and trim the adjustments on the variable condenser until maximum output is received.

Turn the wave change switch to the B position (all contacts open). Apply a signal of 150 K.C. to the antenna connection of the receiver, and adjust the E band padder until maximum signal is received. Rotate the variable condenser being closed for this operation.

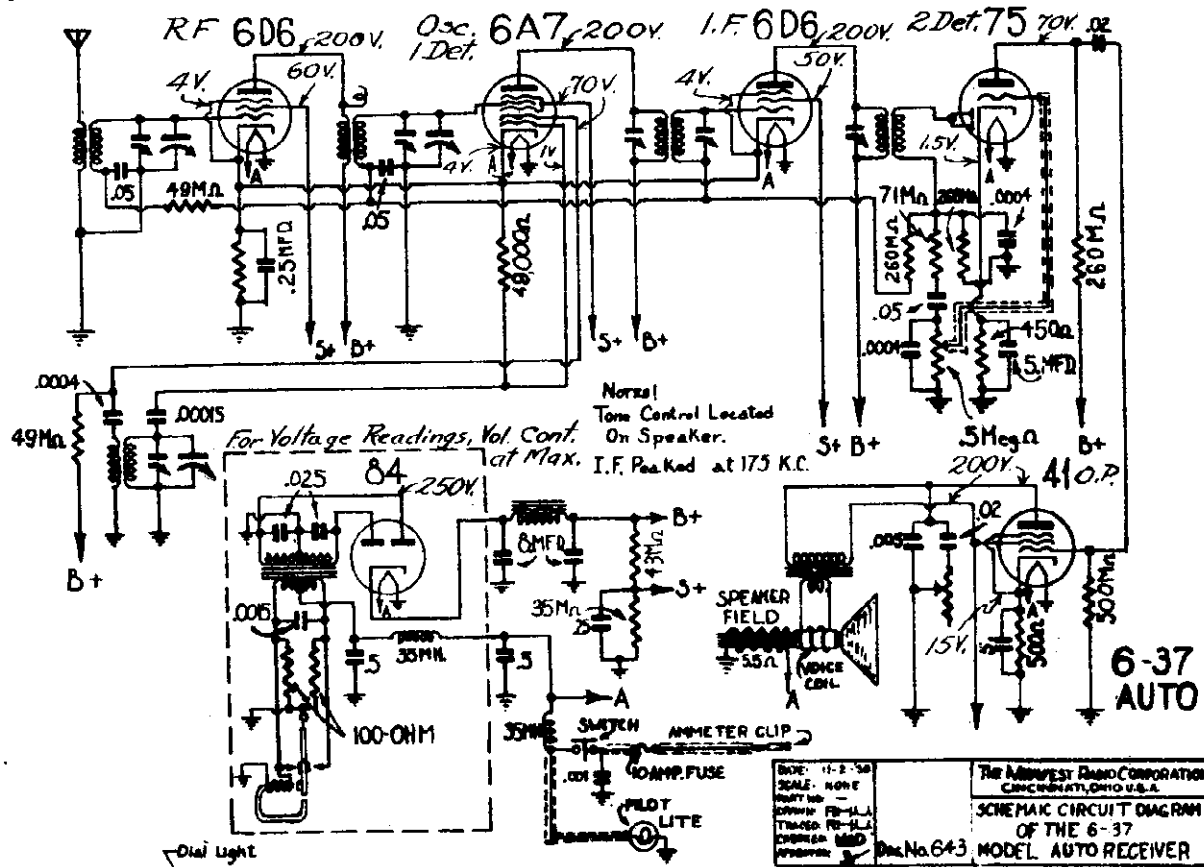

Turn the variable condensers to the position where the plates are entirely disengaged and apply a signal of 370 K.C. to the antenna connection of the receiver and adjust the trimmers on switch until maximum signal is received. This completes the procedure of rebalancing the receiver.

Be sure to always keep the signal input as low as possible when aligning a receiver.

Doc. No. 643

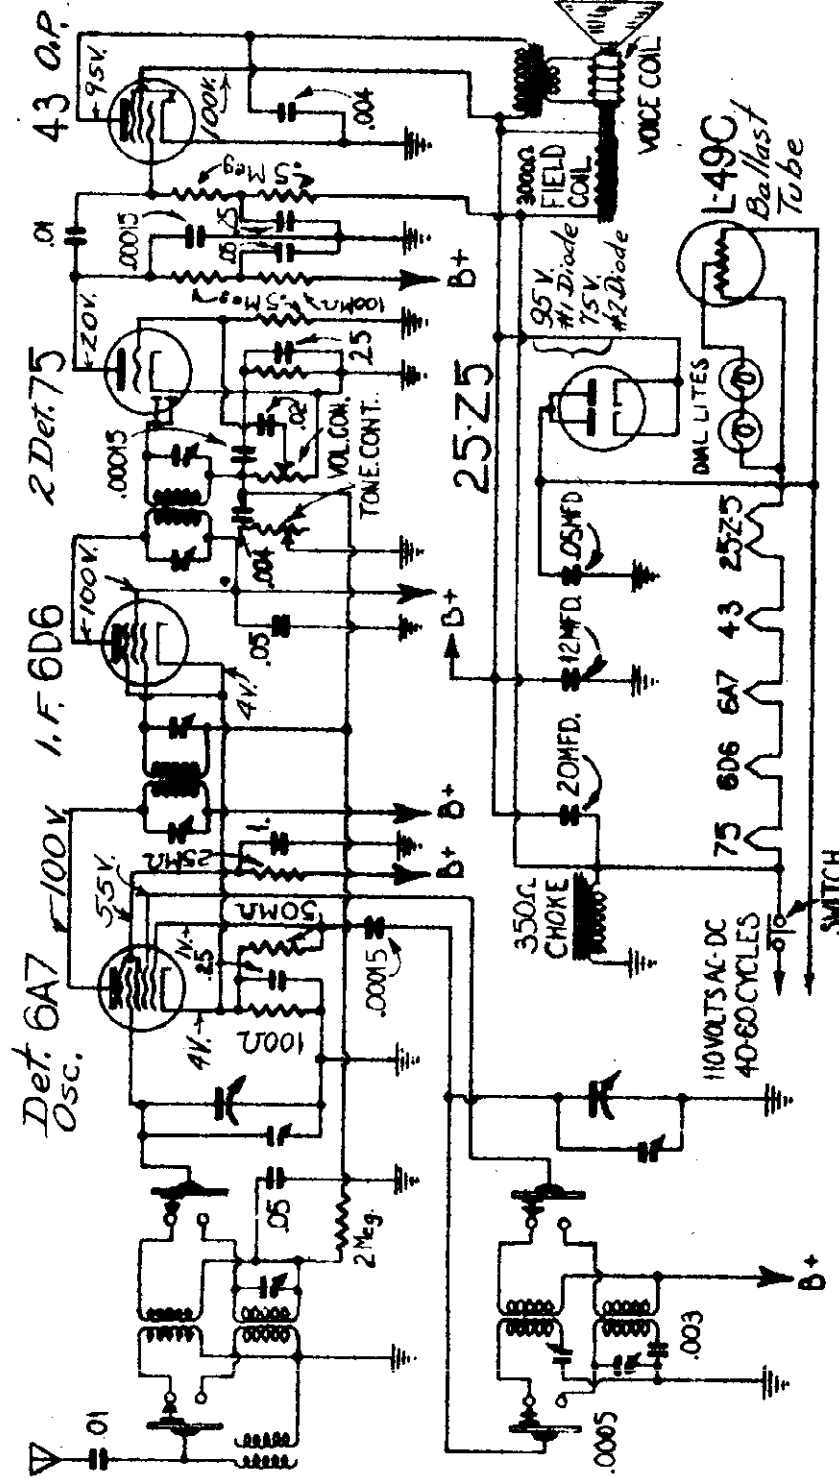

I-F ALIGNMENT: Connect signal generator set at 175 kc, to grid of 6A7 tube and ground stator of oscillator condenser during this operation. Peak trimmers of both i-f transformers for maximum.

R-F ALIGNMENT: Connect signal generator to antenna post of set through a standard dummy antenna. Remove ground from oscillator condenser. Set dial and signal generator to 1500 kc and align trimmers on variable condensers for maximum output. All other frequencies will be aligned automatically because of cut section oscillator condenser.

 Part No. 658

I-F ALIGNMENT: Signal generator to 456 kc and connect its output to grid of 6A7 tube. Short-circuit front section of variable condenser. Adjust trimmers of both i-f transformers for maximum.

R-F ALIGNMENT: Broadcast Band-- Remove short circuit from condenser. Connect signal generator, set at 1500 kc, to antenna post of receiver through standard dummy antenna. Set dial to 1500 kc and peak variable condenser trimmers for maximum. Set signal generator and dial to 600 kc and adjust padder for maximum output. Re-adjust 1500-kc alignment.
Short-wave Alignment-- Set signal generator and dial to 15 mc and peak trimmers for maximum output. Low-frequency setting is automatically cared for by fixed calibrated padder.

SCHMATIC CIRCUIT DIAGRAM
OF THE
7-36 AC-DC MODEL RECEIVER

All parts and connections indicated to the right of this dotted line are identical on both Models.

IF PEAK 456KC

MODEL 7-36 AC-DC
Socket, Trimmers
Alignment

MIDWEST RADIO CORP.

R.F. ALIGNMENT

- (2) Band #1 Alignment :- The short circuit is removed from oscillator condenser and the signal generator is connected to the antenna post of the receiver through a standard dummy antenna. The receiver and signal generator are set at 16 m.c. The oscillator trimmer is adjusted so as to bring in the signal at this setting. The antenna trimmer is adjusted for maximum output.
- (3) Band #2 Alignment: - With the signal generator still connected to antenna post of receiver, set generator and receiver dial at 1400 k.c. Adjust oscillator trimmer so that signal comes in at this setting. The Antenna and R.F. trimmers are adjusted for maximum output. The signal generator is set at 600 k.c. and the padder is adjusted so that the signal comes in at this point on the dial. After making this adjustment the 1400 k.c. adjustment should then be rechecked.
- (4) Band #3 Alignment: - With the receiver and signal generator both set at 325 k.c., the oscillator trimmer is adjusted so that this signal agrees with the dial. Antenna trimmer is then adjusted for maximum output.

Note: To assure more accurate trimmer setting always use lowest possible post oscillator output consistent with readable output meter scale deflection.

I.F. ALIGNMENT

Set signal generator to 1450 k.c. Connect output meter from plate of 43 output tube to ground. Connect output of signal generator to grid cap of 6K7 tube. The front section of the tuning condenser if short circuited and the volume control is turned to maximum gain on output meter.

Note: To assure more accurate trimmer setting always use lowest possible test oscillator output consistent with readable output meter scale deflection.

METAL TUBES ARE INTERCHANGEABLE WITH GLASS COUNTERPART TUBES. EXAMPLE:- METAL TUBE 6K7 MAY BE REPLACED WITH GLASS COUNTERPART TUBE 6K7-G

SCHEMATIC CIRCUIT DIAGRAM
OF THE 7-36

MODEL 7-36 Batt.
Socket, Trimmers
Alignment

MID-WEST RADIO CORP.

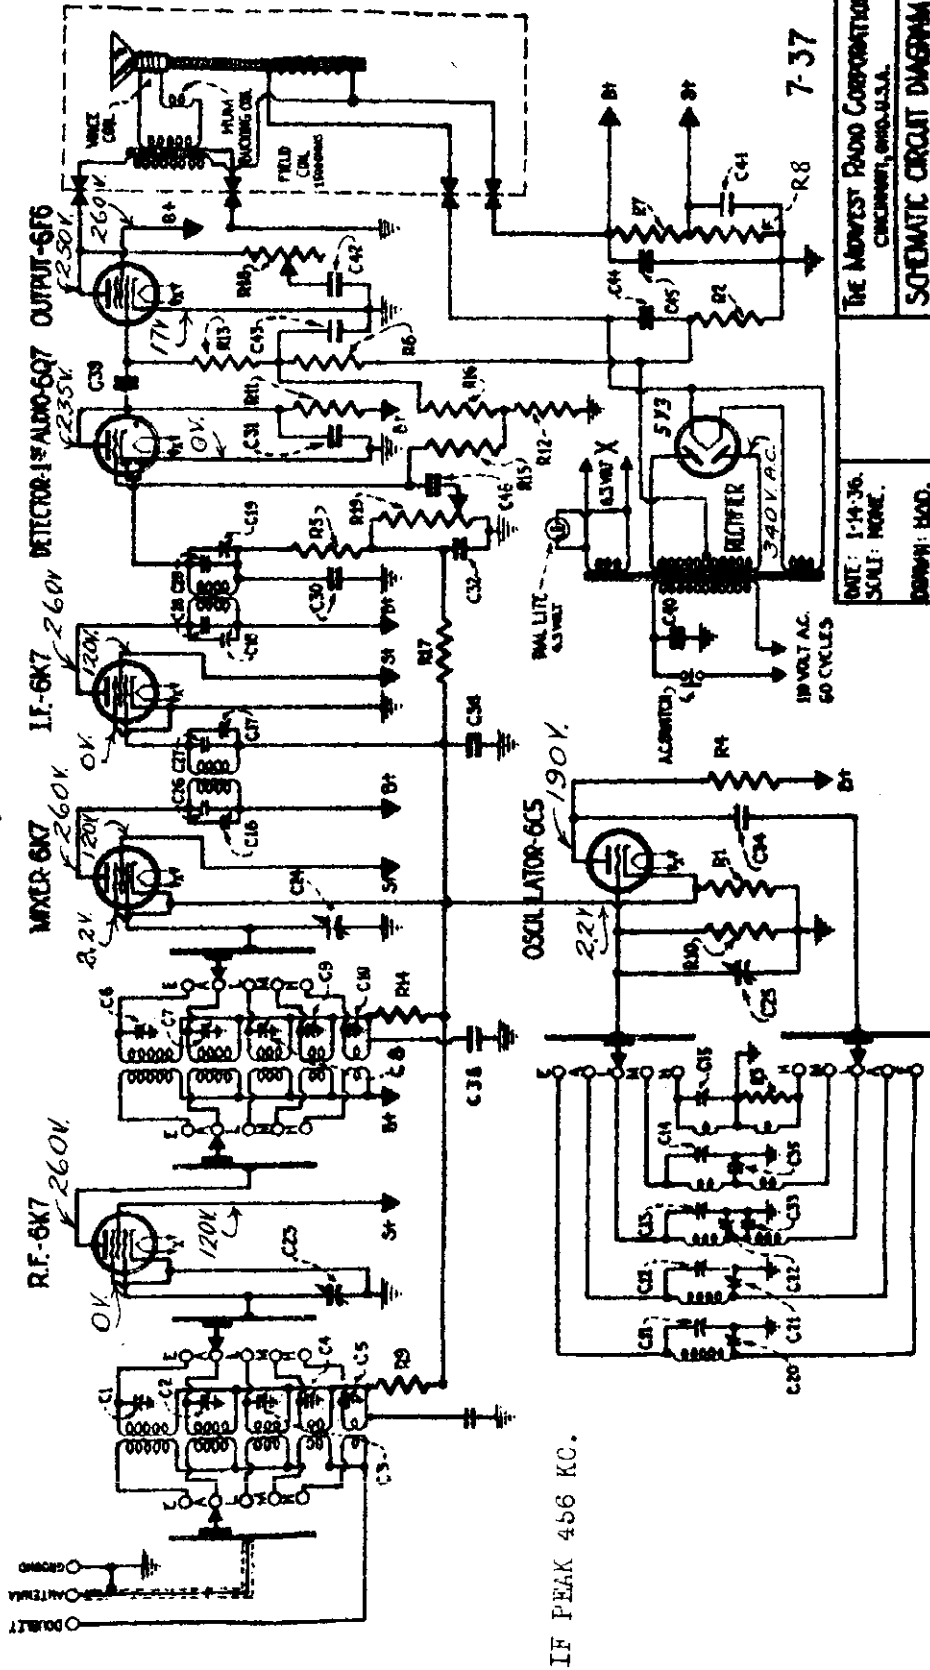

- (1) Connect output of signal generator to the control grid of the 106 tube through a .02 mfd. condenser. Leave the grid cap connected to the grid terminal of the tube and connect the ground side of the signal generator to the receiver ground. Set signal generator to 465 k.c. and connect output meter between plates of the 19 output tube. Adjust grid and plate trimmer screws of 1st and 2nd I. F. transformers for maximum gain.
 - (2) Connect output of signal generator to antenna post of receiver through a standard dummy antenna.
 - (a) Place band selector switch for operation on the 5.8 to 18.3 m.c. band. Tune the receiver dial and the signal generator to exactly 18.3 m.c. Adjust the 18.3 m.c. oscillator trimmer for maximum gain. Care must be taken that the fundamental peak and not the image peak is used for aligning the receiver at this frequency.
 - (b) Place band selector switch for operation on the 1.8 to 5.8 m.c. band. Set the signal generator and dial to a frequency of 5.8 m.c. Adjust 5.8 m.c. oscillator trimmer for maximum output. Adjust antenna trimmer for maximum output.
 - (c) Place band selector switch for operating on the 5.35 to 17.20 k.c. band. Set signal generator and dial to 17.20 k.c. and adjust oscillator trimmer for maximum output. Adjust 1400 k.c. R. F. and antenna trimmers for maximum output. Set signal generator and dial to 600 k.c. and adjust oscillator padder for maximum output.
- Set signal generator and dial to 16 m.c. and adjust antenna trimmer for maximum output.
- It will be necessary to recheck the 17.20 k.c. setting after this alignment.
