Service Notes

ALIGNMENT OF RECEIVER:

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need retracking. Only when an intermediate coil has become defective due to an open or burned out winding, should it be necessary to readjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the bottom of the chassis. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then recheck the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1895, 890, 650 and 500 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are especially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

Service Notes**

ALLIED RADIO CORP.

KNIGHT 7 TUBE SUPERHETERODYNE 1932 MODEL

INTERMEDIATE TRANSFORMERS:

The intermediate transformers are of the band pass type and of exceptionally high uniform gain. They are tuned to 175 kilocycles. The intermediate frequency trimmers are mounted on an isolantite base, preventing the transformer from becoming detuned due to the trimmer condensers absorbing moisture or warping. For this reason it should rarely, if ever, be necessary to re-track the intermediate frequency trimmers. In the event that it should be advisable to re-align the intermediate frequency coils, it is absolutely essential that a 175 kilocycle oscillator and an output measuring device be used.

ALIGNMENT OF RECEIVER:

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need re-tracking. Only when an intermediate coil has become defective due either to an open or burned out winding, should it be necessary to re-adjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the top of the intermediate shield can. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then re-check the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away, the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1295, 890, 650 and 550 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are especially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

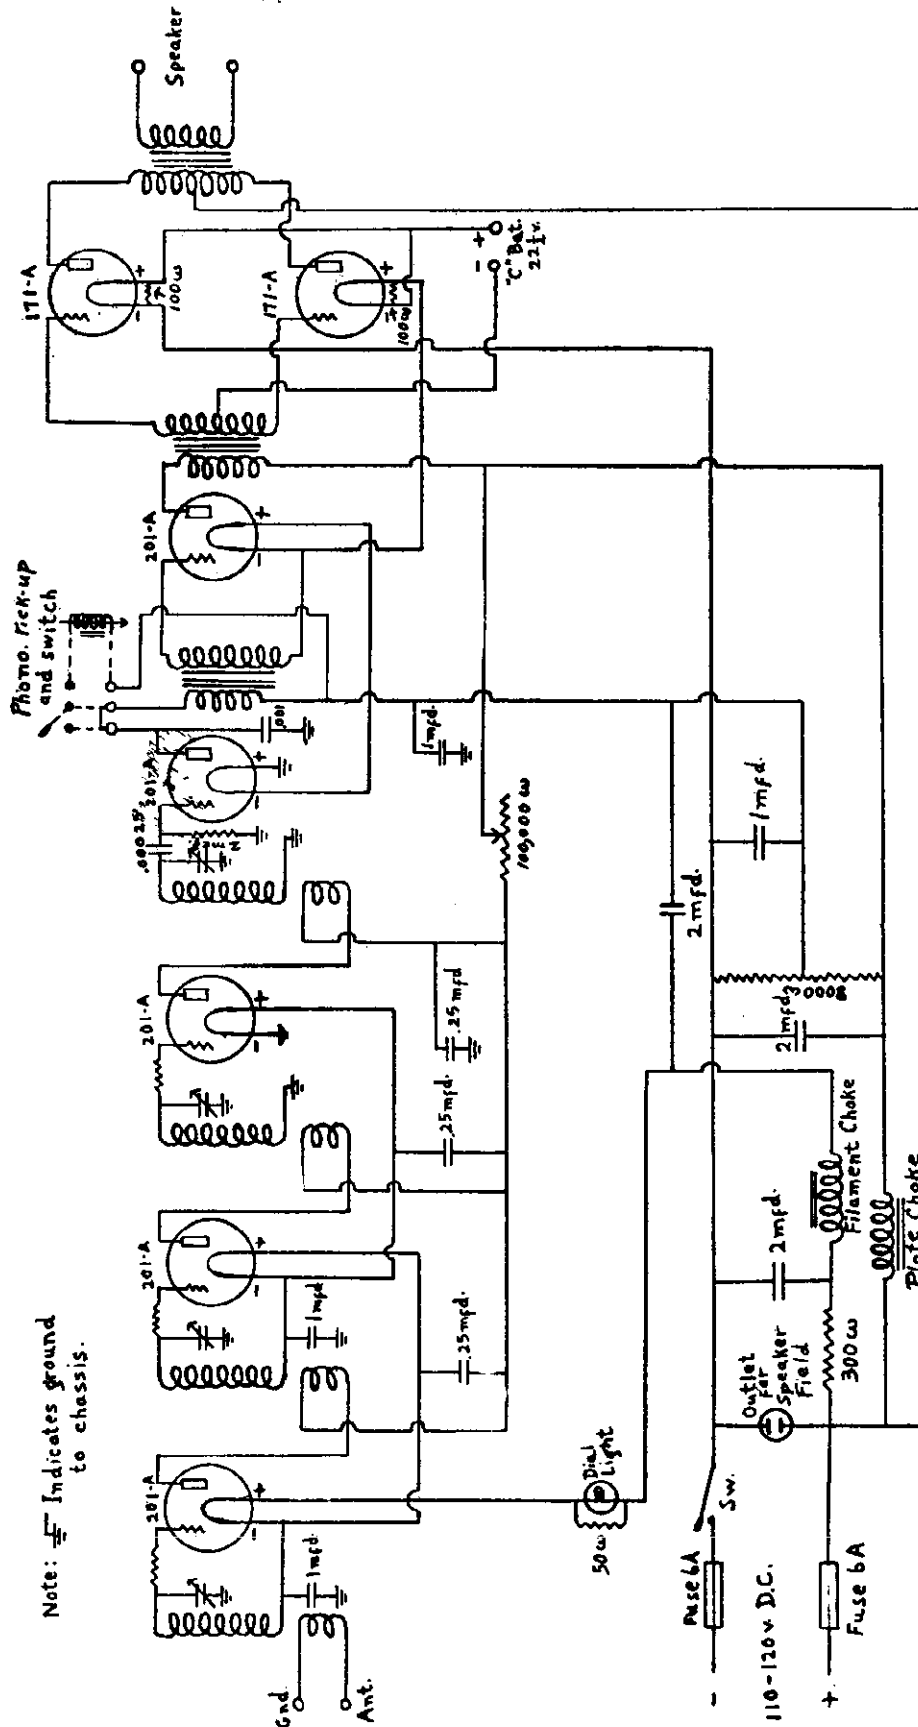

ELECTRO DYNAMIC SPEAKER:

The electro dynamic speaker has a tapped field winding - one section of which is 1320 ohms and is utilized as the second choke in the filter circuit. The other section, which is 500 ohms, is used to obtain the proper bias for the 247 tube, as well as acting as an additional filter choke.

MODEL Silver King DC
Combination

Continued from page 1-89
When operating as broadcast receiver, controls 1, 2 and 3 are used. 6 must be turned to the extreme left position.

The red wire goes to the antenna.
The shield wire goes to ground.
The power cable for A.C. is plugged into a 110 v., 60 cycle alternating current outlet and the power cable for D.C. is plugged into 110 v., D.C. line and polarity must be correct.

When it is desirable to receive short wave on television stations.
Rotate 3 to setting of drum dial indicated below
Rotate 4 to left.

Rotate 6 to band selected.
Extreme right position 80 to 200 meters.
2nd from extreme right 40 to 80 meter position.
3rd from extreme right 19 to 40 meter position.
Tune 3 to zero and adjust compensator 5 for loudest background or rushing noise.
Tune 3 very slowly and slightly readjust 5 until desired station is found.
Volume is controlled by 2 and desired tone is effected by 1.

To return to broadcast band.
Turn 4 to right.
Turn 3 until click is heard
Turn 6 to extreme left.
Your receiver is now adjusted for broadcast reception.

MODEL 46, 47, 53

Data

ATWATER KENT MFG. CO.

Model 46, 47 and 53 Receivers

General Description

Model 46 is similar to Model 43, except that the power unit is enlarged to provide adequate plate supply for the 171A-type tubes used in the 2nd A.F. stage. Also, the voltage regulator is not used, and the condensers in the power unit are contained in a separate replaceable section. Model 53 is a Model 46 with a type F-2C electro dynamic speaker mounted in a twenty six inch high metal cabinet.

Model 47 is similar to Model 46, but has four stages of R. F. amplification, with double R.F. transformers, thus providing greater sensitivity and selectivity.

The continuity tests given on page 103 may be applied to the receiver chassis of Models 46 and 53. The same tests may be applied to Model 47, with additional tests for the 4th R.F. socket contacts, which should give the same readings as the 2nd and 3rd R.F. sockets.

Special instructions for servicing the power unit in these three models are given below

Power Units in Models 46, 47 and 53

Apply the continuity test given in the table on page 104. If any one of the condensers is shorted or leaky, replace the condenser assembly. If the power transformer, filter-choke or output transformer is defective, replace the main sealed container, salvaging all other parts.

Replacing Condenser Assembly

Release panel assembly from power unit and remove panel-mounting strip by taking out the machine screw at each end. Unscrew two bolts holding the condenser assembly retaining-spring and take out the spring and supporting strip. Cut the three leads (white, blue, and green-yellow tracer), which connect between the condenser assembly and the transformer-choke assembly, at about the mid-point of each lead. Unsolder black lead from ground lug. Unsolder yellow lead and two black-red tracer leads from panel terminals. Unsolder leads at contacts of speaker-plug socket and socket 2Aa. Pull these leads up an inch or so through the hole in the socket-mounting angle and push the cable to one side

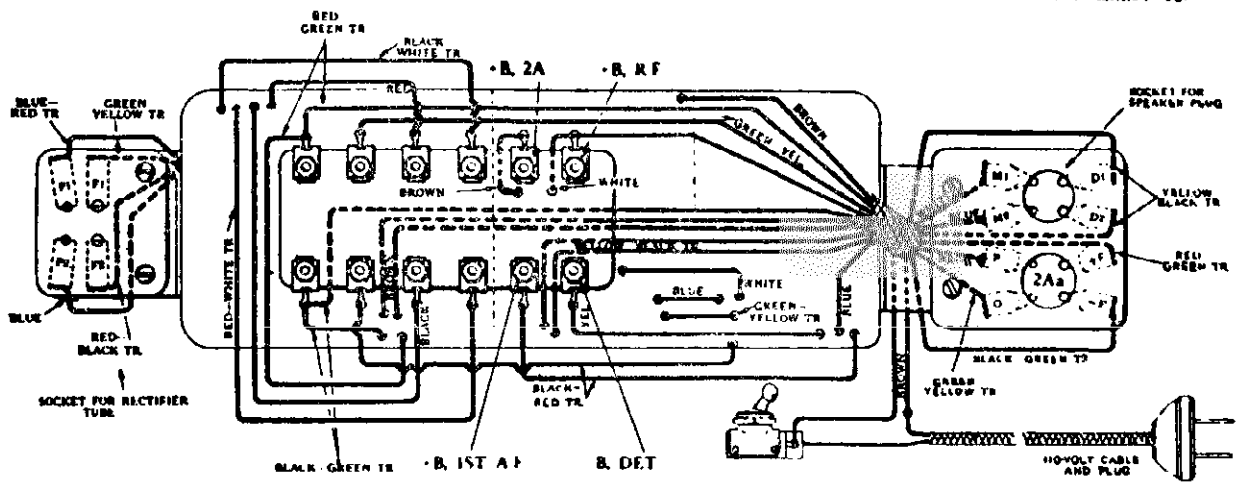

of the unit to allow room for removal of the condenser assembly. Take-out the assembly, pulling the blue M2 lead up through the cable covering.

Insert a new condenser assembly, reversing above procedure. Insulate the joints on the blue, white, and green-yellow tracer leads which connect the condenser assembly to the transformer-choke assembly

Replacing Transformer-Choke Assembly

Unsolder leads from socket plates at both ends of container and remove these sockets. Unsolder primary winding leads at points where they connect to the toggle switch and to one side of the 110-volt cable respectively. Release panel assembly from unit. Un-screw panel-mounting strip and condenser-retaining spring. Pull the primary leads, the yellow-black tracer output leads and the brown P2Aa lead (No. 18 wire) up through the cable covering. Cut the three leads (white, blue, and green-yellow tracer) which connect the transformer-choke assembly and the condenser assembly. Cut each lead at about the mid-point. Unsolder the six filament winding leads, the brown +B, 2A lead, and the white +B, R.F. lead from terminals on panel assembly. Unsolder black lead from ground lug. Remove the condenser and panel assemblies.

Substitute a new transformer-choke assembly, mount the salvaged parts and connect exactly like the original, reversing procedure outlined above

SHOWING CONNECTIONS AND APPROXIMATE POSITION OF LEADS FROM SEALED CONTAINER IN POWER UNIT FOR MODELS 46, 47 AND 53

This view shows the panel assembly moved to the left of its normal position. The replaceable condenser assembly is in the right hand end of the container. A black lead from the condensers assembly and a green lead from the transformer assembly are connected to a ground lug under the left hand panel mounting angle. In some units of this type the two leads to D1 and D2 are red (No. 18 wire) instead of yellow with black-tracer

VOLTAGE DATA

ATWATER KENT MFG. CO.

VOLTAGE TABLE

FOR MODEL 80, 81, 82, 82-D, 82-Q, 83, 84, 84-D, 84-Q, 85, 85-Q, 86, 87 and 89

The voltages listed in this table are only approximate, and are measured values, not actual operating values. Turn volume control to maximum.

Use 250-volt scale of a 1000-ohm-per-volt D. C. voltmeter.

All plate, screen and grid measurements are made from cathode in heater-type tube, and from -F in plain-filament-type tube.

When replacing a tubular resistor, use a resistor of the same color as the defective unit. However, if a resistor has been removed, or its identification destroyed, replace it with a resistor having the color that is specified in the diagram for that set.

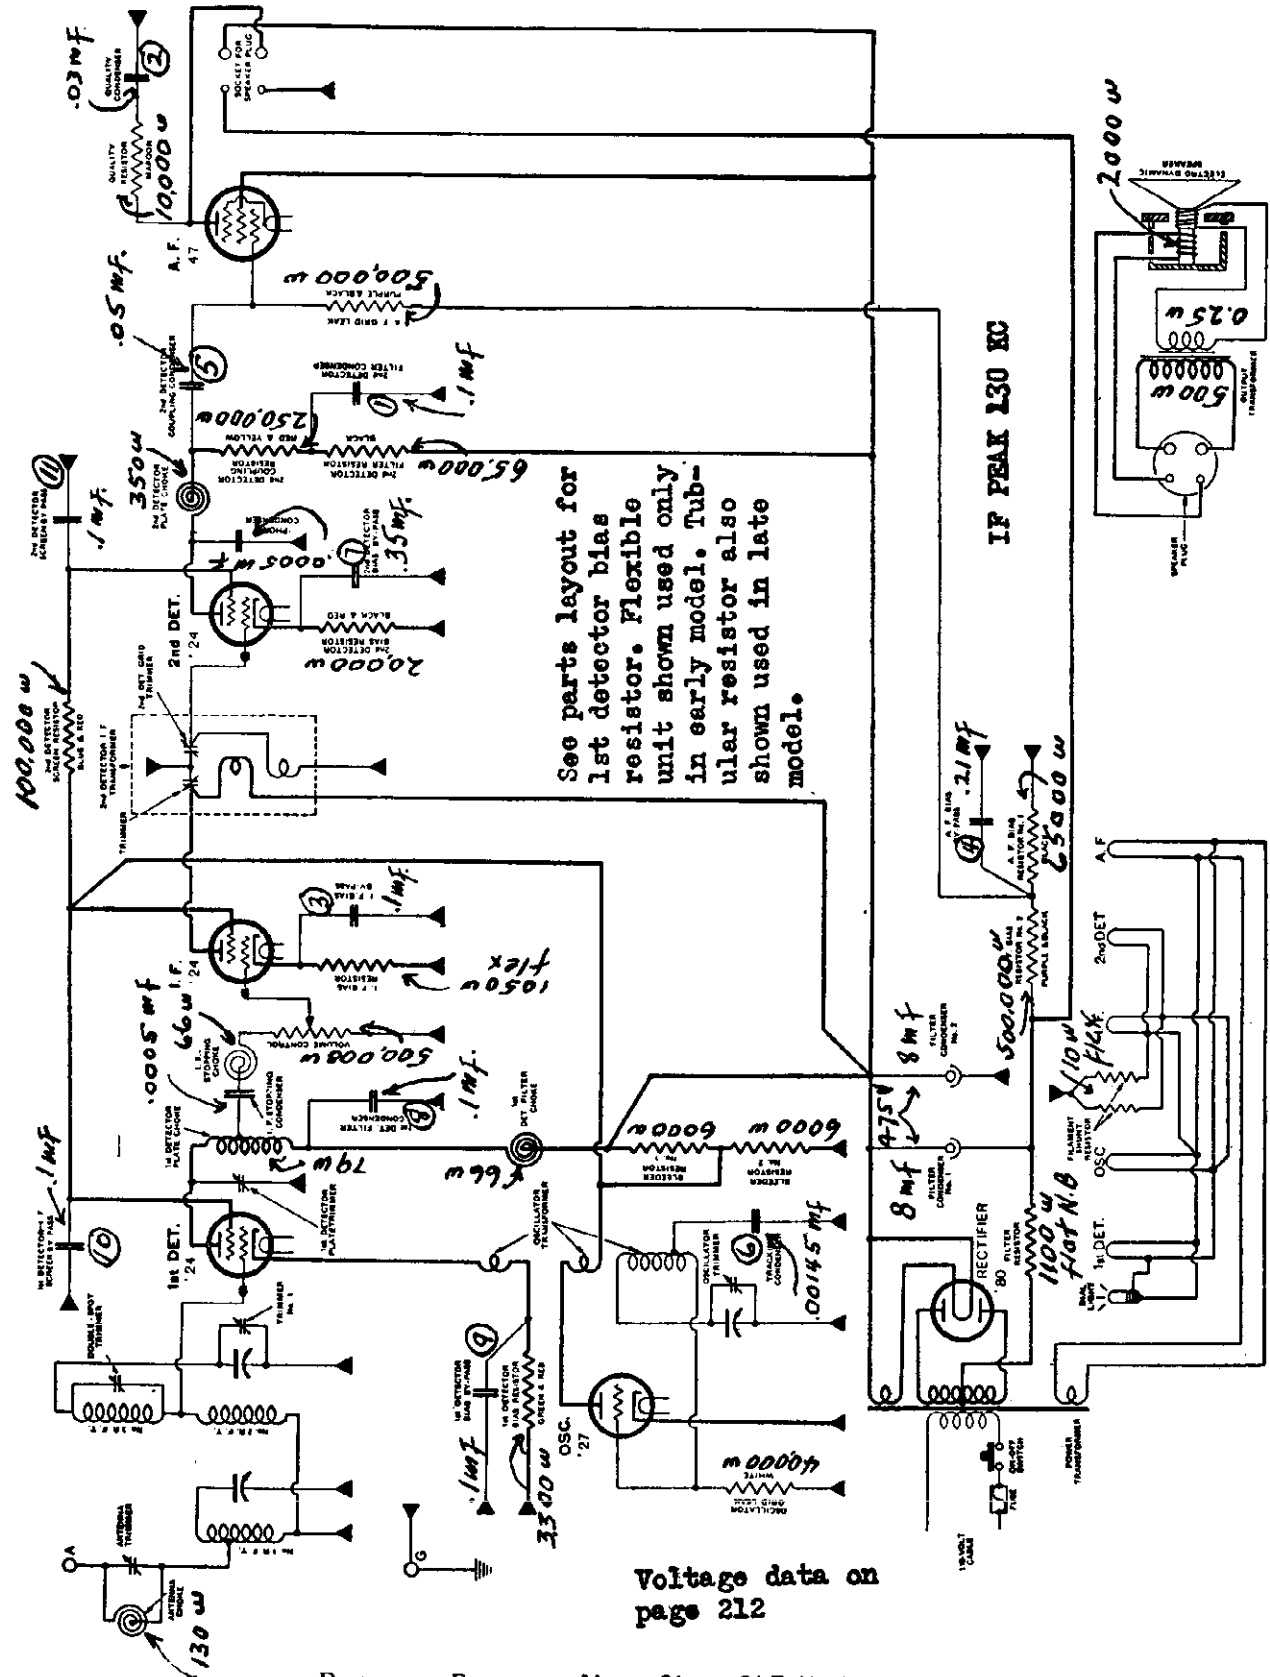

When replacing a tubular resistor, use a resistor of the same identifying color. In a few cases, owing to engineering changes, the color of a resistor in a chassis may not agree with the color specified in the diagram. In such a case, disregard the diagram and use a replacement resistor having the same color as the defective unit. However, if a resistor has been removed, or its identification destroyed, replace it with a resistor having the color that is specified in the diagram for that set.

GRID	4	4	4	4	4	4	4	4	4	4	4	4	4	4

* The measured oscillator grid voltage will vary dependent on the capacity of the voltmeter leads. In some cases, the presence of the leads will stop oscillation and no reading will be secured for grid bias. In other cases, the reading will be only slight, or it may be as high as 10 volts. This includes the 1st, 2nd and 3rd R. F. tubes in Model 81. † This is the detector tube in Model 81.

MODEL 84, 84-F
Early

ATWATER KENT MFG. CO.

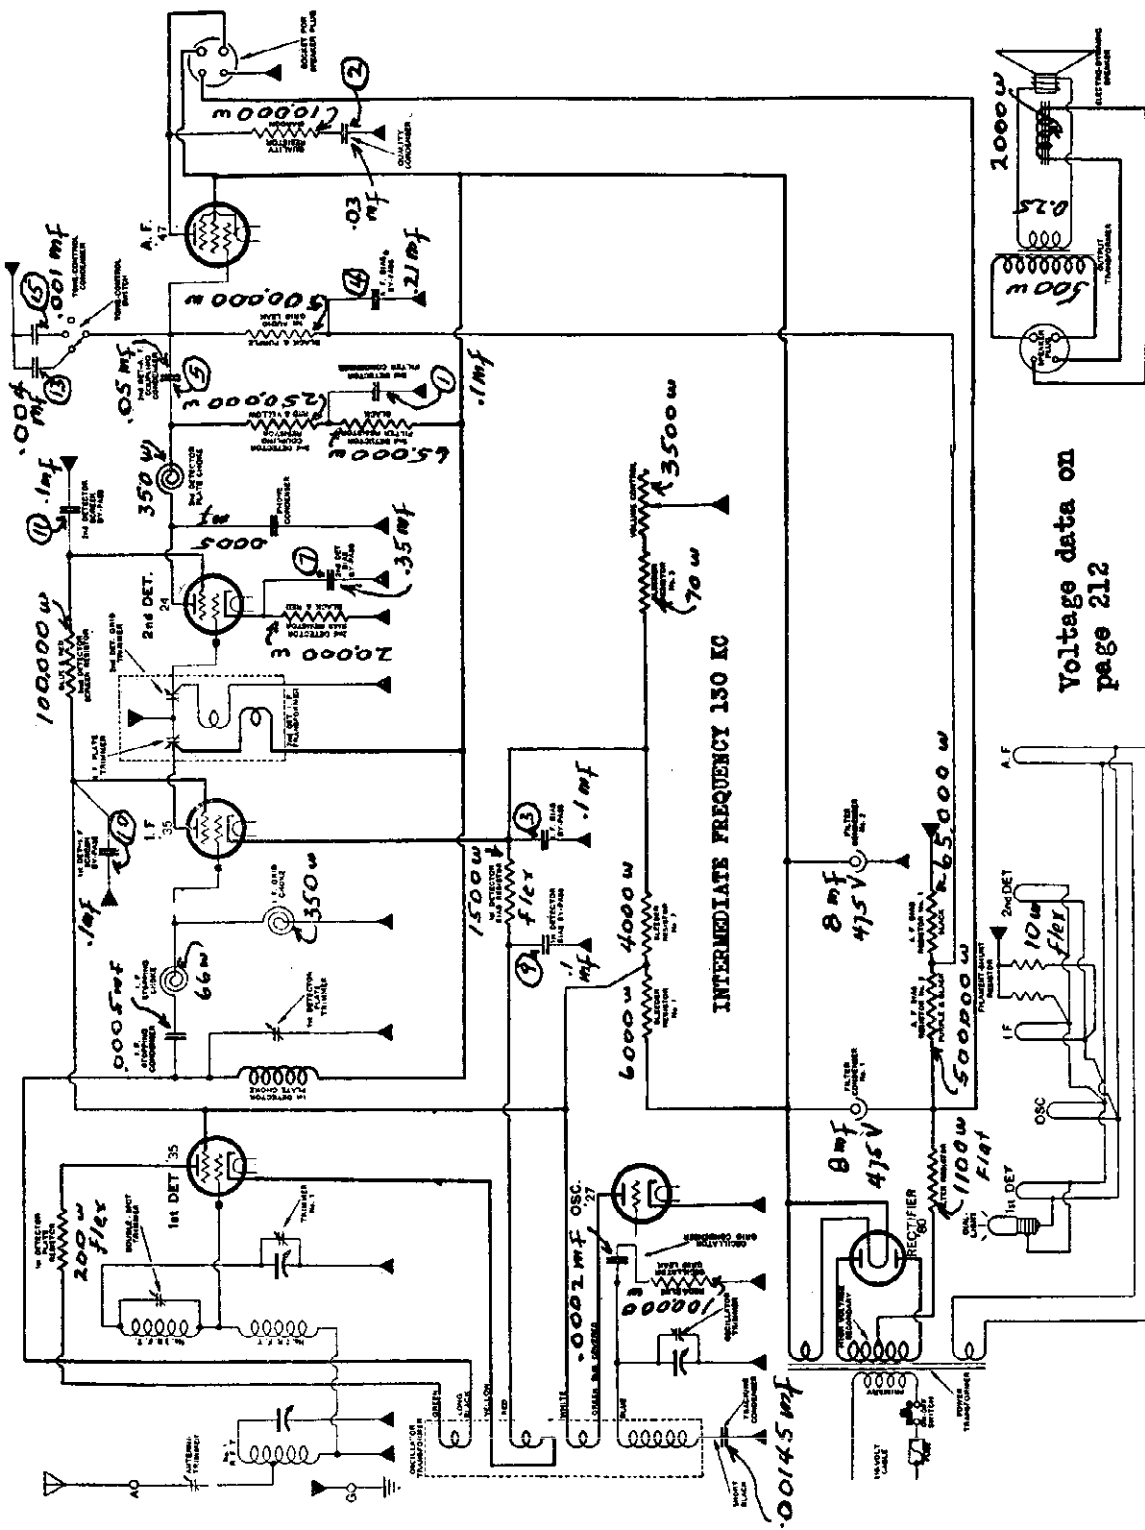

Voltage data on page 212

DIAGRAM OF EARLY-TYPE MODEL 84 AND 84-F (A. C.-OPERATED).

In Model 84-F, the filter resistor (connected in series with the center-tap of the high-voltage winding) is NOT used.

page 212

SPECIAL NOTE. Numerals within circles and adjacent to bypass condensers correspond with numbers marked within multi-section bypass condensers shown on parts layout. See next page.

DIAGRAM OF LATE-TYPE MODEL 84 AND 84-F (A. C.-OPERATED).
A few late-type Model 84 and 84-F receivers have slightly different oscillator transformers, as explained in the notes accompanying the parts list for these sets.
The filter resistor shown in the above diagram is NOT used in Model 84-F.
This set has a list-detector plate filter choke and condenser not shown in the diagram.

MODEL 84, 84-F CHARTS

MODELS 84, 84-F
Early and Late

ATWATER KENT MFG. CO.

CHART OF LATE-TYPE MODEL 84, 84-F.

Some late-type Model 84, 84-F receivers have slightly different oscillator transformers and connections than indicated in the diagram. When servicing such sets, carefully note and adhere to the original method of wiring. A flexible type 1st-detector bias resistor (not shown above) is connected from condenser 9 to condenser 3.

CHART OF EARLY-TYPE MODEL 84, 84-F.

In some early-type Model 84, 84-F, the 1st-detector bias resistor is a flexible type, and the quality resistor is wire-wound. These are both superseded by the tubular resistors indicated above. The filter-resistor at top-right is NOT used in any Model 84-F.

PHONOGRAPH
PICKUP

ATWATER KENT MFG. CO.

PHONOGRAPH PICKUP AND INDUCTION DISC MOTOR
(USED IN MODELS 75 AND 89-P)

DRAWING OF PHONOGRAPH PICK-UP AND ARM USED IN MODEL 75.

PHONOGRAPH PICK-UP
ARMATURE ADJUSTMENT

The armature-pivot bearings consist of two small strips of rubber (armature spacing cushions) which space the armature from the bearing surfaces on each pole piece.

The top end of the armature fits in a slit in a flat rubber damper. The damper is fastened to a small brass plate that may be adjusted to the right or to the left, in order to center the armature in the magnet gap.

If the armature is off center, as indicated by erratic reproduction, loosen the two round-head screws that hold the damper plate, and move the plate slightly to the right or left to a point where the armature is centered. Tighten the two screws.

When the armature is correctly centered, it should take as much force to move the needle to the left as to the right.

If the rubber damper plate or armature spacing cushions are dried out, or lack life, replace them with new pieces of rubber, which may be secured from your distributor.

If the pick-up magnet must be removed from the pick-up *FIRST* place a steel or iron keeper (a large nail will do) across the sides of the magnet poles, *THEN* remove the magnet.

Do *NOT* take off the keeper until *AFTER* the magnet is placed back on its pole pieces in the pick-up.

If the magnet is weak, have it re-magnetized, but be sure to place a keeper across the sides of the magnet poles before removing it from the magnetizer, and do not remove the keeper until after the magnet is placed back on its pole pieces in the pick-up.

CONTINUITY TESTS

Test across the two contacts on the neck of the mold pick-up back. The continuity reading should be nearly full. No reading indicates an open pick-up coil or leads.

Test from either contact on the pick-up to each pole piece, and to the armature. If there is any reading, it indicates that the pick-up coil or leads are grounded. This must be eliminated. Use two small pieces of thin cambric cloth to insulate the pick-up coil from the pole piece.

AUTOMATIC ELECTRIC
SWITCH and FRICTION BRAKE

ADJUSTMENTS

DETAILED VIEW OF THE
AUTOMATIC SWITCH
AND BRAKE.

(1) If the latch does not trip, or trips before completion of a record, bend the hand-lever stop slightly to the right or left, as necessary.

(2) If the latch trip does not engage correctly with the latch-plate, loosen the two latch-plate screws and shift the plate one way or the other, as necessary. Re-tighten the screws. Remove any burrs from the teeth of the latch plate with fine emery paper.

(3) If the electric switch does not make and break contact when the hand-lever is turned on and off, it may be necessary to bend the long contact spring, or loosen the two switch screws and move the switch until the correct position is found. In the off position, there should be at least $\frac{1}{8}$ " gap between the contact points.

PHONOGRAPH PICKUP

ATWATER KENT MFG. CO.

**PHONOGRAPH PICKUP AND INDUCTION DISC MOTOR
(USED IN MODELS 75 AND 89-P)**

ELECTRICAL CONNECTIONS OF PICK-UP, VOLUME CONTROL AND INPUT TRANSFORMER.

**INDUCTION DISC
PHONOGRAPH MOTOR**

ELECTRICAL CONNECTIONS OF THE INDUCTION-DISC PHONOGRAPH MOTOR.

The induction-disc phonograph motor has two sets of field coils or "inductors." Each inductor has three coils and five "poles." A magnetic field is produced between the poles by the alternating current flowing through the three coils.

The edge of a non-magnetic rotor disc fits in the narrow gap between the poles on each inductor. The magnetic field between the poles causes the disc to rotate.

The rotor disc itself has no coils, and there are no electrical connections to it.

The speed of the rotor disc is controlled by a governor and a regulating screw device. The correct speed is 78 revolutions per minute (with pick-up on record). The speed may be determined by counting the number of revolutions made by the turntable in one minute. It is preferable,

BOTTOM VIEW OF MOTOR BOARD.

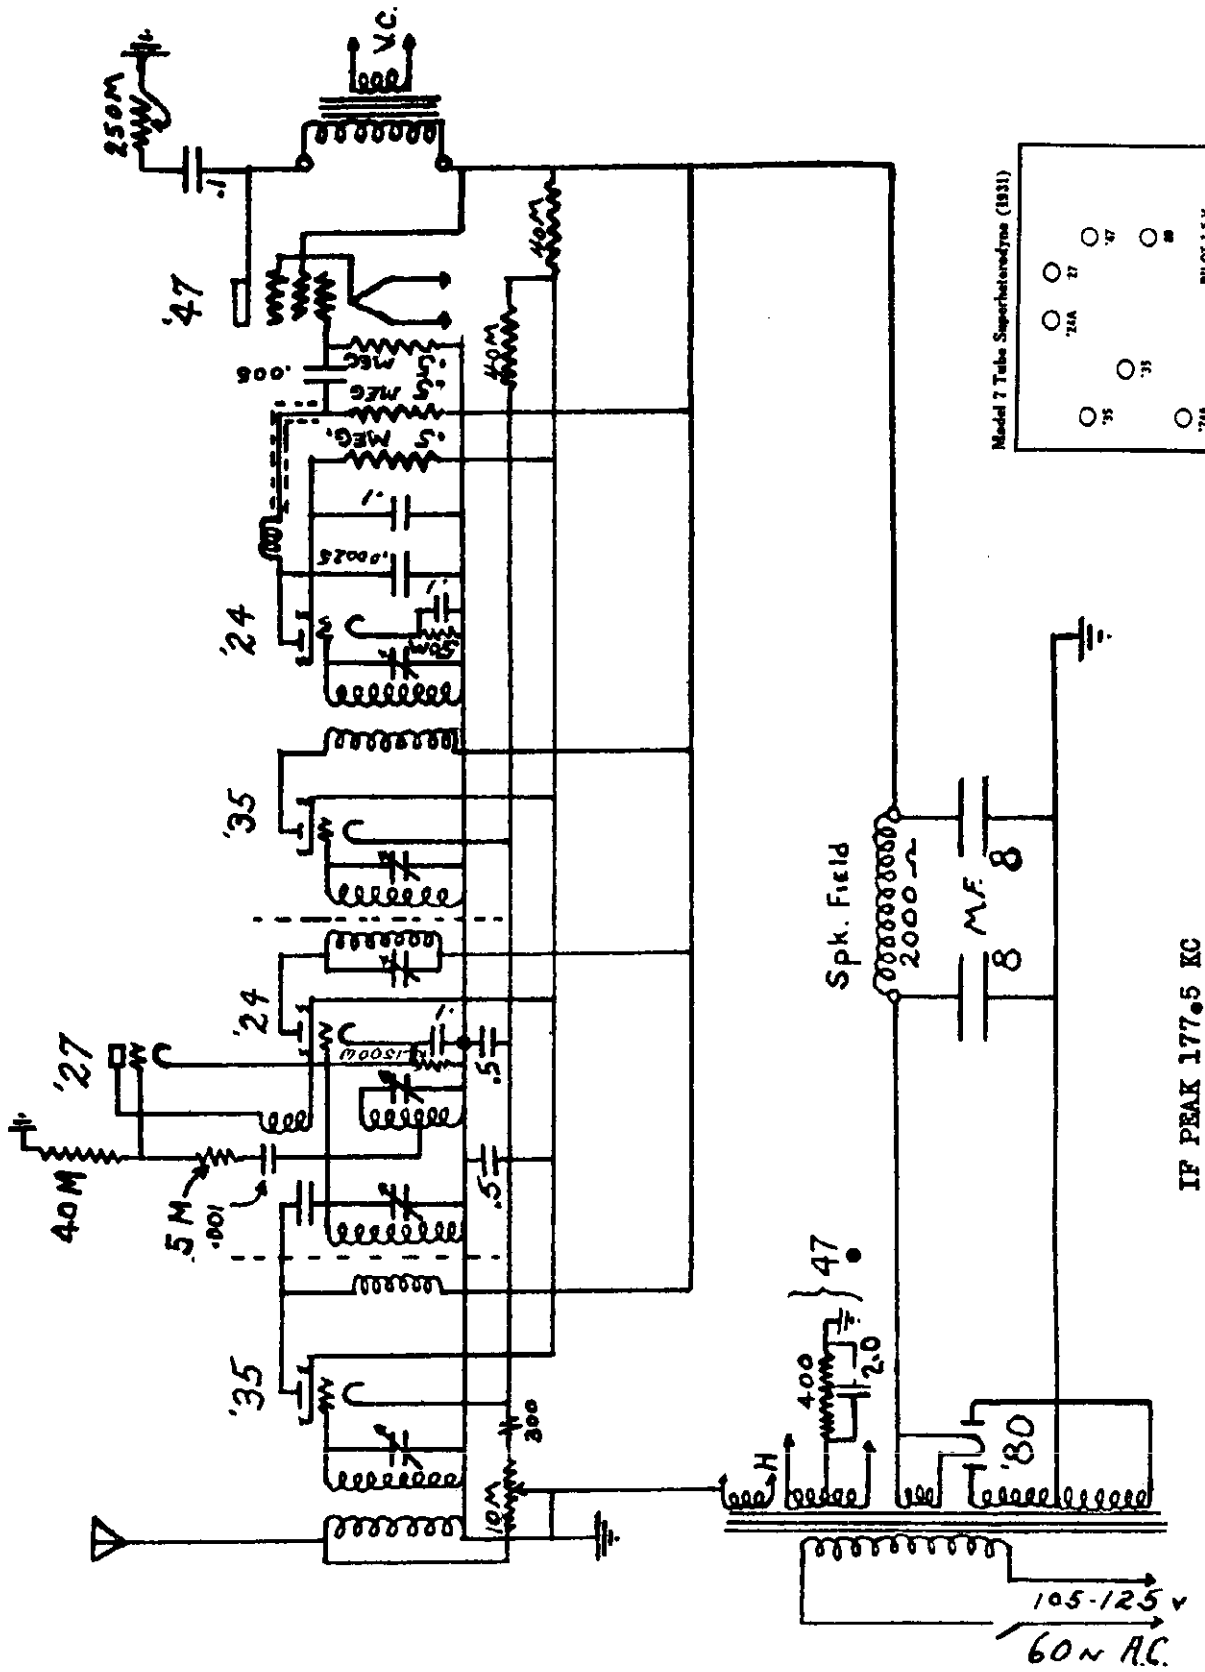

however, to regulate the speed with the aid of a stroboscope disc, which may be purchased from your distributor. Simple instructions for the use of this inexpensive device are printed on the back of the stroboscope disc. The speed should be checked at least twice a year.

The motor and governor bearings and gears must be kept well greased at all times. See chart on bottom of motor board.

When an induction-disc motor requires repair, it is advisable to tear it down completely, replace the defective parts, clean and grease all parts, and reassemble correctly.

Service Notes

4. After adjusting the third I. F. transformer shift the coupling lead to the control grid connection of the first I. F. tube and place the lead at a greater distance from the oscillator. Be sure the shields are on all tubes except that to which the coupling lead is connected. Turn the volume control up slightly and in exactly the same manner adjust the secondary and primary of the second I. F. transformer until a maximum indication is obtained. The output must be kept low enough to give a sharp peak.

5. Clip the coupling lead on to the control grid cap of the first detector tube, replacing all other shields and proceed to peak the secondary and primary of the first I. F. transformer. If the set oscillates it is due to the coupling lead being connected to the grid of the first detector and the volume control should be slightly reduced to prevent oscillation. Now with a given indication on the output meter proceed to "touch up" all of the adjusted trimming condensers to take advantage of any slight increase in reading that might be obtained by more careful peaking, and after they are all correctly balanced lock them by holding with the nut wrench and tightening the set screw with a long screw driver. The insertion of the metallic screw driver will affect the reading of the output meter but it should return to normal when the screw driver is removed. Note carefully that the locking does not throw the stage out of alignment. It may be easier for the service man who is not familiar with this operation to slightly reduce the capacity of the trimming condenser and lock the screw down fairly tight and then after removing the screw driver, slowly bring the unit up to its peak reading. This may be found difficult at first but with a little experience the I. F. stages can be rapidly balanced.

6. Now set the test oscillator in operation at exactly 1400 KC, place the set in normal operation and replace the oscillator tube and all shields. Make sure the receiver is properly grounded and has an average antenna. Set the local-distance switch in the distance position thereby connecting the antenna. Couple the test oscillator to the antenna by means of its coupling lead. Locate the 600 KC oscillator trimming condenser and turn it nearly all the way in, about one-half revolution from full in.

7. Tune in the 1400 KC signal, adjusting the volume control to give a good indication on the output meter, then adjust the tuning knob until the scale reads 1400 KC. Now adjust the 1400 KC oscillator trimming condenser (on the oscillator section of the four gang condenser), the first detector, R. F. and pre-selector circuit trimming condensers in the order given until maximum output is obtained. The oscillator section of the gang condenser is the second section from the dial. When the set is not in a cabinet the location of a pointer for dial calibration is determined at maximum capacity of the condensers by a line provided at the low frequency end of the tuning scale.

8. Tune the test oscillator to exactly 600 KC. Tune in the signal on the set and adjust the 600 KC oscillator trimming condenser for maximum output on the output meter while revolving the gang condenser back and forth, by rotating the tuning knob.

9. Set the test oscillator frequency to 1400 KC and set the selector scale at exactly 1400 KC. Adjust the four trimming condensers as in No. 7 in the order given until maximum output is obtained.

10. Place the test oscillator again in operation at 600 KC and tune in the signal and if adjustments have been properly made the signal will be received at maximum output when the scale reads exactly 600 KC. If not the operations described above must be repeated.

11. Now lock all trimmers as described in the instructions for locking the intermediate frequency trimmers (paragraph 5) while carefully watching the output meter to make sure that the locking action does not throw the stage out of alignment.

SERVICE NOTES

A. There are ten tuned circuits, all of which must be in accurate adjustment in order to allow this receiver to operate at its maximum efficiency. These adjustments are made by means of eleven trimming condensers which are carefully set and locked at the factory and should need no further attention provided they are not tampered with. These condensers are all of the compression type and are adjusted by the rotation of the long nut and locked by means of a hardened steel set screw. The service man should delicately attempt rotation of these nuts with a special nut wrench to determine if they are loose, and if all are tight and locked they should never be touched unless it is definitely assured that the set is out of alignment after every other service possibility has been exhausted.

A piece of thin fiber tubing about 7" long and with $\frac{1}{4}$ " bore which can be supplied by us for this purpose may form the nut wrench. The locking screw driver should be long and thin enough to slip down thru the fiber tubing and lock the set screw, while the nut is held from turning by the tubing wrench.

By inspection of the service wiring diagram it will be noted that there are six capacity adjustments, one on each primary and one on each secondary of the three intermediate-frequency transformers. These condensers resonate the tuned circuits of the intermediate-frequency amplifier to exactly 175 KC. There are also four trimming condensers, one on each section of the four gang variable condenser. The three trimming condensers associated with the pre-selector, R. F. and detector stages balance these three stages to resonance while the fourth trimming condenser, which is on the oscillator section of the four gang variable condenser, forms part of the network which adjusts the oscillator to its constant frequency difference of 175 KC. There is also another oscillator trimming-condenser located next to the last section of the four gang tuning condenser and adjacent to the first detector tube. In some chassis this is reached thru a hole in the top of the condenser gang near the front and in others thru a hole in the chassis in front of the dial. This condenser is called the 600 KC oscillator trimming condenser, while the one on the oscillator section of the tuning condenser gang is the 1400 KC oscillator trimming condenser.

In order to adjust all of these trimming condensers properly it is necessary that an R. F. oscillator giving a modulated signal at exactly 1400 KC and 600 KC, and also at 175 KC be secured. An output measuring instrument is also necessary. The General Radio Company type 360-A or Radio Products Co., Dayton, Ohio, HR 180 test oscillators are suitable for this purpose.

The output meter leads should be connected across the cone coil connections of the loud speaker. The cone coil may remain connected or be disconnected, satisfactory results being obtained in either case, altho if the cone is left connected an audible check on the instrument readings is obtained.

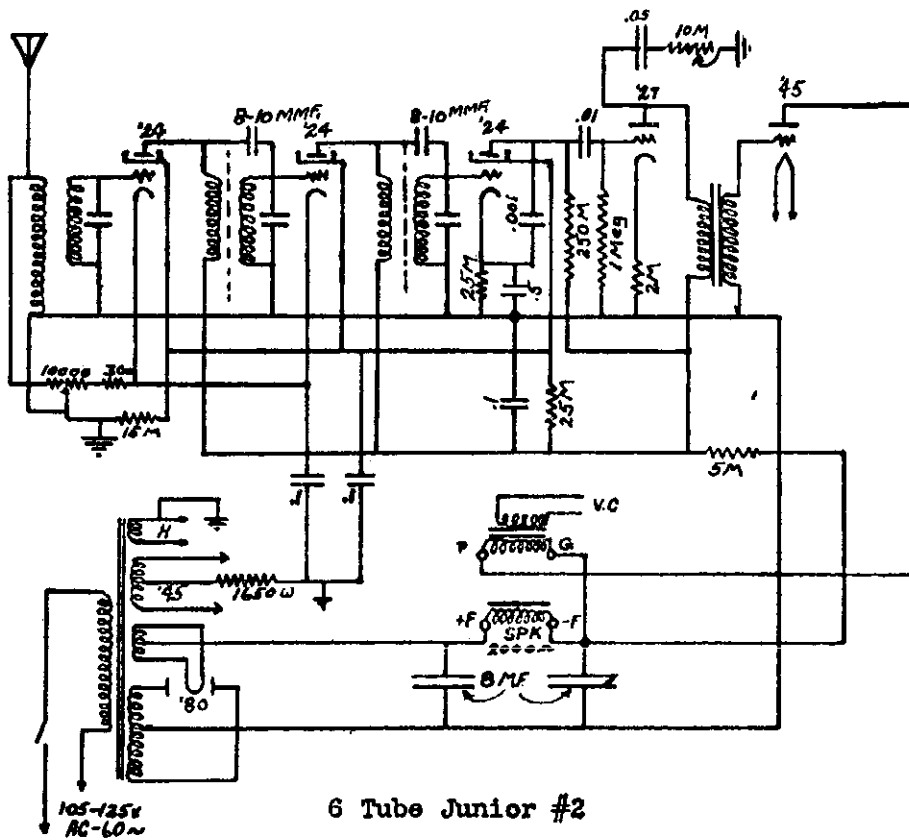

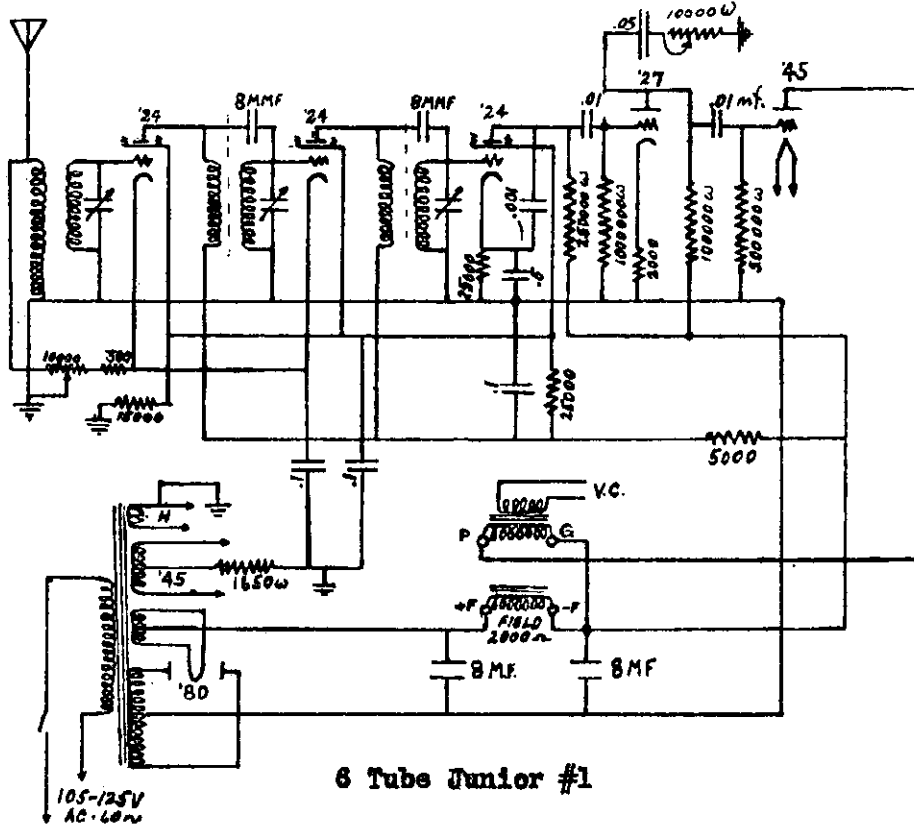

The receiver must be balanced from back to front or left to right, that is, the last I. F. transformer is adjusted first, then the next to last I. F. transformer, etc., working backwards thru the first detector, oscillator, R. F. and pre-selector.

The following procedure should be followed:

3. Adjust the secondary and then the primary trimming condenser of the last I. F. transformer until a maximum reading is obtained on the output meter. These two circuits must be accurately peaked to 175 KC and will be found quite sharp.

* Readings will vary according to resistance of meter. Tubes used in this test are average tubes.

METHOD OF ALIGNING R.F. CIRCUITS

In the event the antenna and first detector tuned circuits are out of alignment, they may be adjusted with the aid of a weak high frequency (1300 to 1500 K. C.) signal—produced by a distant station or a local test oscillator. Tune this signal in very carefully for maximum volume, or better still, if one is available, for maximum deflection on an output meter. Adjust the antenna tuned circuit adjustment screw (located near the type 47 tube on the top plate of the turret condenser) for maximum volume or for maximum deflection on an output meter. Then, without changing the position of the tuning knob, adjust the first detector adjustment screw—located adjacent to the A. C. switch—for maximum volume or maximum deflection on an output meter. Before tightening the lock unit on each adjustment screw, go over the adjustments a second time to secure the greatest possible accuracy. A drop of ambroid glue or collodian should be placed on each adjustment screw after the lock nut has been tightened to prevent handling and speaker vibrations from changing the adjustment.

In most cases it will be unnecessary to touch the oscillator adjustment screw (located between the antenna and first detector adjustment screws.) If this adjustment is necessary it is recommended that the intermediate frequency transformer circuits be tuned first (see following paragraph). Then tune oscillator circuit, employing same method as explained above for antenna tuned circuit and first detector circuit. In the event any circuit does not tune properly, check the circuit thoroughly for open and short circuits. If the trouble cannot be located, the coil should be replaced with a new one.

METHOD OF ALIGNING I.F. TRANSFORMERS

In the event the receiver is still insensitive and lacks proper selectivity after making the foregoing adjustments, the intermediate frequency transformers should be adjusted by one of the following methods:

1. Tuning Intermediate Transformers with 175 K.C. Oscillator

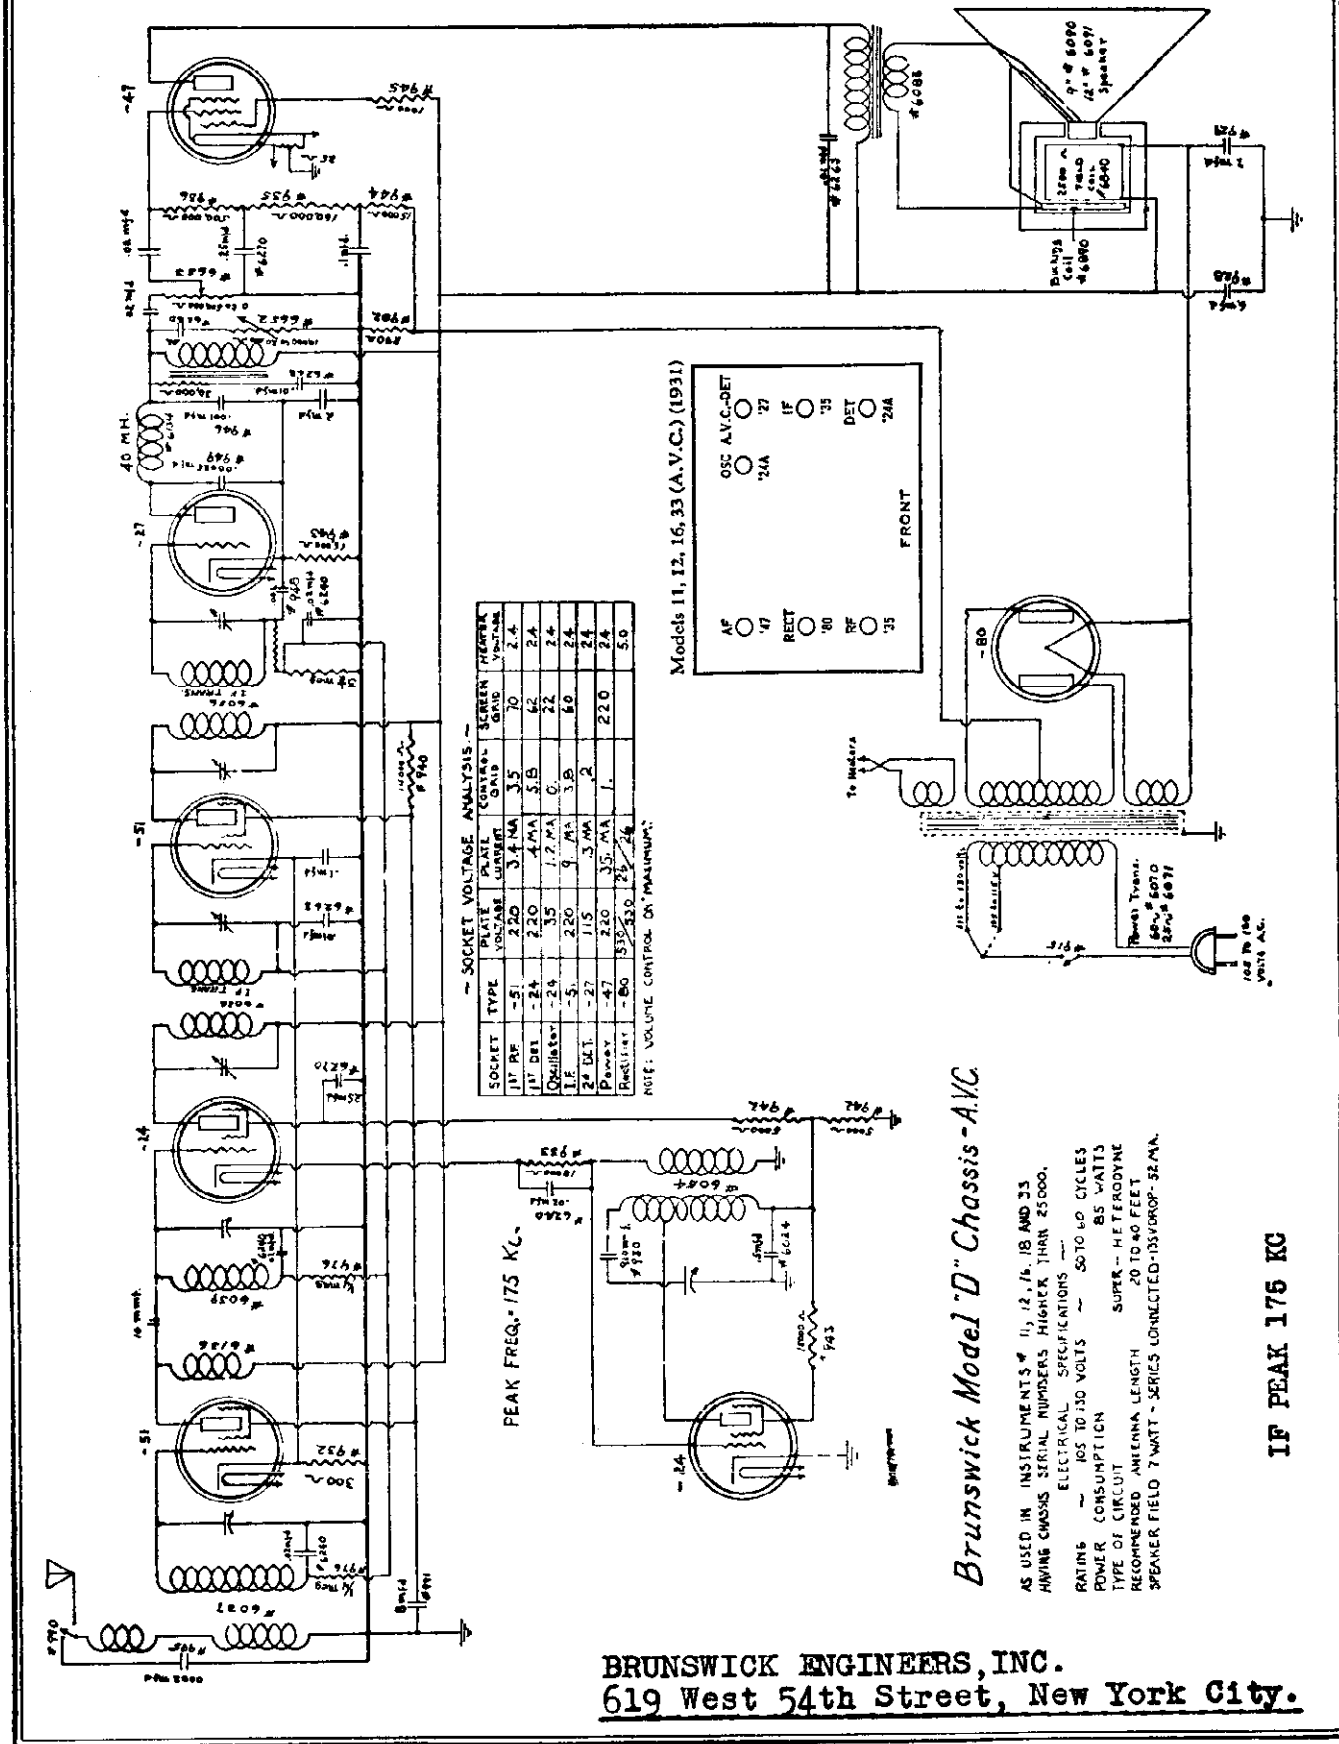

By far the best method of aligning the tuned circuits in the intermediate frequency transformers is to employ a 175 K.C. oscillator and output meter. In making this test, remove the oscillator tube and connect the output of the oscillator to the grid cap of the first detector. Usually it will not be necessary to remove the grid cap from the tube, this depending on the strength of the oscillator and the amount the I.F. transformers are out of line. Connect the output meter across the primary of the output transformer located on the speaker (terminals 3 and 7 counting from left to right). The four I.F. adjustment screws on the I.F. transformers, located inside the chassis, should be adjusted with a non-metallic screw driver for maximum deflection on the output meter. Go over all four adjustments a second time to secure maximum accuracy.

2. Tuning Intermediate Transformers without 175 K.C. Oscillator

In the event a 175 K.C. oscillator is not available a fairly close adjustment may be made by tuning in a faint broadcast signal, and with the volume control turned on full, adjust the transformers for maximum volume with a non-metallic screw driver. After adjusting the I.F. transformers, the R.F. circuits should be realigned as explained before.

VOLTAGE READINGS AT SOCKETS

Socket	Tube	Type	Filament	Grid	Plate
#1	1st R.F.	UX-201-A	5.5	-9	80
#2	2nd R.F.	" "	5.	-9	80
#3	3rd R.F.	" "	5.25	-5	80
#4	Detector	" "	5.25	0	32
#5	1st Audio	" "	5.75	-9	88
#6	Power Stage	UX-171-A	5.	-24	96
#7	" "	" "	5.	-15	88
#8	" "	" "	4.3	-15	92
#9	" "	" "	4.3	-22½	96

These readings will hold within 10% when taken with any reliable make of set analyzer with the tube in the socket of the set analyzer, the line voltage at 120 volts, and the volume control on maximum. Filament voltage will vary with different tubes because their filament resistance varies.

METHOD OF ADJUSTING NEUTRALIZING CONDENSERS.

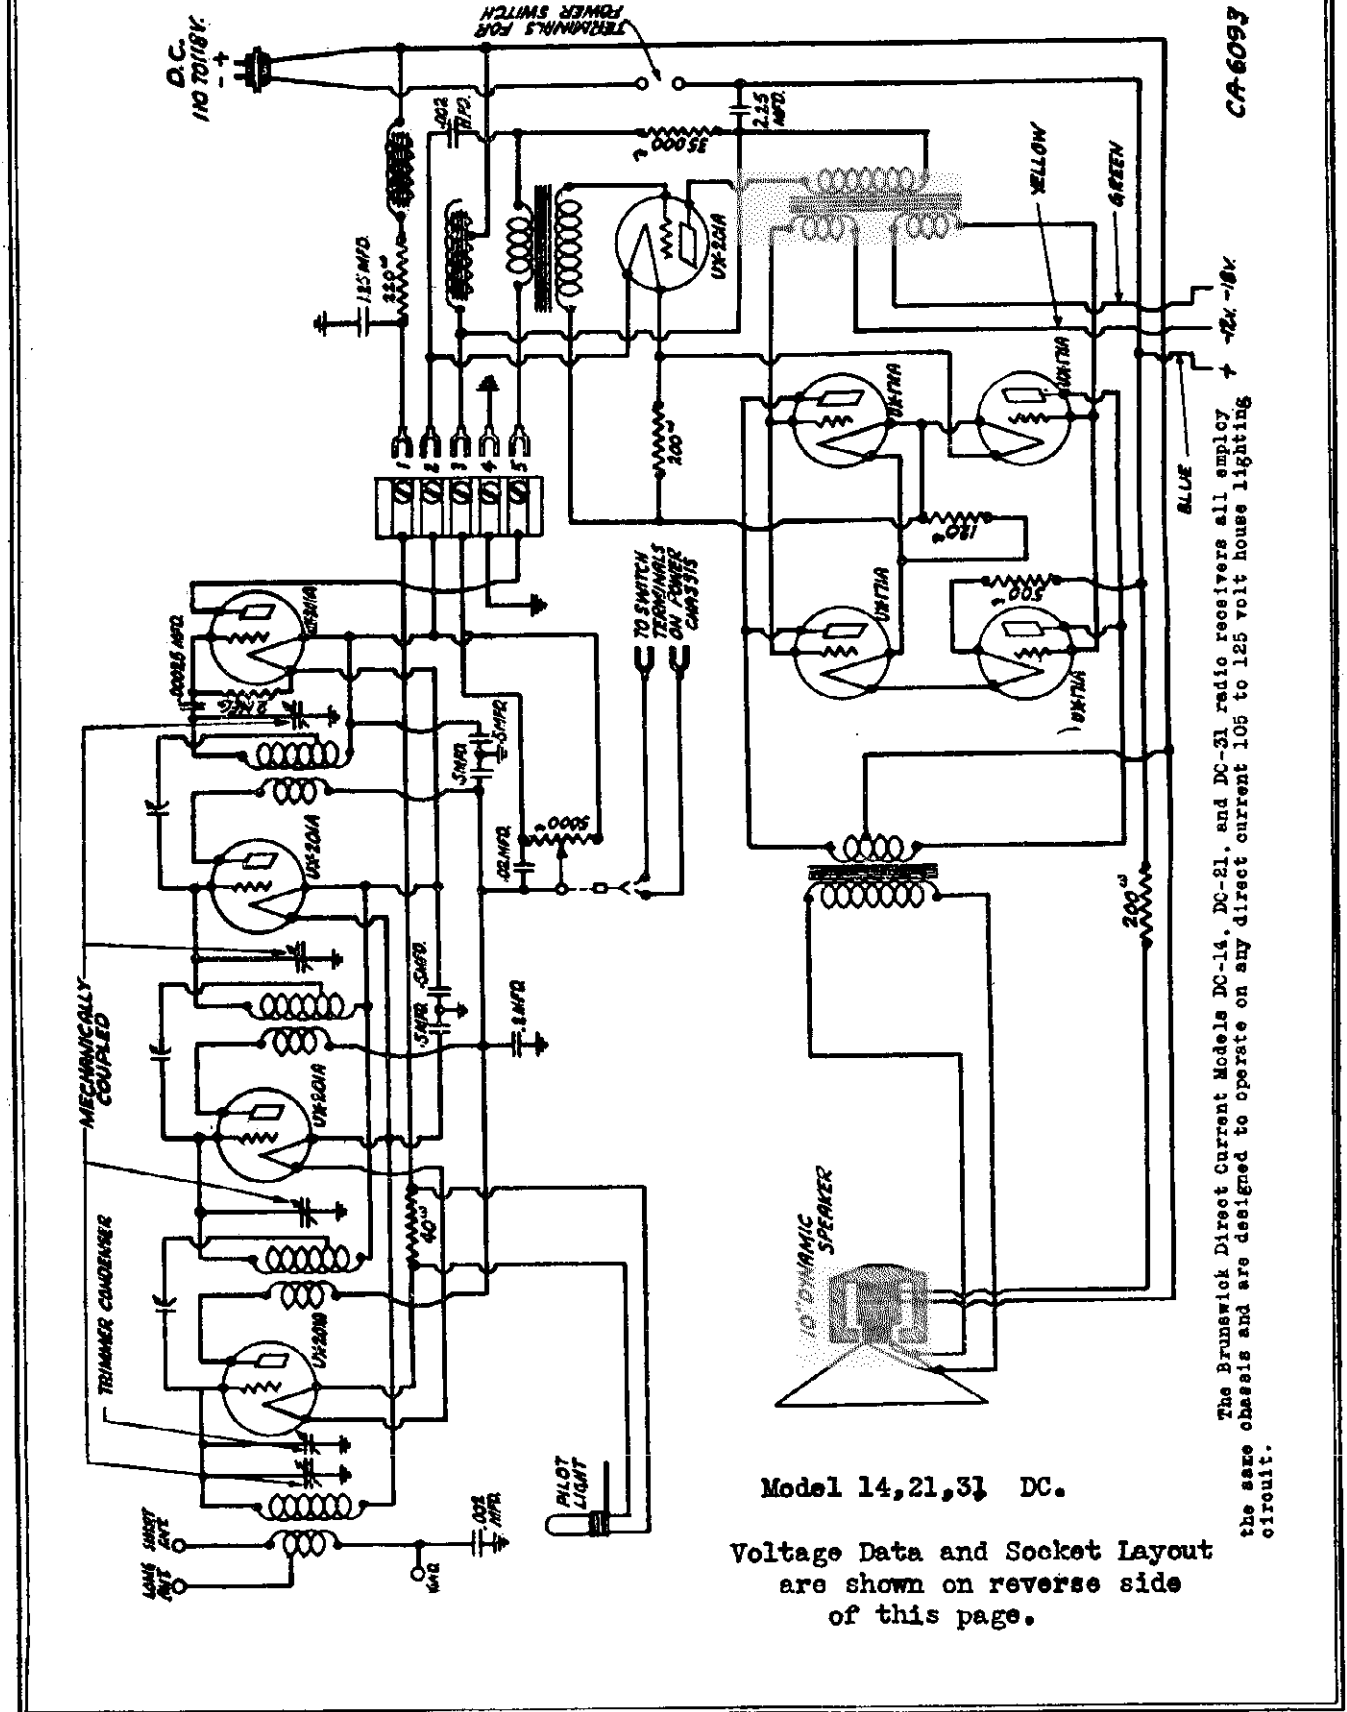

In the event the receiver oscillates at any or all parts of the tuning range, the ground and antenna should be inspected to be sure there is not a poor connection at some point. If the oscillation still persists, try changing the tubes around, and if this does not eliminate the trouble, the receiver should be neutralized by the following method:

Select a good UX-201-A tube of the same make that is to be used in the receiver and cut off one filament prong close to the base. Because the filaments of all tubes are connected in series, it will be necessary to connect a 1.25 ohm resistor across the filament contacts of the socket in which the dummy tube is to be used. (The filament of another tube may be used for this purpose.) Tune the receiver to a powerful local station broadcasting on a frequency of between 1000 and 1500 kilocycles, and adjust volume control and antenna trimmer condenser for maximum volume. Insert the dummy tube in the first socket and connect the resistor or tube filament across the filament circuit - the first neutralizing condenser should now be adjusted until no sound, or the minimum sound, is heard in the reproducer. Adjust the other two stages in the same manner and the receiver is neutralized.

In the event the receiver cannot be neutralized the R.F. by-pass condensers should be tested for open circuits and a different dummy tube should be tried.

INTRODUCTION

The Brunswick Model 42 Automatic incorporates the same armored chassis and dynamic speaker that is used in the Models 15 and 22. In addition it has the added feature of the Automatic Panatrope which will play twenty records without attention, and then shut itself off. It is the purpose of this bulletin to show only those features which deal with the Automatic equipment, its connections to the radio chassis, and also the information dealing with coin operation. All other data on the radio set can be obtained from Service Bulletin No. 71.

The operation of the Automatic Panatrope is extremely simple, as will be readily seen by the following explanation:

Figures 1 and 2 show top and front views of the Model 42 and indicate the various components that enter into its use.

With the station selector control turned past the 1500 K. C. mark, and twenty or less records in the record magazine, turn the

SECRET 7

Fig. 1

"off" and "on" switch to the "on" position. Then press the "start" button. This will do the following: connect the power to the radio chassis so that the audio amplifier can be used for record reproduction; starts the motor and automatic mechanism for the cycles of playing the record and ejecting the played record into the reject compartment.

Fig. 2

PART II
THE STORY OF THE AUTOMATIC AND ITS OPERATION THROUGH A COMPLETE CYCLE

The accompanying series of sketches have been prepared in order to present a clear idea of the cycle of operations through which the Automatic mechanism goes during the playing, the rejection of a record, and the starting of a new record. In conjunction with the following explanation, these sketches should make what appears to be a complicated mechanism really a very simple piece of apparatus. An automatic record playing instrument may be made in innumerable ways, but the simplicity of its mechanism reflects the true engineering skill behind it. There should be no more apparatus necessary than that required to accomplish the purpose of the machine. In servicing such a machine, this is a factor to be appreciated.

In Sketch 1 the record is shown in the playing position. As the magnetic pickup moves toward the center of the record, beneath the top plate of the mechanism the suspension arm is pulling a special switch with it. This is shown in Sketch 2. When the end of the record is reached, this switch hits against an adjustable stop, closing the switch contacts.

From this point on, many things occur in a short space of time, ten seconds or less. Reference to the schematic circuit appearing in Figure 6 will also help to clear up a few points. In fact, it will more than pay the person who meets up with this model to sit down and follow out this circuit along with this description.

The switch just mentioned is designated as the "Suspension Arm Switch" in the schematic circuit. When this closes, the line voltage is placed directly across the solenoid coil, also shown in Sketch 3. Immediately the solenoid armature pulls the stop lever from the dotted line to the solid line position. The projection "F" on this lever (follow to Sketch 4) moves out of the way of the clutch pawl, allowing the latter under the tension of the small spring to slip in and engage with the teeth of the clutch. The only revolving parts up to now have been the motor, ejector friction disc, and the turntable. Sketch 5 shows the parts which start revolving when the clutch engages. A little further on, the reason for these gears will become evident.

As the master gear revolves, three cams on its under side function. The first is shown in Sketch 6, operating the cycle switch. This switch, closes (refer to schematic circuit and

MODEL 42
AC-DC
BRUNSWICK RADIO CORP.

steadily. The oil holes are located directly beneath the turntable. A few drops will suffice; do not flood the motor with oil as this can do more harm than good.

The Brunswick Permo-Point needle, which accompanies each instrument, will play in excess of 2,000 records. It is recommended that this needle be used in preference to all other types.

Some of the simple adjustments which may be necessary to accommodate slight differences in records, as well as some suggestions to take care of possible changes caused by shipment, are given below.

We recommend that the first time any of these adjustments are made, that the plate covering the mechanism be removed. This can be accomplished as follows:

- (a) Lift off the turntable.
- (b) Remove all screws around the edge of plate covering mechanism, as well as those around the suspension arm.
- (c) Remove the nut which holds the suspension arm to the cast iron base.
- (d) Carefully lift up the suspension arm about three-quarters of an inch and remove the plate by pulling up the front end and gently lifting out—taking care not to mar the cabinet. Removing this plate will bring the mechanism into view, permitting the adjustment of four primary points.

1. Adjustment determining the point at which the magnetic pickup is lowered to edge of record.

Replace the turntable, re-tighten suspension arm nut, and place a record in the record magazine; press the start button. As the master gear starts through the last half revolution (see Sketch 8) it will be seen that the eccentric stop "s" controls the release of the lever "w," which is pulling the suspension arm toward the record. The adjustment of this "stop" allows the needle of the magnetic pickup to drop on the edge of the record about a sixteenth of an inch from the grooves.

2. Also in Sketch No. 8 there will be seen a spring, "q."

After the needle has come in contact with the record, this spring pulls the suspension arm over until the needle rides in the starting grooves of the record. If the spring tension be too great, the needle may jump several grooves, or on the other hand, if it is too weak, will not pull the needle into the starting grooves at all. The earlier models with serial numbers up to 2,000 have this spring attached to a fixed stud and the tension can be varied by shortening or stretching the spring. Those with serial numbers above this have an adjustable bracket to which the spring is attached, permitting the tension to be varied without touching the spring. The remedy is obvious.

3. At the base of the suspension arm, see Sketch No. 2, is a switch which controls the rejection of a record at the finish of its playing. There are two types of these switches, the earlier type—on models with serial numbers less than 2,000 (this type is shown on the actual wiring diagram Figure 5)—and the later one that is indicated in Sketch 2.

Removing the cover, the action of this switch can be observed. As the record plays, the switch casting is slowly carried along with the suspension arm. In the earlier type of switch the floating contact member does not touch either side contact until the magnetic pickup reaches either the inside groove of a concentric grooved record where a stop (see Sketch 2) causes the left contact to close; or on an eccentric grooved record will cause the right contact to be closed. If either of these two contacts are too close to the floating contact there is a possibility of the record rejecting before it is finished. Also, if the separation from the right

note that the "reset" and "off-on" switches are closed) in order to maintain a closed power circuit to the motor when the "reset" switch opens a little later. Immediately thereafter, the second cam on the master gear, not shown, has revolved to a position where it actuates a lever raising the pickup arm, see Sketch 6.

Referring to Sketch 7—with the pickup raised off the record, the third cam raises the ejector wheel to a position where the friction cone rides on the ejector friction disc. As the ejector wheel comes up and starts to revolve, it also brings up the push rod opening the "reset" switch (see schematic). The revolving ejector wheel sends the finished record out into the reject record compartment.

In Sketch 8, note the lever arm marked "t." Functioning through its mechanical connection to the master gear, it starts moving the pickup suspension arm out of the way of the next record coming down from the magazine. The levers "x" and "y" are also working at the same time and through the connecting rod "z," as the pickup moves to the right, sends a new record down to the turntable. Sketches 8 and 9 show the respective positions of the mechanism and top of the Automatic Panatropes at the middle of the record change operation. The master gear only revolves once. The reasons for the two reduction gears, Sketch 5, should now be apparent; namely, because the turntable shaft revolves at 78 R.P.M., and this speed is entirely too high for direct application to the other moving parts, suspension arm, etc. Even if it were, the size of the motor would have to be much greater to supply all the power required during the record change. The gears serve to keep the power consumption of the Panatropes down to a minimum.

When the new record drops on the turntable, it hits the push rod closing the "reset" switch, thus keeping the power circuit to the motor and chassis closed even though the cycle switch is still closed. The position of the record, ejector wheel and push rod are now shown by Sketch 10.

Going back to Sketch 8, the suspension arm return lever, "w," now comes into play. This is during the last half of the master gear revolution. As the master gear returns to its original position, the suspension arm return lever, "w," catches the projecting pin that was pushed over by "t," carrying the suspension arm back until the other end of "w" hits the stud "s." This releases the pin, leaving the suspension arm and pickup in position over the first grooves of the new record. With the return of the suspension arm, the arm "v" in the record magazine has moved back ready to advance the next record. The pickup is lowered to the record and the master gear, completing its cycle, allows the stop lever arm to drop to the position indicated by the solid lines of Sketch 11 under the tension of the spring "u." The projection "r," Sketch 3, engages the clutch pawl, preventing the gears from revolving further. The cycle switch opens and the new record continues the program.

There is one more point to consider. Had the record magazine been empty, the mechanism would have worked in the same manner with one exception, the push rod would have remained up and the "reset" switch open. From the schematic circuit, it is evident that upon the opening of the cycle switch, the power supply circuit is broken and the whole machine shuts off.

PART III
ADJUSTMENT AND CARE

All initial adjustments are made at the factory so that the instrument is ready for immediate use when properly installed. The turntable speed should be 78 R.P.M., but if for any reason it is thought that this speed is not being maintained, by placing a paper clip at some point on the record's edge for an indicator and timing the turntable, it is possible to check this. The motor speed control is directly above the motor and is readily located when the cabinet back is removed.

The motor should be oiled about once a month; a little oftener if the machine is used

MODEL 42
AC-DC

BRUNSWICK RADIO CORP.

Figure 4

Figure 3

**MODEL 42
AC-DC**

BRUNSWICK RADIO CORP.

contact is too great, the switch will not close on an eccentrically grooved record. If the stop for the concentric grooved record is set too far to the left the contact will not close, and if set too far to the right, the record is rejected before the selection finishes.

The later type of switch has been simplified somewhat in construction, having only one contact, but accomplishes the same work. If the previous discussion has been carefully followed, similar reasoning applies to the adjustment and operation of this later type of switch. On the models with this later type switch the "stop" previously mentioned is adjustable through a hole in the plate covering the mechanism.

4. **Solenoid operation:**
Remove the turntable and press the start button. This energizes the solenoid coil which in turn operates the lever, which starts the functioning of the record-changing mechanism. After the record-changing mechanism completes its cycle, the electrical circuit of the solenoid is opened and it is de-energized. The spring, "u," sketch 11, pulls the lever into its normal position. If the solenoid for any reason does not draw the armature in properly or the armature vibrates against the solenoid, it can be adjusted by means of the two screws which mount the solenoid to the base. Also, if the spring "u" is too weak, the record-changing mechanism will not stop, but will continue to reject the records. If too strong, the solenoid will not have sufficient power to operate the record-changing mechanism. The solenoid armature is hollow and contains a rubber bumper which dampens out alternating current vibrations.

GENERAL POINTS TO CHECK UP IF THE AUTOMATIC PANATROPE IS INOPERATIVE

1. Be sure that the power line plug is connected to the receptacle and that this is "alive." The latter can be readily determined by plugging in a floor lamp or other similar electrical device.
 2. The power plug joining the Automatic mechanism and radio chassis should be solidly connected.
 3. The Panatrope input transformer tip leads should be well seated in the tip jacks at the rear of the radio chassis.
 4. There should be not more than twenty records in the magazine and reject record compartment at one time to prevent the possibility of jamming and record breakage.
 5. The "Off-On" switch on the Panatrope control panel should be placed at the "On" position, and the volume control turned up far enough to insure sufficient volume.
 6. The station selector scale should be turned past the 1500 K. C. mark until the clicks of the Radio-Panatrope change-over switches are heard.
 7. By pressing the "start" button for an instant, the radio tuning scale should be illuminated and the turntable set in motion. If the latter revolves, but the scale is not illuminated, the fuses under the power transformer cover should be tested and any defective ones replaced. Check the pilot light for continuity if the radio tubes light up.
 8. If everything checks up to this point, and still no reproduction is obtained, see that the group of three tubes at the left of the radio chassis (when viewed from the rear) are lighted. Remove the cover on the three screen-grid tubes and replace the tube nearest the rear of the chassis with one known to be okay.
 9. For pick-up trouble see Service Bulletin No. 70, page 9.
- In conjunction with the following possibilities of trouble and their remedies, it would be well for the one contemplating service on the instrument to stop for a moment before

**WIRING DIAGRAM - MODEL 42 - AUTOMATIC
CA - 7011**

Figure 5

MODEL
AC-10

BRUNSWICK RADIO CORP.

delving into the machine and try to analyze the cause of the trouble. This will save much time and unnecessary work.

Records Jamming in Mechanism

There are several conditions which may cause this; the most likely are those due to (a) warped records, (b) the record feed fingers on the record magazine bent, (c) the spring on the record gate (which supports the records while stored in the magazine) adjusted too closely, allowing only thin records to pass through; or the other extreme, too wide, allowing two records to go through, (d) the space under the record feed fingers allows two records to be caught instead of a single one.

Obviously, for (a) the record should be placed on a warm flat surface until it is once more flat. For (b) it will be necessary to remove the mechanism from the cabinet (see paragraph headed "Removal of Mechanism from Cabinet") to get at the small spring which provides tension for this finger. After once seeing how this particular part functions, the average service man can effect the repair by running the mechanism to the middle of a cycle, at which point the record feed finger will be at the edge of the magazine. If the spring is broken and enough remains to permit stretching it, too much tension will not be a serious drawback on the finger; otherwise, it is necessary to replace the spring with a similar one. For (c) refer to Figure 1. This shows the record gate in question, situated immediately over the center of the record on the turntable. This has a spring clip at its center which is adjustable either up or down. To adjust for two records coming through at once, lower the gate, and for a single thick record raise it. If records of standard make, and not warped, are used, very little trouble will be experienced from this point after it is once set. In a few cases (d) it has been found that the space under the record feed finger of the magazine lever permits two records to be caught at once. Should this be the case, the part of the lever which goes under the record first can be raised a small amount, thus lowering the height of the finger when it comes forward to select the next record for reproduction. In case the turntable does not revolve after these troubles have been remedied, turn the motor governor by hand until the mechanism reaches the start position; then it will run as usual.

Adjustment of Feeder Rod

The feeder rod is located at the back of the automatic mechanism, and is made accessible by removing the wooden top cover around the record magazine. Also refer to Sketch 9. Its length controls the distance through which the magazine lever moves. This does not often need attention but can be changed in length as follows: Loosen the lock nuts at either end of the rod. To shorten, turn the rod in a clockwise direction, or in case the rod is to be lengthened, turn in a counter-clockwise direction. Then tighten the lock nuts.

Record Ejector Wheel Not Functioning Properly

Sometimes the record ejector wheel will come up but fail to turn and throw the record out. This may be due to neglect in oiling the shaft to which it is attached. As this is only a friction drive, any opposition to its turning, in addition to the ejection of the record, may be detrimental. Other possibilities are that the friction cone is covered with oil, or is worn down. Clean it off and check before going further. If it has worn down, check the spring in the plunger which pushes this wheel up. See that this spring has some life in it by noting whether the ejector wheel rebounds readily when pushed down. If, after this the trouble is not obvious, try placing a very thin washer behind the friction cone to move it forward a little or replace the cone.

Solenoid Trouble

Vibration during record changing cycle. This may be due to the solenoid being improperly centered, or caused by the rubber bumper in the hollow solenoid armature not functioning properly. Loosen the screws which hold the solenoid to the iron base, and push it forward.

action by operating it with the finger. It is absolutely essential that the armature be properly centered. It may even be necessary to place a small piece of paper beneath the bracket near either of the two screws, or one side of the bracket to center it, but be sure it is finally centered. If the solenoid rattles after this, take the armature out and determine whether the rubber has lost its elasticity, due to excessive heat or moisture. If so, replace it and center the solenoid again. Also see "Solenoid Operation" at beginning of Part III. For an open winding in the solenoid there is no alternative but to replace the coil.

Gear and Clutch Mechanism--Cycle Switch

This is the heart of the whole mechanism. Once properly set, the likelihood of its causing trouble is small. If for any reason it becomes necessary to remove the gears, the easiest way to reset the timing is to loosen the solenoid, set the solenoid stop lever (see Sketches 3 and 4) in a position such that it has the projection "r" directly over the slot in the clutch disc. To do this it will be necessary to unfasten the solenoid lever. Raise the master gear sufficiently to clear the intermediate gear and rotate it to a position such that the end of the stop lever is in position near the slot in the master gear. Lower the master gear so that it engages the intermediate gear cogs and then drop the stop lever into position. Set the stop lever snugly in place in the slot of the clutch disc. At this point, the clutch pawl is disengaged from the clutch. If this is not possible, raise the stop lever arm and master gear again and move the latter a single cog or two in the direction which will permit the stop lever to fit properly, then set the stop lever in place and fasten down the master gear by means of the nut under the base. It may be necessary to try this procedure several times before getting perfect operation, but once it has been successfully accomplished, it will be an easy point to tackle afterwards. In case it is found that the two gear segments on the intermediate gear have become loose within each other, this part should be replaced.

The cycle switch is shown in Sketch 6, and has only one moving contact. In the event this remains open circuited, the mechanism will stop just after the rejected record has left the turntable and before the next record drops down from the magazine.

Ejector Wheel Push Rod Assembly

The case may arise where the push rod does not come up high enough to open the reset switch. First, check this rod for bends by turning it around with the finger when it is in the upper position. If it is bent, carefully straighten the push rod and apply a slight amount of oil at the guide holes. The spring tension needs very little adjusting, and if the whole assembly is oiled once every six months, it should give no trouble. Also see latter part of paragraph under heading of "Record Ejector Wheel not Functioning Properly."

Removal of Mechanism From Cabinet

Whenever it is necessary to remove the entire mechanism from the cabinet, the following procedure should be followed:

1. Disconnect the instrument from the power line, and also open the power and Panatone plug connections between the radio chassis and the Automatic mechanism.
2. Four large nuts hold the mechanism in the cabinet, these being located at the four corners of the cast iron base. Remove these and the rubber cushions.
3. Remove the volume control knob on the control panel.
4. Remove the four screws that fasten the lid supports to the top cover of the cabinet, and gently lay the cover back.
5. Remove the wooden top piece which contains the "good" and "used" needle receptacles.

This exposes the entire mechanism and permits its removal from the cabinet.

**MODEL 42
AC-DC**

BRUNSWICK RADIO CORP.

- (b) Remove the rubber-covered record bumper from the top plate and also remove the rivet 9-16-inch above the record bumper hole.
- (c) Remove the rubber-covered adjustable record bumper and switch throw cam from the switch assembly supplied with the kit, so that the base plate may be used as a template.
- (d) Fasten the base plate of the switch to the under-side of the top plate (the switch should be mounted toward the outside edge of the top plate) using the two holes provided by the removal of the rubber-covered record bumper and the rivet (these two holes are referred to as "a" and "b" in the diagram).
- (e) Mark the location of the third hole (referred to as "c" in Figure No. 9) with a punch, remove the switch plate and drill this hole with a 11-64-inch or 3-16-inch drill.
- (f) The switch may now be assembled on the top plate.
- (g) Rotate the record bumper lever through its 180-degree arc several times and a 2 1/2-inch circle will be inscribed on the top plate. Turn the record bumper lever half way between its two end positions and mark the two places on the circle that are in line with holes "a" and "c." Use a 3-32-inch drill and drill at these two points two countersunk holes about 1/4 of the way through the top plate. These two holes serve as stop positions for the adjustable record bumper.
- 4. Connect Switch to Solenoid Circuit:
 - (a) Remove the black and brown leads from the right hand side of the solenoid and connect them to one of the switch leads. Connect the other switch lead to the solenoid terminal thus left vacant. This permits the operator (by turning the record bumper to the right) to disconnect the solenoid from the circuit so that the record-change mechanism will not function while a 12-inch record is being played.
- 5. Replace the Record-Change Mechanism in the Cabinet

- (e) From the dimensions given in Figure No. 9 Page 16, (see detail "b"), mark in pencil the exact shape of the cut to be made on the front record hopper support (note that only the front support is to be so cut). The important dimensions are the base line (1 1/2-inch above the turned in portion of the record hopper leg), the length of the base line (1 1/2-inch long as a minimum and 2-inch long as a maximum), the width of the cut at the front (1/2-inch to 1 inch wide) and the angle at which the top of the cut intersects the base line (the easiest way to draw this is to make the cut 1/2-inch deep at the inside).
- (b) Remove the two record-guide arms from the record hopper cross bar and remove the record hopper cross bar from the record hopper.
- (c) After marking the proposed shape of the cut on the front leg of the record hopper, as directed in paragraph "a" above, saw along the two horizontal lines with a back-saw until the inside vertical line is reached. Then bend the piece of metal to be removed back and forth until it breaks off. File the edges smooth.
- (d) File the protruding edges of the record hopper (indicated by "e" on the drawing) back at a 30-degree angle so that these points will not scratch the 12-inch records when they are placed on and removed from the turntable.
- (e) Fasten the record hopper cross bar and the two adjustable record guides (supplied with the kit) on the record hopper by means of the four machine screws and the two screw blocks (also supplied with the kit).
- 3. Fasten New Record Bumper and Switch Assembly to Top Plate:
 - (a) Remove the eight machine screws that fasten the right hand top plate to the record-change mechanism; the two machine screws that hold the suspension arm collar to the top plate and remove the top plate

- To Play 12-inch Records Manually:**
1. Turn station selector scale past the 1500 kilocycle mark until a click is heard and turn the "off-on" switch on the automatic panatrope control panel to the "on" position.
 2. Turn the two 10-inch record guide arms, located on opposite sides of the record hopper, up, and rotate the rubber-covered record bumper (located at the right of the turntable) toward the right-hand side of the cabinet as far as it will go, so as to allow 12-inch record to fit on turntable.
 3. Move the magnetic pickup toward the right-hand side of the cabinet as far as it will go and gently slide the 12-inch record on the turntable from the right side of the cabinet.
 4. The magnetic pickup can now be freely moved, and by placing it in the first playing groove of the record the 12-inch records can be played.
- To Change Back for 10-inch Record Automatic Operation:**
- Turn the record guide arms, located on the record hopper, down, and rotate the rubber-covered record bumper arm in toward the turntable. The instrument will now play 10-inch records automatically.

**PART IV
COIN OPERATION**

A coin operation kit has been made up, designated as Part No. 1000, for use in conjunction with the Automatic Panatrope mechanism. Full instructions accompany each kit showing the connections and physical locations of each part.

This equipment will permit the Panatrope to reproduce one record for each nickel inserted up to the capacity of the magazine—twenty records. The coin control device is actuated by the feeder rod at the back of the mechanism. If the machine is used exclusively for coin operation, the "Off-On" switch should be disconnected from the circuit behind the panel to prevent the whole magazine contents from playing on a single coin.

Connection to the circuit is extremely simple, as all that need be done is to separate the power plug from the chassis to mechanism and insert the extension plug provided with the apparatus. This layout and the connections are given in the accompanying diagram.

As this equipment is of rugged construction, it will give very little trouble. The most important point to check is to be sure the actuating lever is securely fastened to the protruding arm of the lever box. This lever normally assumes a vertical position and the ratchet wheel moves one notch with each record played. An improper placing of this lever results in either too much strain on it, or else it does not move the ratchet wheel.

Complete installation instructions are supplied with each coin operation kit which may be purchased from any Brunswick Distributor or Branch.

**PART V
12-INCH RECORD OPERATION**

Prior to Serial No. 2500 the Model 42 Automatic Panatrope with Radio was not provided with a means for playing 12-inch records. A demand on the part of music lovers who already had a library of 12-inch records, however, made it advisable to provide manual operation for 12-inch records. A kit of the necessary parts to make this change may be ordered from any Brunswick Distributor or Branch by specifying Part No. 1161. Directions for attaching these parts are as follows:

DIRECTIONS FOR INSTALLING PART NO. 4464 KIT ON MODEL 42 AUTOMATIC PANATROPE WITH RADIO TO PERMIT MANUAL OPERATION OF TWELVE INCH RECORDS

METHOD OF PROCEDURE

Parts Required:

- 1 Twelve-inch Record Kit (Part No. 1161) consisting of:
 - 1 Record guide plate assembly (right).
 - 1 Record guide plate assembly (left).
 - 2 Record guide screw-plates with screws.
 - 1 Switch cam and record creator assembly.
- Tools Required:**
 - 1 Back-saw with paper blades for cutting 3-16 inch steel stock
 - 1 Hand drill and the following drills, sizes:
 - 1--11-1617" drill (a 3-16" drill may be used instead if available)
 - 1--3-32" drill.
 - 1--12-inch flat file
 - 1--8-inch Bastard file.
 - The usual assortment of screwdrivers, pliers, soldering iron, etc., available in every service department.

All of the above tools should be at hand before the installation of this kit is attempted.

1. Removal of Record-Change Mechanism from cabinet:

- (a) Slide "oil drip" board out of the back of the cabinet.
- (b) Disconnect the power cable plugs between radio chassis and record-change mechanism.
- (c) Remove the four large nuts and associated rubber cushions located at the four corners of the cast iron base of the record-change mechanism.
- (d) Remove volume control knob on front control panel (fastened to shaft with one set screw).
- (e) Remove the wood panel containing the needle cups located around record hopper (held in place with three wood and three machine screws).
- (f) Remove four screws that fasten lid to lid supports and lay lid gently out of the way.
- (g) Lift record-change mechanism from cabinet by pulling entire assembly straight up.

Service Operations on X-1102 and X-1103 Chassis.**A. Adjustment of R. F. Compensating Condenser.**

If it is definitely known that no other defect exists in the set, antenna or ground, and if the receiver is insensitive, distorts or oscillates over any or all portions of the dial then the R. F. compensating condenser should be adjusted as follows:

- (a) Tune in a long wavelength station to maximum volume, or use special test oscillator at 600 K. C.
- (b) Place non-metallic screw driver in slot of compensating condenser (located beneath panel on right side, see Print CA-6039) and turn screw in a clockwise direction until the receiver goes into oscillation. Then turn screw in opposite direction until set goes out of oscillation, and will not whistle, squeal or howl on local stations. This is the correct position of the compensating condenser.

B. Adjustment of Oscillator Trimming Condenser.

If after above adjustment explained in paragraph "A" the set is still insensitive and distorts the signal, proceed to adjust the oscillator trimming condensers in the following manner:

Material needed: Special radio frequency oscillator equipped with milliammeter, non-metallic screw driver and necessary leads.

- (a) Place special oscillator near receiver and secure the transfer of R.F. energy by twisting output lead from oscillator around blue antenna lead of receiver. The receiver ground connection should be connected to ground. In order that the milliammeter on oscillator panel will function as a tube voltmeter it is necessary to place this meter in series with the plate lead of the second detector tube. This is accomplished by removing the red wire from the terminal strip of the Socket Power Unit and connecting the resonance meter in series with this lead and the terminal from which it was removed. So that the current drawn by the power tube shall not flow through the resonance meter remove the red wire from the terminal strip of the Rectox unit and connect a jumper wire from the terminal left vacant to the terminal on the SPU which is now connected to the resonance meter. Turn volume control to minimum on receiver. Turn receiver on, then turn oscillator on and watch needle on resonance meter. If needle goes off scale to the left, reverse meter connections. Adjust oscillator for 1400 kilocycle operation and tune receiver to secure maximum deflection on resonance meter, turning the volume control up just far enough during tuning operation to keep needle at about three-fourths full scale deflection.
- (b) Adjust trimming condenser under 2nd detector tube (condenser No. 1 in Print CA-6039) with insulated screw driver, until maximum deflection is obtained on milliammeter.
- (c) Tune oscillator to 600 kilocycles and adjust trimming condenser No. 2 (to be found under oscillator tube) to maximum deflection on milliammeter.
- (d) Now re-adjust at 1400 kilocycles as in paragraph "B."

Oscillator circuit is now adjusted to give 180 kilocycles beat note over entire tuning range.

C. Part 1—Adjustment and Neutralization of I. F. Transformer.

This operation is only to be attempted when Technician is sure that the lack of sensitivity or oscillation is not due to some other fault or when it is definitely known that one of the transformers is burnt out, shorted or grounded. To test the I. F. transformers, use ohmmeter, resistance bridge or voltmeter, with milliammeter, and Ohms' law, i.e., resistance is equal to the voltage divided by the current in amperes. Primary resistance should be 20 ohms, secondary 100 ohms overall or 50 ohms from grid to center tap

VOLTAGE TABLE

Never check voltages until all tubes are fully warmed up to proper operating condition. The voltage table given below is taken at 115 volts line with a Model 547 Weston set checker. It must be remembered that the voltage readings taken vary directly as the line voltage and also with the accuracy of the meters used. A variation of 10% plus or minus is permissible.

<u>TUBE VOLTAGES</u>		115 V. Line Volume Control Full On				
Type of Tube	Position of Tube	Filament Volts	B Volts	C Volts	NORMAL PLATE M.A.	Screen Volts
227	Oscillator	2.4	48.5		4.75	
235	Radio Frequency	2.4	240	2.15	2.75	27
224	1st Detector	2.4	230	4.35	.5	65
235	Intermediate	2.4	237	2.15	2.75	72
224	2nd Detector	2.4	100*	2.1*	2.5	35*
247	Pentode	2.4	250	16.5**	32.5	250
280	Rectifier	4.95			27 ea. plate	

*These readings are only comparative and are not true voltages applied. The volt meter, when the readings are taken at these points, is in series with a very high resistance.

** To read the 247 bias, read between H.K. speaker socket and ground.

INTERMEDIATE TRANSFORMERS:

The intermediate transformers are of the band pass type and of exceptionally high uniform gain. They are tuned to 175 kilocycles. The intermediate frequency trimmers are mounted on an isolantite base, preventing the transformer from becoming detuned due to the trimmer condensers absorbing moisture or warping. For this reason it should rarely, if ever, be necessary to re-track the intermediate frequency trimmers. In the event that it should be advisable to re-align the intermediate frequency coils, it is absolutely essential that a 175 kilocycle oscillator and an output measuring device be used.

ALIGNMENT OF RECEIVER:

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need re-tracking. Only when an intermediate coil has become defective due either to an open or burned out winding, should it be necessary to re-adjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the top of the intermediate shield can. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then re-check the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away, the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1295, 880, 650 and 550 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are especially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

**RECORD CHANGER
Model 10-12-C**

ASSEMBLY OF MOTOR TO BASE PLATE

The motor is attached to the base plate by three bolts, and mounted on rubber cushions. The brace that is over the turntable spindle and bolted to the base plate serves as an excellent gauge for aligning the motor in the center.

When removing the two screws that hold the turntable locating plate over the turntable spindle, preparatory to operating the instrument, be sure that the locating plate lines up with the holes that the screws are just removed from.

If the motor has become shifted in transit there will be a tendency for the holes in the locating plate and base plate to not perfectly line up.

In this case it is necessary to slightly loosen the three bolts holding the motor to the base plate and shift the motor to such position that the holes in the brace and the base plate align perfectly, and while the brace is still in place, tighten the suspension bolts to hold the motor in that particular position. The brace must then be removed before the turntable is mounted on the shaft.

In placing the turntable on the shaft, be certain that the rubber driving washer is in proper place with clips over the spindle pin.

After the turntable is put on the shaft, force it down by hand to be sure that the rubber washer and turntable are making perfect contact.

To level the turntable, place a straight edge across the turntable and adjust the three suspension bolts holding the motor to the base plate until the same distance is obtained from the bottom edge of the straight edge to the base plate near the three points where the suspension bolts are located.

This measurement should be approximately 11/16". This adjustment must be made so that there is no free movement of the motor by either of the suspension bolts being too loose.

TO NEEDLE ARM ADJUSTMENT FOR TEN INCH AND TWELVE INCH RECORDS

Pickup change lever No. 5569 is for changing the instrument from 10 inch to 12 inch record operation and vice versa.

The lever changes the position of the pickup return lever in such a manner that the needle is let down for the 10 inch or the 12 inch record, as desired.

To adjust for playing 10 inch records, loosen the forward lever stop No. 5525 and hold the lever in such a position that the needle will come down on a 10 inch record exactly 4-11/16" from the edge of the center pin. (A scale should be placed on the record with the end of the scale against the centering pin in such a position that the needle point will come down on the scale at the 4-11/16" inch position.)

When the proper location of lever No. 5569 is ascertained, then the front stop may be set snug against this lever and the screw tightened, which will allow the lever to always be thrown over to that exact position when desiring to play 10 inch records.

To adjust for playing 12 inch records, loosen the back lever stop No. 5527 and hold the lever in such a position that the needle will come down exactly 5-11/16" from the edge of the centering pin. (A scale should be placed on the record with the end of the scale against the centering pin in such a position that the needle point will come down on the scale at the 5-11/16" position.)

In the event you are unable to properly adjust for either 10 inch or 12 inch records by the above method, the adjustment as nearly correct as possible then refer to instructions on Page 6 and check Tone Arm Bracket Lever adjustment making certain the adjustment is correct.

Then loosen the lock nut holding the adjustment screw on the tone arm return lever No. CA5687 and turn the adjusting screw either in or out, as the occasion requires, to bring the needle to the proper location for the size record you are unable to adjust for by the lever stop method. It will then be necessary to readjust the lever stop which was originally set in position for the other size record.

The lever stop screws must be set tight so the lever stops will not be jarred out of position as the lever is thrown from one position to the other.

ADJUSTMENT OF PICKUP WEIGHT

Make this adjustment while music is being played, and only one record is on the turntable. With a delicate pair of scales, having a range of 0 to 12 ounces, catch the needle screw and lift the pickup from the record until the audio quality breaks, at which time a reading of 5/4 to 6 ounces should be shown on the scales. Raising or lowering the spring support No. 5575 which is affixed to the tone arm lifting rod No. 5553 adjusts the weight of the pickup.

GOVERNOR ADJUSTMENT

If the turntable speed cannot be regulated to 78 R. P. M. by the speed control lever located under the turntable, then loosen the set screw holding the governor to the governor shaft, and move the governor either in or out, as the case may be, to increase or decrease the speed of the motor. This adjustment must be made when the speed control lever under the turntable is in the center position.

To increase the speed of the turntable motor, move the governor out, and to decrease the speed of the turntable, move the governor in.

Do not, under any conditions, change the adjustment of the end thrust bearing screws. An occasional drop of oil on the governor brake will assist in maintaining a constant speed.

Service Notes**

CAPEHART CORPORATION

ASSEMBLY AND ADJUSTMENT OF OSCILLATING AND SPIRAL TRIP LEVER AND PICKUP SILENCER

To time the automatic switch so the instrument will automatically trip and change records, proceed as follows:

- First: Thoroughly acquaint yourself with the different part numbers.
- Second: Study the photographs carefully and note the relative location of the various parts.
- Third: Complete each of the following operations before going on to the next operation.

Operation No. 1.

Turn the master cam No. 5604 until the large timing mark is exactly above the timing mark on the tone arm lifting lever No. 5761.

Operation No. 2.

Hold the switch lever and cam assembly No. 5612 against the driven clutch No. 5616, so the radius of the cam will center against the clutch. (Be sure that cam No. 5612 is directly under the driven clutch No. 5616.)

Operation No. 3.

Set the pickup silencer switch No. 5643 against the casting bearing so the shaft of cam No. 5612 cannot be moved further toward the automatic switch.

Operation No. 4.

Hold the tail of cam No. 5612 against the lug on the inside of the master cam No. 5604 and adjust the trip lever No. 5611 until it is 1/16" beyond the catch in the oscillating trip lever No. 5667. This adjustment is made while the tail of the cam No. 5612 is held against the outside of the lug inside the master cam No. 5604.)

Operation No. 5.

Care must be exercised to have the end play of the oscillating trip shaft just free. This is taken care of in adjusting the pickup silencer switch No. 5643, so a good contact is made on the pickup short circuiting switch WHEN THE NEEDLE IS ON THE RECORD AND THE AUTOMATIC SWITCH HAS BEEN TRIPPED.

After the pickup silencer switch No. 5643 has been set according to the above instructions, the resetting of the automatic trip should allow the contacts on the pickup silencing switch to open. If the above operations are followed out in detail, and adjustments properly made, the clutch will automatically disengage when the pin on the clutch No. 5616 has travelled approximately one-half of the distance of cam No. 5612.

At the time the pin has travelled one-half of the distance of the clutch release cam, the small timing mark on cam No. 5604 should be exactly above the timing mark on the tone arm lifting lever No. 5761.

MODEL 10,12-G Service Notes

CAPEHART CORPORATION

ASSEMBLY AND ADJUSTMENT OF RECORD MAGAZINE

The record magazine pin No. 5565 must be tightened in the elongated hole in the magazine top plate No. A6736 in such a manner that the offset at the bottom of the pin extends directly away from the record support shelf.

The magazine pin must also be adjusted to such a position that exactly $4\frac{1}{8}$ " clearance is obtained between the back center of the offset at the bottom of the magazine pin, and the extreme right and left corners of the record support shelf. This adjustment is to be made when the record magazine is in 10 inch playing position.

TO ADJUST THE RECORD SUPPORT HOOKS

First, throw lever No. 5509 to the 10 inch position, and place a 10 inch record on the magazine pin, bringing the magazine down to playing position.

The record support hooks are adjusted by bending to proper position.

The record support hooks must be kept $1\frac{1}{16}$ " from the edge of the record support shelf and must be adjusted far enough back to just clear the edge of a 10 inch record, as the record is released from the record support shelf.

The record support hooks must also be low enough to clear the bottom side of the record, as it is supported on the magazine shelf.

The record support hooks should operate freely in either 10 inch or 12 inch position.

ASSEMBLY OF RECORD MAGAZINE AND STANDARD TO BASE PLATE: AND ALIGNMENT OF TURNABLE SHAFT

Mount the magazine and standard on the base plate with four bolts, tightening the bolts only tight enough to hold the complete magazine assembly in position. The magazine assembly must be so adjusted by shifting the standard on the base plate to bring the offset at the bottom end of the magazine pin exactly over the center of the point of the turnable spindle.

This adjustment cannot be made until the motor has been aligned according to the instructions on page one.

Enough clearance is allowed in the four bolt holes to take care of this adjustment.

After the adjustment is made perfect, the bolts must be securely tightened with lock washers.

ASSEMBLY AND ADJUSTMENT OF RECORD SLIDE SHELF AND FINGER

First, set the master cam No. 5504 so the lug on the cam at the side of the large timing mark comes directly under the end of the record release finger No. CA 5709.

The eccentric stud No. 5563 affixed to the main record release finger controls the adjustment of record release finger. Turn the eccentric stud No. 5568 until the record slide shelf No. 5521 is $1\frac{1}{64}$ " past the front edge of record support shelf No. 5520 at which time it should be possible to obtain a slight amount of clearance between the end of the record release finger and the point of the lug on the master cam without causing the safety spring, (which is a part of this lever assembly) to give.

The two points on the record slide shelf must come to the edge of the radius on the record support shelf at the same time.

RECORD WEIGHT ADJUSTMENT

The record weight No. 5759 must be so adjusted at the bearing pivot that the lower edge of the record weight does not touch the record slide shelf while in the 10 inch position, but comes low enough to hold one record in proper position for the slide plate to unload it on the turntable.

ASSEMBLY OF DRIVE BRACKET ASSEMBLY TO BASE PLATE AND MOTOR

The drive bracket No. 5551 must be bolted to the base plate in such a manner as to align the drive shaft with motor shaft so the coupling is free. A flexible coupling No. 5613 takes care of any minor lack of alignment between the drive shaft and the motor shaft, because of the motor hanging on rubber cushions.

ADJUSTMENT OF THE SPIRAL TRIP CAM

To adjust the spiral trip cam, turn the master cam No. 5504 until the small timing mark is exactly above the timing mark on the tone arm lift lever No. 5761 at which time the automatic trip can be manually reset or tripped at will.

Lay a steel scale, graduated in 64ths, flat on the record under the pickup, with the end of the scale against the turntable spindle in such position that the needle rests on the scale. By sliding the needle toward the center of the record, the spiral cam should cause the automatic trip to operate when the point of the needle is $1-49\frac{64}$ " from the edge of the turntable spindle.

If the automatic trip operates before the needle has come to $1-49\frac{64}$ " position, then the spiral cam is set too far ahead and must be moved very slightly back, while, if the needle comes closer to the turntable spindle than $1-49\frac{64}$ ", then the spiral cam is set too far back and must be set ahead to the proper position.

Failure to properly adjust the spiral trip cam so the automatic trip operates when the needle is $1-49\frac{64}$ " from the edge of the turntable spindle will cause the instrument to change records before the music is finished, or to not change records automatically.

To adjust the spiral trip cam No. 5529, slightly loosen the two screws holding the cam to automatic switch lever No. 5637 and pry the cam forward or back as required to obtain the proper setting.

To test the position of the spiral cam, it is necessary to carry the pickup back to the edge of the record each time to manually reset the automatic trip.

ASSEMBLY OF TRIP BRACKET TO BASE PLATE

The automatic trip bracket No. CA 5742 is mounted to the base plate by two nickel plated bolts and lock washers.

The end that the bakelite panel is mounted on is to be mounted toward the front of the base plate in such a manner that the bearing aligns perfectly with the bearing in the drive bracket. The final alignment can be made when the trip lever shaft No. 5612 is being installed and adjusted.

TO NE ARM BRACKET LEVER ADJUSTMENT

Set lever No. 5509 to 10 inch record operating position, and slightly loosen the clamp screw holding the bracket lever No. 5704 to the bracket under the tone arm base, and turn the bracket lever to such position that the slot, where the bracket lever clamps together around the bracket, is exactly centered on each side of the aligning notch cut in the lower rim of the bracket.

Then lay a scale, graduated in 64ths, on the turntable, placing the end of the scale against the turntable spindle in such position that when the needle is automatically let down the point of the needle will come to exactly $4-11\frac{16}$ " from the edge of the turntable shaft.

If the needle does not automatically come down at the $4-11\frac{16}$ " position refer to page 2 and make final adjustment at lever stop on lever No. 5509.

Care should be exercised to lock the tone arm return bracket lever, allowing .015 inch clearance between the cork insert and the tone arm base.

After the adjustment is properly made, tighten the clamp holding the tone arm bracket lever No. 5704 in place, which should leave ample clearance between the cork insert and the tone arm housing to allow perfect freedom of the tone arm operation.

If needle fails to feed into music groove, lift tone arm bracket lever No. 5704 tightly against tone arm housing and manually move tone arm back and forth to relieve any unevenness that might occur on the face of the cork insert.

OVER

MODEL 10,12-C
Service Notes

CAPEHART CORPORATION

TO NE ARM LIFT LEVER AND ITS ADJUSTMENT

Turn the master cam to such position that the small timing mark is directly above the timing mark on the tone arm lifting lever No. 5761.
Without a record on the turntable, and the needle in playing position, adjust the tone arm lift lever screw No. 62 until a visiting card can slide between the top of the lever screw No. 62 and the lower end of the tone arm lifting rod No. 5553.

TIMING OF CAM NO. 5576

To time cam No. 5576, turn the master cam No. 5504 by hand, bringing the lug near the large timing mark on the cam, directly under the end of the record release finger No. CA5709. At this time, hold the master cam in position and turn cam No. 5576 to the right until the corner of the cam touches but does not raise the switch contact lever on switch No. A5732.

Care must be exercised that the switch contacts on switch No. A5732 make perfect contact when cam No. 5576 is away from the switch lever, and when the cam is in the down position 1/32" clearance is maintained between the switch finger and the low side of the cam. This should insure a perfect contact at the switch points.

It is important, in the adjustment of cam No. 5576, that 1/64" clearance be allowed between the back side of this cam and the bearing through which the shaft passes.

After the above adjustment is made, check the instrument with one record on turntable, by shutting current switch off and see that instrument comes to an automatic stop position when the lug on the master cam No. 5504 has completely passed under the end of record release finger No. CA 5709. If the lug has not entirely passed under the end of the record release finger, then move cam No. 5576 to the left as little as possible to allow the lug to clear the cam when instrument stops automatically with one (1) record on turntable.

TO NE ARM RETURN LEVER AND ITS ADJUSTMENT

The tone arm return lever No. CA5687 is mounted on an eccentric pin with the bushing extended downward, the tone arm change and adjusting lever No. 5509 is mounted on the same shaft and located on the top back left corner of the chassis.

The sharp point of the cam, which is a part of the eccentric pin is to be mounted toward the tension spring which is affixed to the base plate, so that when the lever is thrown to 10 inch or 12 inch position the spring will hold the cam in that particular position.

The coil spring No. 5585 is attached from the lug on the tone arm return lever to the lug on the automatic trip bracket in such a manner that the spring is held as far down as possible by the lugs.

NOTE: The adjustment screw found on the tone arm return lever is covered in the instructions on page 1, and after once being properly set, should need no further adjustment.

Care must be exercised to have clearance between the high point of the master cam No. 5504 and the tone arm return lever.

MOUNTING AND ADJUSTMENT OF REJECTOR

The reject button is located at the right of the tone arm and is for the purpose of discontinuing a record before it has finished playing. With the automatic trip set and the instrument playing music, there should be 1/16" clearance between the bottom of the reject pin and the lateral pin affixed to the automatic trip lever No. 5657.

If this distance is too great, one will not be able to reject a record. If this distance is too small the automatic trip will not properly reset. Adjustment can be made by CAREFULLY bending the lateral pin to its proper position with relation to the rejector pin.

Fig. 5

- 5761 Tone Arm Lift Lever Assy.
- 5771 Tone Arm Insulating Bushing.
- 5774 Tone Arm Pivot Bushing.
- A5880 Tone Arm Bracket Assy.

ASSEMBLY OF TONE ARM HOUSING TO BASE PLATE

The tone arm base is attached to the base plate with three screws. This can be mounted only in the proper position.
The two pivot screws holding the tone arm to tone arm bracket must be so adjusted that the pickup is free to come down on to the record by its own weight and still the points of bearing must be in good contact in such a manner that the tone arm cannot be twisted from side to side.

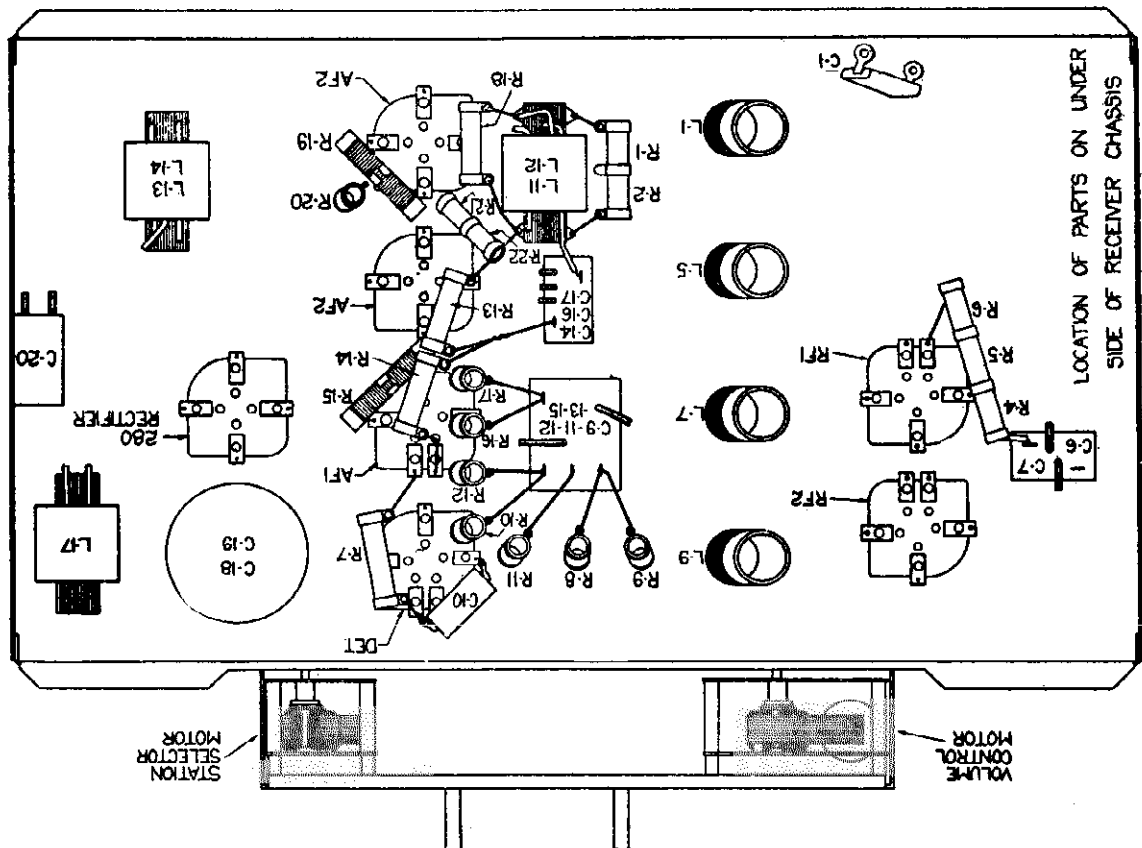

TO ADJUST FOR NEEDLE PLAYING POSITION

Turn the master cam until the small timing mark is exactly above the timing mark on the tone arm lifting lever No. 5761, at which time there will be no pickup weight on the tone arm lifting rod.

Then, without a record on the turntable, and the needle (of the length that is regularly going to be used with the instrument) properly inserted in the pickup, the "T" shaped tone arm rest No. 5584 should be adjusted to allow the tone arm to lower to such a position that the needle just clears the highest point of the turntable surface. **THIS ADJUSTMENT PROPERLY MADE WILL ELIMINATE THE POSSIBILITY OF THE NEEDLE DAMAGING THE TURNTABLE SURFACE.**

COLONIAL RADIO CORP.

MODEL 33,34,35 AC
Remote Control Notes

COLONIAL RADIO CORP.

The Remote-Control Automatic-Tuning Unit

Since the servicing of the remote-control automatic-tuning unit will be simple if its operation is thoroughly understood, the circuit diagram and the following explanation should be studied carefully.

* Fig. 4 shows the circuit used. As is seen, it consists essentially of two motors, one for turning the volume control and the other the tuning condensers, and means for controlling the direction and amount of rotation of the motors from a remote point. Each of the motors has two field windings, poled in such way that switching from one to the other reverses the direction of motor rotation.

When the remote-control push buttons are not pressed, the circuit is open and no current flows through the motors. When the "Vol. Inc." button is pressed, the circuit is completed through that field winding of the volume control motor which will cause rotation in the proper direction to secure an increase of volume. When the "Vol. Dec." button is pressed, the other field winding is connected, and the volume control is turned to a lower setting. Just before its minimum position, the volume control operates the receiver line switch. Since a friction drive is used no damage will result if the button is kept pressed. After the volume control has reached the limit of its movement, the motor will merely continue running with the friction drive slipping.

Study of fig. 4 reveals that when any one of the station buttons is pressed, the circuit is completed through the contact stud connected to it and the station-selector motor revolves, turning the tuning condensers and the split brass disk fastened to the condenser shaft. The motor continues to drive the condenser shaft (through a friction drive) until the insulating slit in the brass disk comes directly under the contact stud and breaks the circuit. When the slit is under the contact stud, the tuning condensers are in proper position for reception of the station. Should the momentum of the motor be sufficient to carry the disk past the point where the stud and slit coincide, the stud

will make contact with the other half of the disk, energizing the other field winding. This reverses the motor direction, bringing the disk back until the insulating slit and the contact stud do coincide.

The button marked "Quiet", when pressed, removes the voltage applied to the screen-grids of the R.F. tubes, preventing reception of stations while the automatic-tuning mechanism is in action.

Should either or both of the drive-motors refuse to run, or run in only one direction the following procedure may be followed: Connect one end of a length of wire to contact "C" of the receptacle (fig. 4.) and touch the other end alternately to each lug of the condensers mounted next to the volume control drive motor. If the motors run, and in both directions, the trouble is in either the cable, the remote-control push-button box, or the contacts on the brass disk. A continuity check will reveal the open circuit.

If the motors do not run when the wire is touched to the condenser lugs, the fault may lie in the voltage supply, the motor proper or in the 0.1 mfd filter condensers. An a.c. voltmeter connected from "C" (fig. 4) to the chassis should give a reading of approximately ten volts. If no reading is obtained, the trouble may be either a blown fuse or an open transformer. If a reading is obtained the 0.1 condensers should be tested for breakdown. If they prove perfect, the trouble is in the motors and they should be tested for shorted or open windings. In particular, the brushes should be examined for good contact with the commutator, and the commutator itself brightened with a piece of very fine sandpaper. In time the spider washers in the friction drive may lose some of their tension, resulting in slippage in the drive. These washers are easily removed and bent to increase their tension.

If the line voltage is above 110, the fuse should be in the right side of its mounting, facing the rear of the set. It should be put in the left side for a line voltage of less than 110.

Sometimes it is found that volume is better without a ground connection. This is due to the electric light wires acting as an antenna and feeding signals to the receiver. Under such conditions reception will usually be noisy. Connection of the ground wire causes the line filter condensers to effectively drain off both unwanted noise and whatever signal there may be picked up by the line.

The spark obtained when the ground wire is touched to the ground binding post or to the chassis is a normal occurrence. It is due to the discharge of the condensers used in the line filter.

A poor detector tube will create an objectionable hum in the speaker.

The fuse in the double mounting on the rear of the chassis provides a means for compensating for deviation of the line voltage from normal values. Normally the fuse is in the left side of the mounting, facing the rear of the chassis. It should be put in the right side only when the line voltage is known to be consistently below 110 volts. It is important that this adjustment be made, since excessive voltage will shorten the life of the tubes, and insufficient voltage will make the set insensitive.

The two models, 33AC and 34AC, are identical electrically except that Model 34 has a more sensitive loudspeaker, capable of finer reproduction. Further, the push-pull output transformer is mounted on the speaker frame instead of in the receiver chassis, as in the model 35.

The Colonial 33AC and 34AC are obtainable both with and without the remote-control automatic-tuning unit. This unit is easily installed in those receivers not having it as an integral part. It in no way interferes with the ordinary manual operation of the receiver, should that be desired. Either method of control may be used without the necessity for disconnecting, switching or changing anything. The employment of one-control system does not render the other inoperative.

Due to an automatic anti-overloading feature incorporated in the receiver, it will be found that when receiving strong signals, advancing the volume control beyond a certain point will result in a decrease in volume.

ACTUAL VOLTAGES APPLIED TO TUBES

	RF1	RF2	Det.	AF1	AF2	280 Rectifier
Plate Voltage	180v.	180v.	150v.	100v.	240v.
Control-Grid Voltage	-3	-3	-2	-6	-45
Screen-Grid Voltage	90	90	35
Plate Current	3m.a.	3m.a.	0.2m.a.	3m.a.	28m.a.

VOLTAGES AS READ ON A 1000 OHMS PER VOLT METER
(PLATE VOLTAGES ON THE 250v. scale; GRID VOLTAGES ON THE 50 v. scale)

Plate Voltage	180v.	180v.	60v.	70v.	235v.
Control-Grid Voltage	80	80	12	-0.5	-22
Screen-Grid Voltage	3m.a.	3m.a.	0.2m.a.	3m.a.
Plate Current	3m.a.	3m.a.	0.2m.a.	3m.a.	50 m.a. plate each plate

The discrepancies between the applied and the measured voltages result from variations in tubes and from increased voltage drops in series resistors due to the current taken by the voltmeter. Unless the measured voltages differ by more than 25 per cent from those given in the chart, it should not be taken as a definite indication of a fault. Usually any deviation greater than 25 per cent means trouble. These readings assume a 120v. line. If the line voltage differs from 120 volts, the measured voltages will differ from those given in the chart in approximately the same ratio.

Control grid voltage measured from cathode to ground or from cathode to filament. 245 grid voltage measured from grid to ground.

MODEL 37-P
Schematic

COLONIAL RADIO CORP.

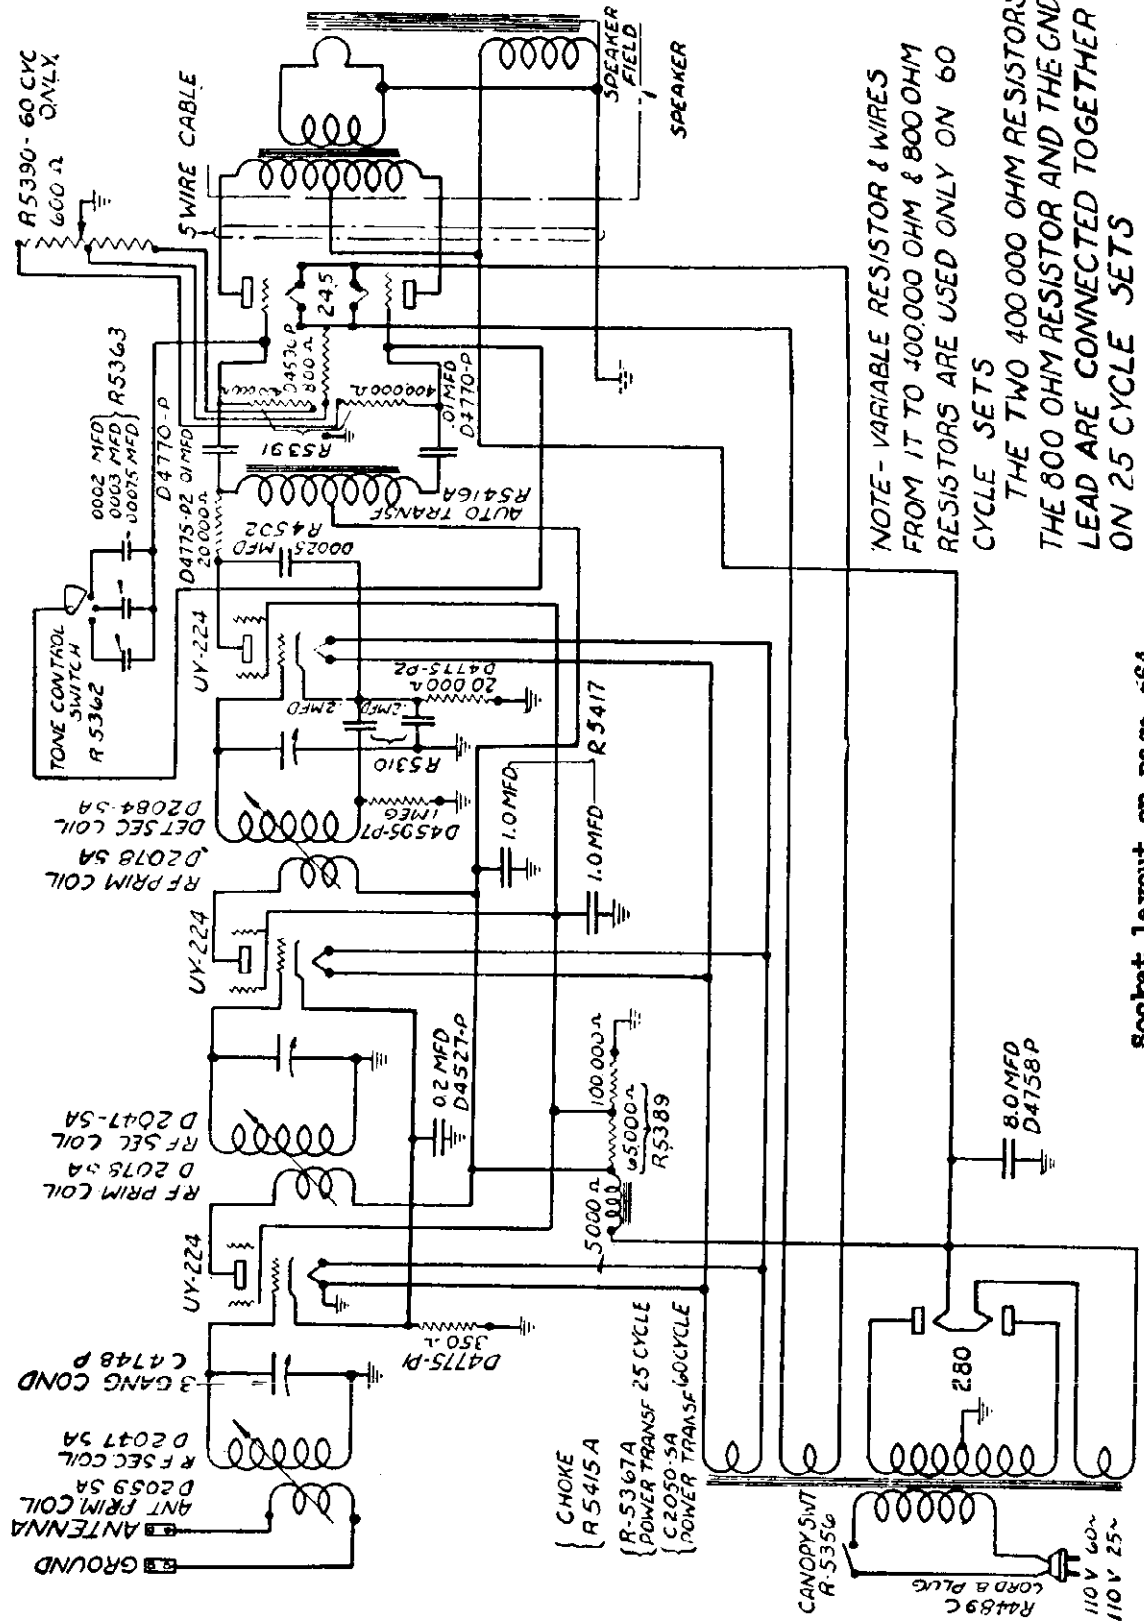

MODEL 37-P (PHONOGRAPH)

The phonograph switch operates with the line switch. The first quarter turn to the right turns set on and the next quarter turn throws in the phonograph. If the pickup is disconnected and the set is thrown to phono position, the set will not play and a loud hum will be heard in the loudspeaker. When playing records be sure to turn Radio Volume Control to the minimum position.

*The electrical characteristics of this receiver are identical to model 37.

MODELS 47-48 SUPERHET.

NOTE-In this set the hum across the field coil is used to buck out hum set up in the tube circuits. Causes of hum can be traced to defective detector or output tubes. (interchange output tubes) Shorted condenser or open resistors in hum filter circuit. The hum filter circuits consists of a 2000 ohm resistor and a 0.5 condenser in the grid bias resistor circuit. This connects from the cathode of the detector to the negative side of the speaker field. Other causes of hum are reversed speaker field, open or shorted condensers in detector circuit, open or grounded 20 ohm center tapped resistor, defective tone control, defective speaker or a defective electrolytic condenser.

Speaker Field Voltage		-	110									
Total Plate Current		-	80 ma.									

Note: All voltages measured with a 1000 ohm per volt meter, 250 volt scale, with volume level control at maximum. 247 output grid voltages were measured from filament to ground, and translator grid from cathode to ground. Grid voltages on the RF and IF will be variable when the set is operating. AVC plate voltages will be the grid voltages on RF IF and translator tubes.

Notes-Causes of no signals can be traced to some of the following reasons. Grid clips shorted to tops of tube shields. Open or shorted condensers. Unsoldered leads. Solder under tube socket terminals. Defective tubes. Oscillator not working. Open image suppressor coil. Defective speaker or shorted tone control connection. Poor quality can be traced to defective output or detector tubes. Set not tuned properly. A poor 235 in the IF, RF or translator sockets will give poor quality and unsatisfactory volume control. Shorted or open grid coupling condenser in the audio circuit, or open resistors in the audio circuits will also contribute to poor quality.

Oscillation can be traced to defective tubes, grid leads of detector and IF too close, or an open condenser in the plate circuit of the translator.

CROSLLEY RADIO CORP.

MODEL 7
MODEL 7-1
Converters

Circuit Diagram Model 7

This is a chassis for attaching to any broadcast receiver in order to adapt the latter to the reception of short-wave signals. It is of the superheterodyne type, the incoming signal being converted to a frequency within the regular broadcast range by the use of an oscillator and detector (see Service Bulletin No. A-1 for an explanation of the superheterodyne receiver).

After conversion to the appropriate frequency the signal is delivered to the aerial and ground terminals of the broadcast receiver.

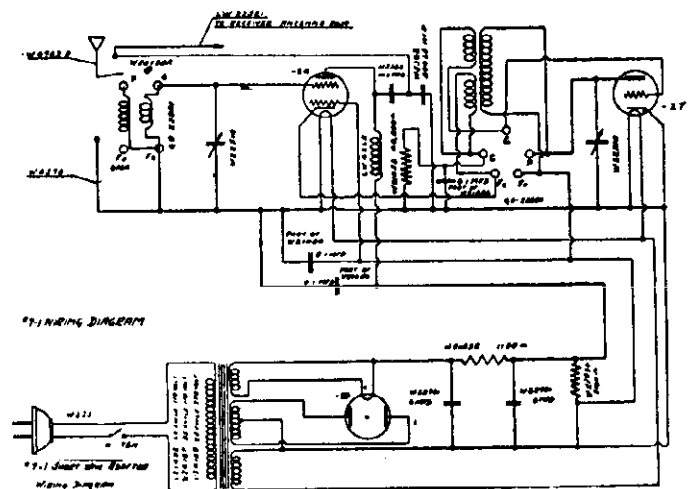

The chassis incorporates a -24 type, untuned buffer amplifier, a -27 tuned oscillator, a -24 tuned detector, and a -80 rectifier. Various frequency ranges are obtainable by the use of suitable coils, as explained in the instructions accompanying the chassis.

Model 7-1

Model 7-1 is a short-wave converter similar in general operation to Model 7, which has been described previously, but incorporating one less tube and having a tuned antenna circuit.

The tubes are as follows: a -24 first detector, a -27 oscillator, and a -80 rectifier.

Model 7-1

Circuit Diagram, Model 7-1

MODEL 7-2 Converter
MODEL 7-1 Voltage

CROSLLEY RADIO CORP.

Circuit Diagram, Model 7-2

Voltage Limits, Model 7-1

The following tube voltages are the approximate values which should be obtained with tubes in place and receiver connected to a 117½ volt line, using a voltmeter of 1000 ohms resistance per volt.

Filament Voltages	
Detector and oscillator tubes.....	2.3 to 2.7
Rectifier tube.....	4.5 to 5.5
Plate Voltages	
Detector tube.....	150 to 190
Oscillator tube.....	90 to 110
Grid Voltages	
Detector tube.....	3 to 5
Screen-Grid Voltage	
Detector tube.....	85 to 105

Model 7-2

This is a short wave adapter without a power pack which obtains its power from the broadcast receiver. Instead of plug-in frequency change coils, it is equipped with a coil changing switch, the desired frequency range being obtained by choosing the proper switch setting. There are five switch positions, four of which are for short-wave reception, and the fifth for operating the ordinary broadcast receiver.

Two tubes are used, a -27 oscillator and a -24 detector.

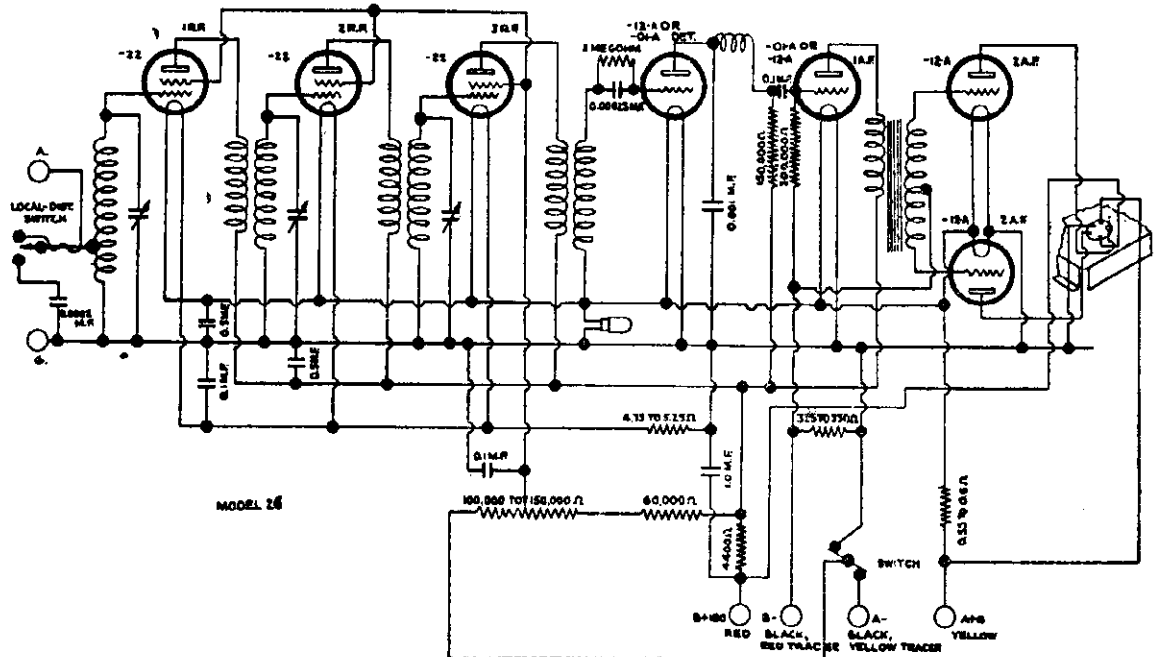

The adapter is for use only with receivers having pentode output tubes. On the end of the adapter power cable is a plug. One of the pentode output tubes is removed from the receiver, the adapter power cable plug is inserted in the pentode socket, and the pentode tube is inserted in the plug.

The tuning condensers are operated by a single dial.

The tube voltages depend to a certain extent upon the receiver with which the adapter is used. It is therefore not practicable to give them here.

CROSLLEY RADIO CORP.

MODEL 28, 27
Schematic, Voltage
Notes

-Circuit Diagram, Model 28.

Specifications

Models 27 and 28 are battery receivers identical in circuit and electrical design but differing in mechanical construction. They are six tube receivers, incorporating two -32 r. f. amplifiers, a -32 detector, a -31 intermediate audio amplifier, and -31 push-pull output tubes.

The batteries used are a 2 volt Eveready Air Cell or 2 volt storage battery, and four 45 volt "B" batteries.

Installation Notes

An aerial of moderate size will usually be satisfactory.

There is a battery resistor in the "A" battery cable. This should be removed if a storage battery is used instead of the 2 volt Air Cell.

The color code of the battery cable is as follows: Red lead (B+ 180 volts): to +45 terminal of fourth 45 volt "B" battery. Black lead with red tracer (B-): to minus terminal of first 45 volt "B" battery. Black lead with yellow tracer (A-): to minus terminal of Eveready Air Cell or 2 volt storage battery. Yellow lead (A+2 volts): to plus terminal of Air Cell or 2 volt storage battery.

When installing the receiver, check the tubes to see that they are inserted in their proper sockets, and make sure that the clip wires are connected to the clips of the screen grid tubes.

To be measured with speaker connected, volume control on full, and line voltage of 117½ (235 for 220 volt receivers). Measure plate and grid voltages with a high-resistance D. C. voltmeter (800 ohms or more per volt) from plate or grid tube contact to emitter contact. Use a low range A. C. meter for filament voltages.

Specifications

Model 59 is a compact, tuned radio-frequency receiver for operation from 110 volt and 220 volt A. C. house-lighting circuits. It is supplied in several cabinet styles in conjunction with Model 299 dynamic speaker.

The ends of the high-voltage secondary are connected to the plates of the rectifier tube, and the middle tap on it is connected to the negative side of the loudspeaker field ("B-"), and through one megohm and 300,000 ohm resistors to ground. The other side of the speaker field ("G") is connected to ground (chassis).

The positive plate supply circuit originates at the rectifier filament. One branch goes to the "B+" speaker terminal, whence it continues through the primary of the speaker output transformer to speaker terminal "P", and thence to the plate of the pentode tube.

A second branch of the B+ circuit goes through a 1100 ohm resistor to the screen grid of the pentode tube, and to the plates and screen grids of the other tubes. It is connected through a 300,000 ohm detector plate coupling resistor to the plate of the detector tube, through the primaries of the second and third radio-frequency transformers to the plates of the r. f. tubes, through a 100,000 ohm resistor to the screen grids of the r. f. tubes, a branch of the circuit returning to the r. f. cathodes through a 300,000 ohm resistor and through an additional resistor of 3 megohms to the screen grid of the detector tube.

The speaker field coil, in connection with two filter condensers—one (effective capacity 6 m. f.) of which is shunted across the speaker field and the other (effective capacity 12 m. f.) of which is connected from B+ to ground—acts as a filter circuit, eliminating hum.

Biasing of the r. f. tubes is accomplished by the volume control resistor. Adjustment of the volume control simultaneously varies the bias of the r. f. tubes and the value of a resistor shunted across the primary of the antenna coil. A 40,000 ohm biasing resistor is used in the detector emitter circuit. Biasing of the audio tube is accomplished by returning the audio grid to the negative side of the 300,000 ohm resistor in the B- circuit, connected to chassis.

Changes In Model 122

The following changes as compared with the circuit diagram shown herein will be found in some chassis.

1. The pentode grid resistor is 300,000 ohms instead of 1 megohm as shown on the diagram.
2. The volume control resistor is 650 ohms instead of 2500 ohms, as shown.
3. The 3,000 ohm resistor shown on the diagram just to the left and above the power transformer is changed to 1790 ohms.
4. The 1100 ohm resistor shunted across a portion of the volume control is deleted.
5. The 25,000 ohm resistor in the r. f. screen grid circuit is replaced by a 20,000 ohm resistor.

MODELS 122, 123, 124

Alignment of Tuning Condensers and Intermediate-Frequency Amplifier

The procedure

for aligning the tuning condensers is as follows:

1. Tune to a signal between 1300 and 1400 kilocycles.
2. Turn the volume control all of the way on. If all signals within the required range are too loud, connect a 0.00025 m. f. fixed condenser between the "A" and "G" terminals, and then couple the antenna very loosely to a wire connected to the "A" terminal.
3. If, when carefully tuned to the middle of the band, the dial reading does not correspond to the frequency of the signal, but is not more than two channels off, set the dial at the correct frequency, and adjust the padding condenser on the oscillator tuning condenser. (the tuning condenser nearest the front of the chassis) until the signal is loudest. Check the tuning by re-adjusting the station selector. It may not be possible to regulate the oscillator padding condenser so that the oscillator condenser is properly aligned with the exact dial setting, in which case align the padding condenser with a dial setting as close to the actual frequency as practicable.
4. After aligning the oscillator padding condenser, re-tune to a frequency between 1300 and 1400 kilocycles and carefully adjust the padding condensers on the other two tuning condensers until the signal is received with greatest volume.

Aligning Intermediate Frequency Stages

The primary and secondary circuits of the intermediate amplifier transformer must be tuned accurately to 175 kilocycles. They are aligned carefully at the factory, and no change should be necessary. In order to align them, an accurately tuned local oscillator operating at 175 kilocycles is essential. The procedure is as follows:

1. A local oscillator tuned accurately to 175 kilocycles frequency is required.
2. Remove the oscillator tube from the chassis. Remove the clip wire from the first detector tube. Connect the test oscillator output from the first detector grid to ground, and adjust the two screws at either side of the front I. F. coil for maximum reading on the output meter. Always re-align the tuning condenser after aligning the I. F. amplifier.

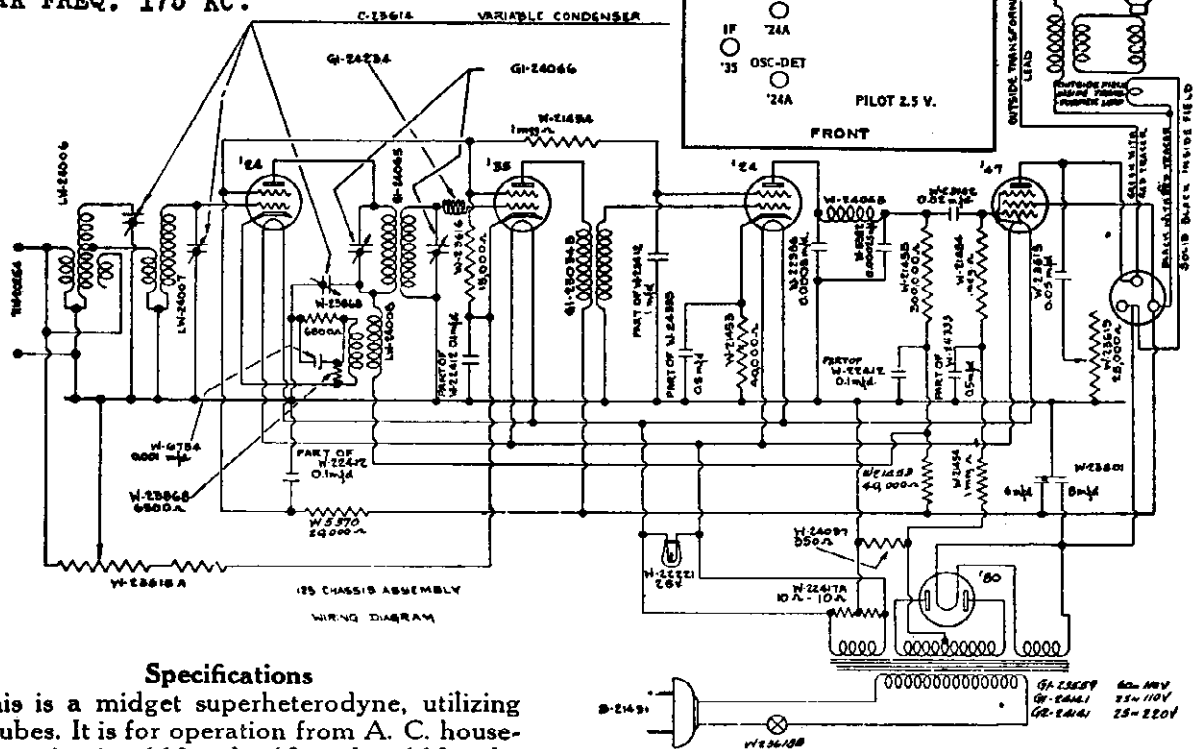

MODEL 125
Schematic
Voltage

CROSLY RADIO CORP.

MODEL 125 SUPERHETERODYNE

Model 125

PEAK FREQ. 175 KC.

Circuit Diagram, Model 125.

Specifications

This is a midget superheterodyne, utilizing five tubes. It is for operation from A. C. house-lighting circuits, 110 volts 60 cycles, 110 volts 25 to 50 cycles, or 220 volts 25 to 60 cycles

Instead of being coupled directly to the antenna-ground system is coupled to the detector-oscillator through a double tuned selector circuit. This increases the selectivity of the circuit.

The first tube acts both as a detector and oscillator. The oscillator circuit is tuned by a variable condenser—one of the three comprising the station selector gang—as shown on the diagram. The other two station selector condensers tune the grid circuit of the detector-oscillator and the pre-selector circuit.

The detector-oscillator is coupled to the intermediate frequency amplifier stage by an I. F. transformer, both primary and secondary of which are tuned to 175 kilocycles by small adjustable condensers shunted across them. These circuits must be tuned accurately to 175 kilocycles for efficient operation. A radio-frequency choke is in the grid circuit of the I. F. tube.

The timing condenser adjustments are made from the top of the chassis through the three holes in the condenser shield; the I. F. transformer adjustments through the holes at the left side of the chassis, near the front, as viewed from the front of the receiver.

Voltage Limits

The following data shows the average voltages which will be obtained when measurements are made on Model 125 Chassis using a voltmeter of 1000 ohms resistance per volt. Some of these voltages do not represent actual voltages present at the tube elements. A typical example of this is the grid voltage of the pentode tube, which is actually about 16 volts, but only shows about 1 volt when measured in this way.

Screen Grid Voltages

- Pentode .200 to 230
- I. F. 75 to 95
- 1st Det. . 75 to 95
- 2nd Det. 15 to 25 (250V scale), 3-8 (50V scale)

Plate Voltages

- Pentode 200 to 230
- I. F. 200 to 230
- 1st Det. .160 to 180
- 2nd Det. 75 to 90 (250V scale), 20-30 (50V scale)

Control Grid Voltages

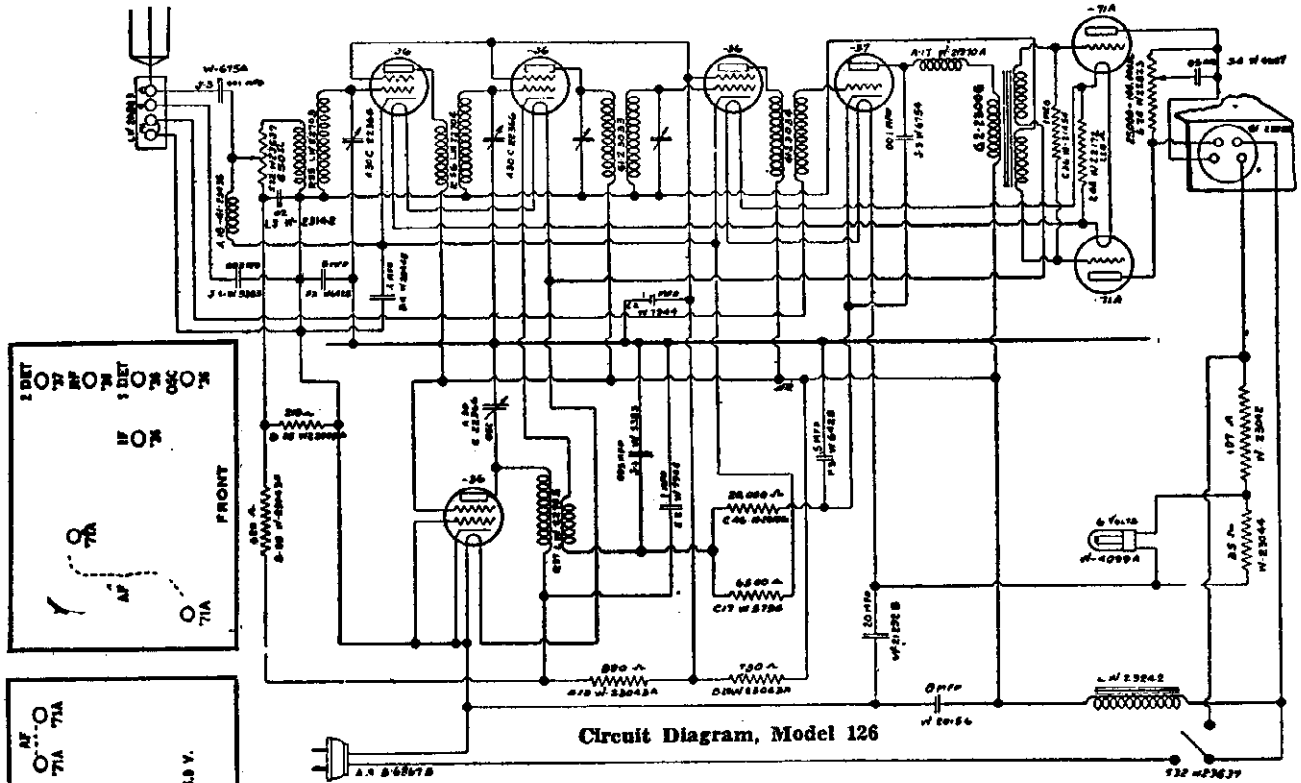

- Pentode .0.5 to 1.5
- I. F.1.5 to 2.5 (20-30 vol. cont. off)
- 1st Det. .5.5 to 7.5
- 2nd Det. .4.0 to 6.0

Filament Voltages

- All tubes but rectifier2.3 to 2.5
- Rectifier tube4.6 to 5.0

Voltage Limits

To be measured with tubes in place, speaker connected, and line voltage of 117½ (235 for 220 volt receivers).

Filament Voltages	
All tubes but rectifier	2.3 to 2.5
Rectifier tube	4.6 to 5.0
Plate Voltages	
All tubes but second detector and pentodes	170 to 200
Second detector	0
Pentode output tubes	270 to 300
Screen Grid Voltages	
All screen grid tubes but pentodes	75 to 95
Pentode output tubes	230 to 250
Control Grid Voltages	
R. F. and I. F. amplifiers	2.5 to 3.5
First detector	8 to 10
Oscillator	8 to 12
First A. F. amplifier	8 to 12
Pentode output tubes	14 to 18

Model 127

Hum Adjustment

With properly matched output tubes, the hum level of this chassis is very low. The audio transformer shield may be rotated, after loosening the three hold-down screws, and so adjusted that the hum is reduced to a minimum. This adjustment is made at the factory and should not have to be made in the field unless it is necessary in servicing the receiver to loosen or remove the audio transformer shield. If the receiver hums, try other tubes in the output before attempting to adjust the transformer shield.

MODEL 127

Parts Lists

Notes

CROSLLEY RADIO CORP.

60 cycle, or 220 volt 25 to 60 cycle circuits. The tubes used are as follows: a -35 or -51 radio-frequency amplifier, a-35 or -51 first detector (-24 tubes were used for the first detectors in the earlier chassis of this series, a -27 oscillator, a -35 or -51 first intermediate-frequency amplifier, a -24 second intermediate-frequency amplifier, a -27 diode second detector and automatic volume control tube, a -27 audio-frequency amplifier, two PZ or -47 pentode push-pull output tubes, and a -80 rectifier.

When installing the receiver, make sure that the tubes are in their proper sockets as shown on the connection diagram in the instructions, being particularly careful to see that the -24, and -35 or -51 tubes are not interchanged.

Three phonograph terminals, marked "P", "C", and "S", are provided for use with Crosley phonograph pick-ups. Before connecting a phonograph pick-up, cut the wire between terminals "P" and "C". If the phonograph pick-up is later disconnected, these terminals should be wired together again.

The second detector is of the diode type, and acts also as an automatic volume control tube.

The antenna coil and the interstage coil between the R. F. stage and the tuned selector circuit are connected so as to introduce a certain amount of capacity coupling as well as inductive coupling, as in previous Crosley Models.

Audio Coupling

The diode detector is resistance coupled to the first audio tube, the coupling resistor serving as a volume control. From the detector grid, the coupling circuit continues through a 0.02 m. f. coupling condenser to phonograph terminal "C", whence it continues through a strap between terminals "C" and "P", not shown in the diagram, and from terminal "P" to one end of the volume control resistor, the other end of this resistor being grounded. Since the emitter of the second detector is also grounded, this completes the detector circuit.

Type -24 Detector in Early Chassis
Earlier series of this chassis used a -24 type first detector tube. Connections were the same throughout, except in the tuned selector circuits between the R. F. and the first detector. The grid circuit of the first detector was connected directly to the chassis, instead of through the 300,000 ohm isolating resistor and 0.1 m.f. by-pass condenser shown on the diagram. The lower end of the interstage coil secondary, coupled to the R. F. plate circuit, was connected directly to the chassis, instead of to the grid circuit of the second detector as indicated here.

Alignment of Tuning Condensers and Intermediate Frequency Amplifier

To align the tuning condensers, the same procedure should be followed as outlined for Model 122, except that there are three, instead of two, condensers in addition to the oscillator condenser to be aligned.

Follow the procedure outlined in the same bulletin for aligning the intermediate amplifier transformers, adjusting all four aligning condensers, one at a time.

Hum Adjustment

With properly matched output tubes, the hum level of this chassis is very low. The audio transformer shield may be rotated, after loosening the three hold-down screws, and so adjusted that the hum is reduced to a minimum. This adjustment is made at the factory and should not have to be made in the field unless it is necessary in servicing the receiver to loosen or remove the audio transformer shield. If the receiver hums, try other tubes in the output before attempting to adjust the transformer shield.

Specifications

Model 127 is a compact, ten tube super-heterodyne chassis. It is for operation from A. C. house-lighting circuits, and may be obtained for 110 volt 25 to 50 cycle, 110 volt

In the later models the speaker field is in the negative lead and part of the drop across it is used to bias the grid of the power tube. A bucking coil is used in the speaker to keep the field ripple out of the voice coil.

The R. F. stage is impedance coupled and there is a small coupling condenser fastened on the lower end of the R. F. coil. If the set is weak or oscillates at the high frequency end of the band a slight adjustment of this condenser will remedy the trouble. After adjusting this condenser the gang condenser should be checked for alignment with the rotor plates nearly open.

The filter circuit consists of an 8 M. F. and 4 M. F. electrolytic condenser and the 2000 ohm speaker field. The speaker field is in the positive lead and the power tube is self biased by a resistor from the filament circuit to ground. This resistor is by-passed by an 8 M. F. condenser.

ECHOPHONE RADIO MFG. CO.

MODEL 60
Schematic

The filter circuit consists of two 8 MF electrolytic condensers and the 1500 ohm speaker field. The hum balance circuit is used in connection with the power tube bias resistors. The speaker field is in the negative lead and part of the voltage drop across it is used for biasing the power tube. A bucking coil is used in the speaker to keep the field ripple out of the voice coil.

The filter circuit consists of an 8 MF and a 4 MF electrolytic condenser and the 1200 ohm speaker field. The field is in the positive lead and the output tubes are self-biased by a resistor between the filament circuit and ground. A bucking coil is used in the speaker to keep the field ripple out of the voice coil.

VOLTAGE TESTS

All voltages given were tested on a 250 volt scale of 1000 ohms per volt meter.

All voltage tests were made with volume on full, and tone control in off position, no signal in receiver, line voltage 115 volts with A. C. line connected to tap of transformer as shipped from factory.

Model 60 Superheterodyne

First Det. Plate to ground 230 to 250 volts	247 Plate to ground 230 to 245 volts

The Echophone, Model 90, is an 8-tube Superheterodyne, employing variable MU and Pentode Tubes.

The circuit consists of a pre-selector; one stage of high gain R.F. amplification using a type 235 tube; a first detector using a type 235 tube; one stage of intermediate frequency amplification using a type 235 tube; a second detector using a type 235 tube; a single audio stage using two type 247 Pentode tubes in a resistance coupled push-pull circuit; an oscillator using a type 227 tube, and a power supply system using a type 280 tube.

The antenna and pre-selector coils are mounted on top of the chassis, and are tuned by the first and second sections of the gang condenser.

MODEL 90

Voltage

Notes

ECHOPHONE RADIO MFG. CO.

Model 90—Superheterodyne

The first detector is of the grid biased type. The second detector is a type 235 tube used as a space charge detector. In this system, the screen grid is used as a control grid and a small positive voltage is applied to the top grid which is normally used as the control grid. A grid leak and condenser are used in the control grid circuit, and the negative voltage developed across the grid leak when strong signals are received is fed back to the R.F., first detector and I.F. grids which gives the semi-automatic volume control, and prevents overloading of the second detector. A phonograph pickup jack is incorporated in the grid return of this tube.

The R.F. Circuit is a high gain impedance coupled type with capacity coupling condenser mounted on coil. This condenser should require no adjustment after leaving factory. The fourth section of variable condenser tunes the R.F. circuit.

The oscillator circuit is of the conventional tuned grid type with plate feed back, and is inductively coupled to the grid circuit of the R.F. stage.

The intermediate frequency amplifier has a total of four tuned circuits, and is adjusted to 175 K.C.

The volume control acts as a dual control by varying the bias on the R.F. and I.F. tubes, and by varying the antenna input to the antenna coil.

The filter circuit consists of an 8 MF and a 12 MF electrolytic condenser, and the 1200 ohm speaker field. The field is in the positive lead, and the power tubes are self-biased by a resistor from the filament circuit to ground. A bucking coil is used in the speaker to keep the field ripple out of the voice coil.

MODEL 10,11,30,31
MODEL 10Z,11Z,30Z,31Z
Notes

NEUTRALIZING AND COMPENSATING INSTRUCTIONS FOR
Fada 10, 11, 30, & 31 Receivers - 60 cycles
Fada 10Z,11Z,30Z,& 31Z Receivers - 25 cycles

NEUTRALIZATION: The first neutrodon is located to the right of the 1st RF tube; the second neutrodon is in front and slightly to the right of the 2nd RF tube; the third neutrodon is directly between the 3rd RF and detector tubes. The neutrodons are numbered according to their respective RF stages. The tube positions are indicated on the card attached to the cabinet lid or back, or back drop door in console model. The use of headphones is strongly recommended.

1. Tune in a strong low wave station or local oscillator of about 250 to 300 meters.
2. Remove the 3rd RF tube and insert a dead tube (a good tube with one heater prong cut off close to base)
3. Using the Fada special adjusting tool (part No. 1356-Ms) turn the third neutrodon to the left or right to point of MINIMUM signal. Replace the live tube.
4. Repeat operations 2 and 3 in the second and first RF stages.

COMPENSATION: Turn the tuning control towards the 100 degree mark until the edges of the rotor plates on tuning condensers two and three (numbered from left to right facing front of set) are exactly flush with the stator plates. Next, using the vernier knob set the rotor plates of the first condenser flush with the stator plates. **DO NOT MOVE THE VERNIER KNOB DURING REMAINING OPERATIONS.** The compensating condensers are mounted on the top of each tuning condenser. They are adjusted by using a socket wrench on the large nut. After the adjustment has been completed the large nut should be held with a flat open end wrench while the small lock nut is tightened with a socket wrench. These wrenches do not need to be insulated. The small lock nut should be removed before starting to compensate.

1. Using headphones if possible, tune in a weak low wave station of about 250 to 300 meters.
2. Adjust each compensating condenser by turning the large nut either to the left or right to point of MAXIMUM signal. As the signal increases during the compensation it should be reduced by the volume control so that small changes in the compensating condensers will be effective on the ear.

The order of compensating is immaterial. If the maximum points are not pronounced enough, decrease the dial setting by about one or two degrees and bring the signal back to maximum with the compensating condensers. Check the set for performance over entire range. Always recompensate whenever the setting of a neutrodon is changed.

FADA RADIO & ELECTRIC CORP.

MODEL 16,17,32
 MODEL 16-Z, 32-Z
 Notes

NEUTRALIZING AND COMPENSATING INSTRUCTIONS FOR
FADA 16, 17 & 32 RECEIVERS - 60 CYCLES
FADA 16-Z & 32-Z RECEIVERS - 25 CYCLES

NEUTRALIZATION: There are three neutrodon, one for each rf stage, each numbered to correspond with the stage neutralized, located as follows - 1st between 1st & 2nd rf tubes - front row, that is second and third tubes from electric unit; 2nd between 2nd and 3rd rf tubes, and 3rd between 3rd rf tube and detector.

To neutralize receiver, substitute head phones for loud speaker and proceed as follows: -

- 1st Carefully tune receiver to strong station or local oscillator at 250 to 300 meters.
- 2nd Remove 3rd rf tube and substitute a dead tube (prepared by cutting off one heater prong of a good tube close to base.)
- 3rd Using special Fada adjusting tool (Part No. 1356-Ms) adjust neutrodon to position of minimum signal. Replace live tube.
- 4th Repeat procedure on two remaining rf stages.

COMPENSATION: The compensating condensers are located on the top of their respective tuning condensers. They are adjusted by using a socket wrench on the large nut. After completing the adjustment, the large nut should be held with a flat open-end wrench while the small lock-nut is tightened with a socket wrench. Since the movable plate is at ground potential, it is not necessary to insulate wrenches. The first tuning condenser (nearest electric unit) holds the antenna compensator which is adjusted by means of its knurled nut.

To compensate receiver, substitute head phones for loud speaker and proceed as follows: -

- 1st Carefully tune receiver to weak station or local oscillator at 250 to 300 meters by adjusting tuning control knob.
- 2nd Beginning with antenna compensator carefully adjust each compensator for maximum volume. (It is always good practice to keep the volume control set at maximum when compensating.)
- 3rd After receiver has been compensated in accordance with above instructions, carefully retune and repeat the procedure.

MODELS 25, 35-B

FADA RADIO & ELECTRIC CORP. Sensitivity Adjustments

Sensitivity Adjustment Fada-25 Receiver

Present production FADA-25 receivers incorporate a sensitivity adjusting tool. Adjustment is made with a special neutralizing tool part number 1356MS. Facing the rear of the receiver there appears a row of three neutrons between the r.f. tube sockets. The one on the extreme right, however, is not connected to the usual neutralizing circuits, but is a sensitivity adjustment. Turning this neutron up (i.e., to the left) results in minimum circuit reaction and in a more stable receiver. Turning this neutron down (i.e., to the right) increases circuit reaction, and consequently sensitivity and selectivity. Advancing this neutron too far (i.e., down to the right) will cause long wave oscillation. Maximum sensitivity and selectivity occur when the receiver is adjusted almost to the point of oscillation.

Care should be exercised to insure that everything is in order before the sensitivity adjustment is moved. This adjustment must never be advanced to a point at which sustained oscillation occurs. This adjustment is a useful tool only when carefully used—never attempt to make up for poor compensation or defective tubes.

Sensitivity Adjustment On Fada 35B

A sensitivity adjustment is incorporated in the FADA 35B. The adjustment appears as a neutron (which must be adjusted) with special neutralizing tool part number 1356MS located between the detector tube and the fourth r.f. coil as shown in sketch. The receiver is adjusted at the factory for best operation on an average antenna. Under no circumstances should this adjustment be disturbed until:

The sensitivity adjustment effects long wave (i. e. 350 meters to 550 meters) sensitivity and selectivity. Turning the adjustment to the right (i. e. down) increases circuit reaction and consequently long wave sensitivity and selectivity. Turning the adjustment to the left (i. e. up) decreases circuit reaction and consequently long wave sensitivity and selectivity. To make sensitivity adjustment proceed as follows:

Make sure the receiver, tubes, antenna and ground are right. Carefully compensate for antenna in use following instructions of receiver instruction sheet. Carefully tune receiver to long wave station (above 500 meters). Turn volume control to maximum. Turn adjustment up or down as required a short distance (say one half turn at a time) and tune thru station noting swish as station is tuned in and out. Adjust to desired point being sure receiver does not squeal (i. e. oscillate).

The Fada 35-B has a hum adjustment located on the rear of the receiver chassis near the phonograph jacks. This adjustment appears as a small shaft with a slot adapted for a screw driver. This is sealed with ambroid after being adjusted at the factory, but the seal may be broken if installation conditions warrant. To adjust receiver for minimum hum, insert screw driver in slot and turn slightly to right and left to position of minimum hum. During this operation the volume control must be turned to zero and the power line plug must be inserted in the socket in the position of minimum hum

FADA RADIO & ELECTRIC CORP.

MODEL 40
NotesCOMPENSATING INSTRUCTIONS FOR
FADA 40 Receiver - 60 CYCLES ONLY

The compensating condensers are located on the top of their respective turning condensers. They are adjusted by using a socket wrench. Since the movable plates are at ground potential it is not necessary to insulate the wrench.

The first tuning condenser on the extreme right (facing rear of Receiver) holds the antenna compensator which is adjusted by its knurled nut.

The static shield which is mounted on four studs, should be removed by loosening the four thumb nuts. This shield has no effect whatsoever on Receiver adjustment, consequently it may be left off during compensation, etc.

INSTRUCTIONS FOR
SENSITIVITY ADJUSTMENT

The sensitivity adjuster appears as a neutrodon (which must be adjusted with special neutralizing tool, part No. 1356-Ms) located between the detector tube and the fourth R.F. coil as shown in instruction sheet which accompanies each Receiver. The Receiver is adjusted at the factory for best operation on an average antenna.

The sensitivity adjustment effects long wave (i.e. 350 meters to 500 meters) sensitivity and selectivity. Turning the adjustment to the right (i.e. down) increases circuit reaction and consequently long wave sensitivity and selectivity. Turning the adjustment to the left (i.e. up) decreases circuit reaction and consequently long wave sensitivity and selectivity. To make sensitivity adjustment proceed as follows:

Make sure the Receiver, tubes, antenna and ground are right. Carefully compensate for the antenna in use, following instructions given in Receiver instruction sheet. Carefully tune Receiver to a long wave station (as near 500 meters as possible). Turn volume control to maximum. Advance the sensitivity adjustment (i.e. tune down to right) a short distance (say one-half turn at a time) and tune through the station, noting the swish as the station is tuned in and out. Continue this procedure until the Receiver squeals (oscillates) and then retard neutrodon until Receiver is just below the point of oscillation (i.e. does not oscillate). This adjusts the Receiver for maximum radio frequency performance. If the Receiver oscillates at long waves before the adjustment of the neutrodon has been altered, the reverse procedure is followed. That is, the neutrodon is retarded (i.e. up to the left) a half turn at a time until the oscillation, noted when turning thru a station, ceases. Oscillation is evidenced by a pronounced squeal or note with changes in pitch as the tuning dial is moved. Do not confuse carrier swish or heterodynes between stations with oscillation.

(KA)

Voltage

Model 41,42,44,46,47 (KA)

VOLTAGE READINGS ON 60-CYCLE KA RECEIVER

The following voltage readings are to be taken at points beneath the chassis. Be sure that the overall condenser and tube shield housing cover is fastened in place or else oscillation will occur which will affect voltage readings. The speaker field coil must remain connected in the circuit and all tubes must be in their correct sockets, otherwise extensive damage will be done.

1. General Information

Volume Control set at any position but no signal
Voltage regulator tap in high position.

Line Volts	Line Watts	Filament Volts			Plate-Cathode Volts			Screen Volts RF
		Rect.	Pwr.	Amp.	Pwr.	RF	Detector Det.Amp.	
100	78	4.2	2.1	2.1				
110	96	4.8	2.35	2.35				
115	100	5.0	2.5	2.5	233	152	**	85
120	114	5.15	2.6	2.6				
130	132	5.5	2.8	2.8				

** A voltage reading cannot be obtained at the plate prong of the two (2) element detector. The plate voltage reading on the detector amplifier should also be ignored, because to take such a reading, it becomes necessary to shunt the voltmeter across several of the resistances in the circuit and the result is a reading of about 20 volts which will vary in accordance with the intensity of the signal received.

Voltages Across Condenser Block Sections (Line Voltage 115)

Radio Frequency Coils:

The R. F. Coils are of the high reactance type, accurately matched with the condensers.

There are two types of coil sets as well as two types of condenser gangs, and are designated by the markings as follows:

A. The coils used first with precise type condensers, are wound with 116 turns, space wound, and have no color designations on tubing.

B. No. 7829—7830. These coils used with precise condensers, are wound with 122 turns, space wound and have a red mark of paint on base of tubing.

C. No. 8010—8011. These coils used with General instrument condensers, have 126 turns, space wound, have a marking of white paint on base of tubing.

Positions:

Coils No. 8010—7829. The first R. F. coil is located at the front of chassis and is not interchangeable with the second and third R. F. coils.

Coils No. 8011—7830. The second and third R. F. coils are interchangeable and are located in their respective places.

The first R. F. coil differs from the others, as it does not have a choke bucking coil inside of the tubing as the others.

Coil cans are very essential to aid selectivity and reduce interference.

The Condenser Gang:

The tuning condensers are graded in three types.

The condensers can be defined as follows:

The first precise type, have no extended shields between the condensers.

No. 7832. The second precise type have two shields extending between the center and outside condensers.

No. 7872. The general instrument type have four shields and can be easily distinguished from the others.

VOLTAGES

Referring to the Circuit Diagram, the following voltages are given throughout the circuit using straight A. C. or D. C. meters.

CHECK FROM GROUND OF CHASSIS TO POINT DESIGNATED.

GROUND IS NEGATIVE. POINT DESIGNATED IS POSITIVE.

SET VOLUME CONTROL AT MINIMUM.

SET CHASSIS ON ONE END WITH BOTTOM IN VIEW.

Use 600 volt D. C. meter—1000 ohms per volt.

Rectifier filament or choke No. 7825 (beginning).....	440 volts
Choke No. 7825 (ending).....	390 volts
245 power tube plate or choke No. 7735.....	368 volts

Use 300 volt D. C. meter—1000 ohms per volt.

Detector plate or resistor No. 7785 (ending).....	48 volts
R. F. Plate or red wire of condenser No. 7015.....	242 volts
245 grid or resistor No. 7785 (ending).....	48 volts
Detector grid or green wire of condenser No. 7879.....	22 volts
Detector cathode or resistor No. 7786.....	12 volts
R. F. cathode or black wire condenser No. 7015.....	2 volts
R. F. Screen Grid at red wire volume control or at Resistor No. 7783 (end).....	120 volts

DETECTOR

It is quite a question in the Loftin-White direct coupled amplifier where detection actually takes place, but for the time being, we will call the type 224 tube the detector, and the type 245 tube the audio frequency amplifier. The detector can be considered of the high bias type. A 100,000 ohm resistor in the cathode circuit of the 224 tube connects the cathode approximately 15 volts positive with respect to ground. This is too high a bias for the 224 to operate as a detector. Therefore the grid return is brought back to a position on the network about 12 volts position with respect to ground. This leaves a three volt bias on the grid of the detector which is the proper value for detecting weak signals. When a strong signal is delivered to the grid of the detector, the detector plate current increases. This changes the cathode voltage from 15 volts approximately to 20. At the same time, the plate current in the network decreases making the grid return approximately 8 volts positive with respect to ground. The effective bias on the grid of the detector tube is therefore about 12 volts which is the proper value for detecting the strong signal. In measuring the bias on the detector, the readings will be affected a great deal by the type of voltmeter used. It is best for the service man to take these readings on a set which is known to be good with his own voltmeter. In the future these readings can be taken as standard and questionable sets compared to them.

AUDIO

The peculiar part of measurements on this audio system is the high voltage from the 245 tube plates to ground, the high voltage from the filament to ground and the impossibility to read the grid voltage with a meter. The best indication of the Loftin-White detector amplifier condition is the plate current of the type 245 tube. This should be approximately 38 milliamperes. This reading will vary quite a bit with different tubes and with the line voltage.

Tube	Filament V	Plate V	Cathode V	Grid V	Plate Current
1st R. F.	2.5	160	3	0	3.
2nd R. F.	2.5	160	3	0	3
Detector	2.5	varies	14	12	.25
Audio Rectifier	2.5	380	160	varies	40
					20 ma. per Plate

Line Voltage 120—
 All plate voltages are read from plate of the tube to ground.
 All cathode voltages are read from the cathode to ground.
 All grid voltages are read from the grid of the tube to ground.

A special dynamic speaker with a 4700 ohm field coil is used as part of the Loftin-White resistance network. The rectifier tube is used as a full wave rectifier and supplies the total plate current of the set which is approximately 38 milliamperes at 400 volts.

THE U1 SUPERHETERODYNE CIRCUIT

The U1 Chassis uses seven tubes as follows: one 5Y1 variable Mu tube for the first tuned R. F. stage, one 224 screen grid tube for first tuned detector, with a 227 oscillator tube signal beating into the first detector stage. One 5Y1 Variable Mu tube for the intermediate R. F. stage and a 224 for power detector. This second detector or Power Detector is resistance coupled to the power tube which is a 2Z Pentode type tube. One 280 tube is used as a rectifier.

The grid bias of the Pentode is obtained by the center tap of the Rectifier Plate passing through the 1620 ohm field coil to ground instead of leading direct to ground for negative potential. The power grid is tapped into the field coil at 1320 ohms or 300 ohms from ground, making a positive flow to ground. The resistances are so arranged in the grid circuit of this power tube, that it gives excellent tone quality because it presents a constant positive flow to ground of circuit.

A 385 ohm filter choke connects the source of the plate or 280 filament with the plate filter by passes which are of the 8 mfd wet electrolytic type condensers and the remainder of the circuit being by-passed by paper and mica condensers.

The first electrolytic condenser by-passes the plate positive source to the center tap of the rectifier plate winding or negative potential which will have a negative voltage of approximately 83 volts before it passes through the field coil to ground. The body or negative of the electrolytic case being insulated from the chassis permits this by-passing arrangement.

GENERAL MOTORS RADIO CORP. MODEL 120, 130, 140

Service Notes

MODELS 120, 130 and 140 CHASSIS MODELS "A" and "B"

The Models "A" and "B" chassis are divided into three groups having slightly different circuits.

Serial Numbers below 29100A and 1700B:
In the original models, with serial numbers below approximately 29100A and 1700B, one side of the Dual Volume Control is in the antenna circuit between the antenna and the first R. F. coil, with a .0005 mfd. condenser between the antenna and the antenna choke.

The other side of the volume control, together with a 5000 Ohm resistor is in the screen grid circuit of the R. F. stages. In these sets there are two R. F. chokes in the cathode circuit of the R. F. tubes.

Sets with this circuit can be distinguished by the presence of five similar R. F. chokes, one being located near the first 224 tube socket, and four between the second and third 224 tube R. F. Coil Shields.

Serial Numbers between 29100A and 62100A, Model "B" Chassis:
The circuits of the Model "B" (25 cycle) chassis are the same as those of Model "A" (60 cycle), except that one 1.0 mfd. condenser, Part No. 1200160, is added in parallel with the power choke.

The other side of the volume control in these sets is in the cathode circuit of the three R. F. Stages. The two R. F. chokes in the 224 cathode circuits are not used, but three 1250 Ohm resistors are used, one in series between the cathode of each 224 tube and the volume control.

Electrolytic Condensers:
To test the Electrolytic condensers used in chassis above 62100A and 1964B use an "Open Test" or "Continuity Test" meter with a 22 1/2 volt battery. It should be noted that by reversing the test leads, different readings will be obtained. The condenser to be tested should be removed from the chassis and tested as follows:

Pos. Test Point	Neg. Test Point	Correct Reading
Center Terminal Condenser Can	Condenser Can Center Terminal	Hand Should Jump and Return Hand Should Rise Slowly, Almost to Full Scale

If both readings are the same, the condenser is defective and should be replaced. When in doubt try replacing the condenser.

Trimmer Adjustment on Tuning Condensers:

A small Trimmer Condenser is located on each of the four variable condenser units which comprise the Gang Tuning Condenser. The trimmer screws may be adjusted by means of screw-driver, through the holes in the top of condenser shield.

The No. 1 Trimmer (Left side when viewed from the front) should be adjusted when the set is installed as it balances the antenna stage to meet the requirements of the antenna used. This Trimmer should be adjusted by tuning a station whose frequency is at the high end of the scale near 1400 Kilocycles. No. 2, 3, and 4 Trimmers should be adjusted only when the complaint is very definitely lack of volume or broad tuning. If the sensitivity or selectivity is not normal, the Trimmers should be adjusted before attempting to calibrate the Tuning Condenser. To adjust the Trimmers, tune in a station around 1400 Kilocycles and turn the volume down by means of the volume control until the station is just audible. Start with the Trimmer which is on the left side of the chassis, when viewed from the front, and adjust the screw either to the right or left until the loudest signal is obtained. This adjustment should bring the receiver back to normal operation. If not, the Trimmer on the right should be adjusted in the same manner. The two center trimmers should not be adjusted except in rare cases, and extreme care should be taken when adjusting these Trimmers so that the selector Pointer will not be thrown off adjustment and read incorrectly.

Condenser Adjustments:
If the selector pointer will cover only 1500 to 600 Kilocycles on the selector strip, the two-fingered washer has become bent so that the stop washer will slide over it. To correct this, remove the selector shaft assembly and invert the flat, two-fingered washer.
If the Pointer washer will not trip, set the selector pointer at 1460 Kilocycles, loosen the set screws holding the switch lever and turn the switch lever until it just engages the switch. Tighten the set screws in this position.

Selector Strip Adjustment—Mechanical:
If the selector pointer appears to be off mechanically, i. e., if a station close to 700 Kilocycles is off 1/2 inch and a station close to 1400 Kilocycles is also off the same amount, the adjustment of the selector strip to log one station would bring them all into line.
To make such an adjustment, tighten all set screws, then tune in a station of known frequency. Reduce the volume by means of the volume control so that the selector can be set on the exact peak of the incoming wave. Loosen the screws holding the selector strip and shift the strip until it indicates properly the frequency of incoming signal. If the selector frequency cannot be shifted far enough, loosen the set screws by which the selector windshield is attached to the selector shaft, and shift the pointer to its approximate position before shifting the selector strip.

Selector Adjustment—Electrical:

The adjustment of the selector electrically, is known as "logging". If it becomes necessary to re-log the set, tune in a station between 660 and 700 Kilocycles, preferably as close to 650 as possible, which is known to be broadcasting exactly on its assigned wave length. Set the selector pointer to log this station accurately as described in the preceding paragraph.

Then set the pointer on the exact frequency of a station known to be operating at that time between 1350 and 1500 kilocycles. Adjust the volume control until the station is just audible, without moving the pointer, adjust the left trimmer condenser (viewed from the front of the chassis) until maximum volume is obtained. Repeat the operation on the remaining three trimmers, one at a time, going from left to right until the station is peaked exactly on the correct reading.

Now try the station which was used to set the low frequency point and if it logs properly, all other stations will be in line. If the station does not log properly, repeat the above operation.

Hum:

If the No. 245 Tubes are unmatched, or if one or the other is defective, a hum will result which is very similar to what is known as 60 cycle hum. This can be eliminated by replacing one or both of the No. 245 Tubes.

It is to be understood that the No. 245 Tubes may not necessarily be defective. They may operate satisfactorily in another set, but may be merely unmatched with respect to each other.

The No. 227 Detector Tube will sometimes cause a similar trouble, except that the No. 227 Tube causes more of a buzz than a hum. If this buzz or hum cannot be eliminated by switching the 227 Tubes, the defective Tube should be replaced.

Volume Control:

Many complaints of unsatisfactory volume control action are not caused by defective volume controls, but in reality the faulty action is due to variation in the cut-off point of the No. 224 screen grid tubes. It is necessary to have, in the first R. F. stage at least, one tube which has a low cut-off point.

If the complaint is not due to a volume control which is actually defective, it usually can be eliminated by switching the No. 224 tubes from one socket to another until the proper arrangement is obtained.

In chassis with serial numbers between 29100A and 62100A (also 1700B and 1964B) a 7000 Ohm Resistor (Black and Blue) is connected between the cathodes of the screen grid tubes and ground, in parallel with one side of the volume control. When near a powerful local broadcasting station, the volume control, because of this resistor, may not cut the volume down low enough. This can be improved by removing the resistor mentioned. This is resistor No. R-21 shown in the wiring diagram

COMBINATION MODELS No. 150 & 160.

MODEL 150,160,
Pick Up-Trans.
Service Notes.

GENERAL MOTORS RADIO CORP.

PART 1. THE ELECTRIC PICK-UP & TRANSFORMER (Continued)

Description:
The electric pick-up provides an electrical means for sound reproduction. The pick-up is composed of three major parts:

1. A permanent magnet.
2. A small generating coil.
3. A vibrating armature which is caused to vibrate by the phonograph needle.

The generating coil is located in the center of the field of the permanent magnet which causes a constant flow of magnetic lines of force through the coil. In order to generate current in the coil, it is necessary to vary the strength of the magnetic field. This is accomplished by placing a vibrating armature in the center of the coil with a needle inserted in the needle holder.

The needle rides in the grooves on the record and as it vibrates back and forth it also causes the armature to vibrate. By the vibration of the armature in the magnetic field, the field strength is varied accordingly and a pulsating current of electricity is generated in the coil. The pulsations of this current correspond to the sound waves of the music, but they are too weak to be audible in the speaker.

The generating coil is connected, through a volume control, to the radio wiring and the electrical pulsations are amplified many times by means of the radio amplifying tubes.

When the pulsations of current generated in the generating coil have passed through the amplifying tubes, they are carried to the speaker unit where they set the diaphragm in motion which generates audible sound waves in the air.

- Pick up Transformer - Part No. 1,200,877
- Cord Assembly - Part No. 1,200,866
- Choke Coil - Part No. 1,200,869
- Condenser - Part No. 1,200,418

(Cord Assembly Part No. 12,001,194 used on Models 150-A and B -)

The advantages of this method of reproduction are the ease with which the volume of sound may be varied by the volume control which varies the strength of the electrical pulsations before delivery to the amplifying tubes, and the truer reproduction through the radio speaker.

Adjusting Vibrating Arm:

Place a good needle in the needle holder and a record on the turntable. Turn the power switch on and the selector pointer to the right until the Phono-switch trips. After the tubes have had sufficient time to heat properly, tap the needle lightly with your finger, first on one side and then on the other. Each time the needle is tapped, a click should be heard in the speaker. If the click is louder when striking the needle on one side than it is on the other, the pick-up is out of adjustment. Remove the metal cover from the pick-up and note whether the vibrating arm, which is operated by the needle, is directly

Figure 1

in the center of the space between the two pole pieces.

If the vibrating armature is off center, loosen the two brass round head screws which hold the small brass plate in position on the pole pieces. Center the armature between the pole pieces and tighten the brass screws securely.

Testing for Open Coil or Wiring:

If there is no click at all, when tapping the needle, put the pick-up in place on the record and allow the record to rotate. Place the terminals of a set of ear phones on the two connections of the volume control to which leads from the pick-up connect. Reproduction of the record should be heard faintly.

Provided no sound is heard, remove the pick-up leads from the volume control and check for open circuit in those leads and the pick-up. (Note: Inspect the contacts on the pick-up end of the leads, to insure good contact in the socket on the pick-up.)

Repair Instructions:

Pick-ups that cannot be adjusted properly or that have open coils, should be replaced with new ones and the old ones returned to the nearest service station for repair.

Next Step if Pick-Up is O. K.:

If reproduction of the record can be heard faintly through the ear phones, check the volume control or the connections between the pick-up and the radio unit for the trouble.

Testing Pick-Up Transformer:

Figure No. 2—Pick-Up Wiring Diagram

Figure 3

Make the following tests with an open test meter. (See Figure 3 for contact numbers.)

From Contact Number	To Contact Number	Expected Reading	Insulation Reading Called for

3	5	Full Scale	Open Choke
Cond. Lead from No. 4	5	*Hand should jump and Return to Zero	Shorted or Open Condenser

*The Condenser Lead must be disconnected from No. 4.

GENERAL MOTORS RADIO CORP.

MODEL 150,160
Disc Motor
Service Notes

COMBINATION MODELS No.150 & 160

PART 2. INDUCTION DISC MOTOR

Description:

The motor consists of an induction disc of aluminum arranged to revolve between the poles of two sets of field magnets. The coils of the field magnets, commonly called field coils, receive current from the house lighting circuit and are the only parts electrically connected to that circuit.

Figure 4—Wiring Diagram of Induction Disc Motor

The main shaft of the motor operates in a vertical position, is supported at the bottom by a single ball bearing, carries the induction disc and turntable, and drives the governor shaft through a set of gears. The speed of the shaft is controlled by a mechanical fly ball governor.

The induction disc motor has no commutator, slip rings, or other moving electrical contacts, and this, with the natural slow speed, makes it very well suited for the service for which it is used.

Servicing:

Any servicing which the motor may require is in general, of a minor nature, and in most cases, adjustments will be mechanical rather than electrical. Two of the most common causes of motor failure are incorrect power voltage and lack of lubrication.

Power Voltage Variations:

High voltage will cause the motor coils to heat excessively and thus destroy the insulation and dry the lubrication.

Low voltage will cause a lack of power and unstable operation. When servicing the induction disc motor, always check the power line voltage at the socket to which the motor is connected and, if possible, while the motor is running. This voltage should be between 105 and 120 volts A. C.

Lubrication:

It is important that the motor be lubricated at least once every six months with the proper

PART 2. INDUCTION DISC MOTOR (Continued)

Figure 5

core and coil assembly may be taken off by removing the three screws holding the coils to the frame and top plate.

When the coils are replaced, be sure that the wire terminals marked with the same letter are placed together. That is, 1A, 2A and 3A must be attached to the terminal strip at the point "A", etc. See Figure 5.

Failures to Maintain Constant Speed:

There are four points to be checked if the motor fails to maintain constant speed.

Hardened or Gummy Lubrication. Examine the moving parts. If necessary, remove them and wash with kerosene. Replace the parts and lubricate them.

Shifting of Motor on Motor Board. In some cases a slight shifting of the motor on the motor board during shipment will cause binding. Loosen the three motor screws, and retighten, alternately, while the motor is running until the binding has been eliminated and the motor runs steadily.

Weak Coils. If the lubrication and mounting of the motor have been examined as described above, and the condition still exists, replace one

or both of the motor coils as described under subject "Motor Does Not Operate."

Mechanical Causes. All the points mentioned in subject entitled "Reducing Mechanical Noise" of speed and should be taken into account even though there is no actual mechanical noise present.

Reducing Hum: There are a number of causes for hum in the induction disc motor, but in most cases any existing hum can be eliminated by proper adjustment.

Loose Coil Winding on Iron Core. The condition can be corrected by forcing a small wooden wedge between the outside of the coil and the core. It may be necessary to wedge both the upper and lower sections of each coil.

Coil Loose on Top Plate. The three screws holding the coil on the top plate should be tightened securely.

Loose Laminations of Iron Core. The bolts clamping the iron laminations together should be tightened securely. In some cases, however, it may be found that the hum can be minimized by adjusting the tension of these bolts.

COMBINATION MODELS No. 150 & 160

PART 2. INDUCTION DISC MOTOR (Continued)

Motor Not Fastened Securely to Motor Board. Make certain that the nuts holding the motor to the motor board are fastened securely and with equal tension and that the felt washers between the motor and the motor board are not injured.

Motor Not Properly Secured to Cabinet. In many cases motor hum can be eliminated or minimized by adjusting the four screws which hold the motor board to the cabinet. Placing a piece of felt between the motor board and the motor board rail will often help to eliminate hum.

Reducing Mechanical Noise: There are several features which may cause motor noise other than a hum.

Governor Springs. A noise or rattle may sometimes be caused by loose or broken governor springs. Tighten all the governor spring screws. If this does not stop the noise, loosen the screws on the disc end of the governor springs and allow the motor to run for a minute or so to allow the springs to assume their correct position. Stop the motor and retighten the screws. If any of the springs are broken or badly out of balance, they should be replaced. Removal of the governor can be accomplished by loosening the two governor bearing screws, one at each end of the shaft, and lifting the governor from the frame.

Governor Thrust Bearing. The thrust bearing at the disc end of the governor may sometimes cause noise while the motor is running. Hold one finger over the end of the bearing and loosen the set screw which holds the bearing in position. Adjust the bearing to the most quiet running position, and retighten the set screw.

Governor Spindle. A bent governor spindle will cause binding in the gears and bearings as well as a noise. The bent spindle should be replaced with a new one.

Governor Driving Gear. Remove the turntable spindle as described above and examine the gear for wear. If the wear on the teeth is greater on one side than on the other, the turntable spindle is bent and should be replaced. The gear should also be replaced.

Turntable Spindles and Disc. A bent turntable spindle or a bent or improperly adjusted

PART 3. THE AUTOMATIC SWITCH & BRAKE

Description:

The automatic switch and brake consists of a system of cans and levers operating in such a manner that the movements caused by the eccentric groove at the end of the record trips the switch, forcing a friction leather against the turntable and, at the same time, cutting off the power to the motor.

Service:

The switch will ordinarily require no adjustment. In some cases, however, the upper spring shown in Figure 6 may become bent upward far enough to prevent the contacts from coming together when the hand lever is turned.

Figure 6

When such a condition is found, bend the upper spring down until the contact points make a firm contact when the hand lever is turned on. When replacing the switch on the brake plate, care should be observed in properly locating the switch on the plate, so that the switch will make and break contact when the hand lever is turned on and off. The two adjusting screws can be loosened and the switch moved in the slot until the correct position is located. When the hand lever is in the off position, the contact points should be at least 1/16 inch apart to prevent excessive sparking when the switch is turned off.

Adjustments:

The following adjustments will eliminate a majority of the troubles encountered:

1. Switch Fails to Trip. Bend the lug B (Figure 7) so that there will be less contact at point A.

Failure to trip may sometimes be caused by a loose trip arm. Make certain that all screws of this assembly are tight.

2. Switch Trips Before the Completion of a Record. Bend the lug back, so that there will be more contact at point A. (Figure 7.)

Warning: Do not bend the lug too far, as bending too often in opposite directions will snap off the lug

Figure 7

3. The two surfaces at the point A must be square. If they have become worn round, they should be squared with a fine file.

4. If the switch lever 1 swings with the eccentric groove, but the friction lever 2 fails to swing, or swings but slightly, the latch trip 5 is probably caught in a burr on one of the teeth of the latch plate 12. Rub the teeth of the latch plate with a piece of emery cloth, taking off any burrs that may be present.

5. If the latch trip does not engage with the latch plate properly when the tone arm is swung to the starting position, loosen the screw 11, adjust the plate 12 the required amount, and tighten the screws.

Note: The adjusting of the latch plate has nothing to do with the tripping of the latch.

6. If the brake does not stop the turntable soon enough the condition can be remedied by one of the following:

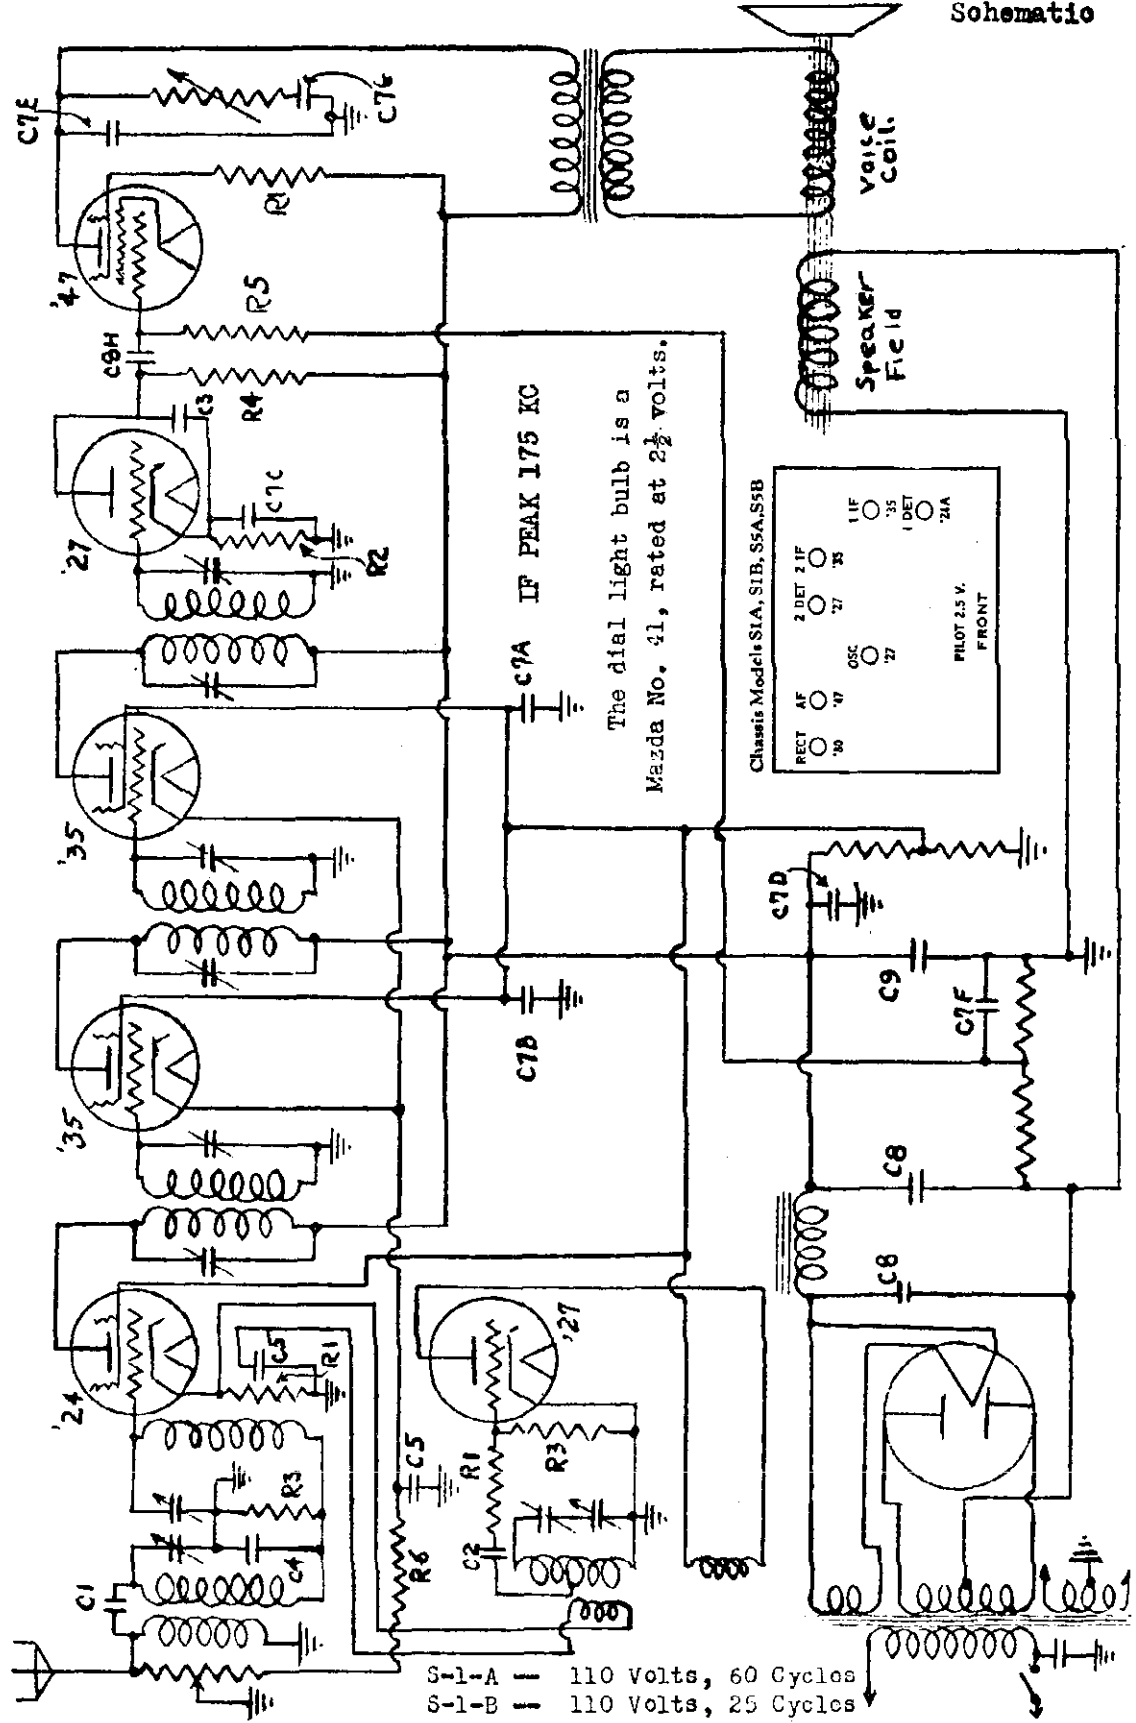

- a. Examine the friction leather, making certain it is not worn down too far to make proper contact with the inside rim of the turntable.
- b. Increase the tension of the spring 9 (Figure 7) by cutting off one or more of the coils and then replacing the end of the spring over the lug.

7. If the latch 14 does not strike the lug A when the hand lever is pulled to the ON position:

- a. Increase the tension of the spring 13 in the same manner as described above in "B" of 6.
- b. Decrease the tension of the spring 4 by stretching the coils if necessary

ANTENNA AND GROUND CONNECTIONS

On Models 216, 217 and 219 a special antenna is installed in the cabinet and an antenna and ground terminal strip with three clips is located, on the bottom of the speaker baffle board.

If an outside antenna and ground are used, connect the antenna lead-in wire to the clip marked "A" and the ground wire to the clip marked "G". The jumper wire provided should connect clips marked "G" and "X".

If the local reception special antenna in the cabinet is used, connect the special antenna lead to the clip marked "A". The jumper should connect clips marked "G" and "X".

If the power line is to be used as an antenna, simply connect clips "A" and "X" by means of the jumper. If possible connect a ground wire to clip marked "G".

MODEL 220
(S-10A, S-10B)
Trimmer Notes

GENERAL MOTORS RADIO CORP.

PEAKING THE I.F. STAGES

CONNECTIONS

(1) Connect the test oscillator to the control grid of the first detector tube, with a fixed .002 Mfd. condenser connected in series between the test oscillator and the grid terminal of the tube. The grid cap and lead must be left in place on the tube. Connect the GND terminals of both the test oscillator and the receiver to a common ground.

NOTE: DO NOT CONNECT TO THE GRID OF ANY OTHER TUBE BECAUSE IT WILL CHANGE THE BIAS VOLTAGE OF THE SET.

If the test oscillator has a dummy antenna which cannot be disconnected, connect a 1 megohm resistor between the test oscillator output terminal and ground.

(2) Remove the 227 oscillator and the 227 A.V.C. tube and plug the dummy oscillator and A.V.C. tubes in their sockets.

TRACKING PROCEDURE

(1) Feed a signal of exactly 1400 K.C. into the chassis from the test oscillator.

(2) Screw all parallel trimmers down tight and then adjust the oscillator parallel trimmer condenser to obtain a maximum output.

(3) Adjust the remaining parallel trimmer condensers to obtain maximum output.

NOTE: Models S10A or S10B chassis do not employ an oscillator series condenser. It is not necessary to make the tracking adjustment at 580 K.C.

Rectifier	G-80	5.0	250		54	...							

*This cannot be measured with the customary 1000 ohm per volt meter because of the high resistance between the grid and ground. If there is any doubt about the pentode bias, check the 100,000 ohm, 1 megohm, 200,000 and 300,000 ohm resistors and .25 M.F.D. Condenser in this circuit and be sure the speaker field voltage is correct, 112 volts. Also measure the pentode plate and screen voltages and if they are 250 volts, the plate current should be 32 M.A.

**This should rise to 42 when the volume control is turned to minimum.

ISSUE 3 11-12-34

Radio-Phonograph Switch

Both the COLLINGWOOD and ABBEYWOOD Models have a radio-phonograph switch which is located below the central control or station selector. This switch is turned to the right for radio operation and to the left for phonograph operation. There are pick-up terminals on the Model 35 chassis employed in both these sets, although the COLLINGWOOD Model is not a combination receiver. There should always be a jumper across the pickup terminals when the pickup is not attached.

Power Supply System

The power supply system of the Model 35 chassis consists of a power transformer, G-80 rectifier, a filter choke which is tuned to hum frequency, a 4 mfd. paper condenser, and two 8 mfd. electrolytic condensers. The condenser employed across the filter choke is a .15 mfd. for sixty cycle operation, and a .35 mfd. for twenty-five cycle operation. The output from this filter section passes through the fields of both dynamic speakers which act as additional chokes to the filter circuit.

MODEL 25-B
MODEL 35
Alignment

Technical Data
Models 25B and 35 Chassis

Procedure for Alignment

WARNING: The Power Line shall never be connected to the receiver until the speaker and tubes are connected in the receiver.
The receiver shall be aligned with the volume control set at maximum and input reduced to keep output below 1 watt.

1. Supply 175 K.C. on 1st detector grid and adjust all I.F. tuning condensers to give maximum sensitivity.
2. Set dial at 1500 K.C. and line up all radio frequency circuits on 1500 K.C. signal for maximum output.
3. Set dial at 550 K.C. and adjust oscillator tracking condenser for maximum sensitivity with 550 K.C. feeding into the set. For each adjustment of the oscillator tracking condenser, there will be a different dial setting for maximum sensitivity. The combination of tracking condenser adjustment and dial setting which gives maximum sensitivity, disregarding calibration is the correct adjustment. If this adjustment falls within 5 K.C. of the 550 K.C. calibration point, readjust trimmers at 1500 K.C. and check dial calibration at 1000 K.C.

Each Receiver Must Be Aligned for Maximum Sensitivity. Check volume control throughout its range for noise, open or short circuit and irregularity of control operation. Check acoustic control over entire range for noise, open, short circuit and operation.

Automatic Volume Control System

The manual control is a 6,000 ohm potentiometer between second detectors and output tubes, operating entirely independent of the automatic control.

Automatic control is accomplished by applying the second detector grid bias on the R.F., Detector and I. F. Stages to control their amplification, and by the inherent control of audio amplification in the second detector stage, due to the same bias.

Sensitivity

In cases where low sensitivity is encountered, the first step taken to remedy the condition, should be to check the G51S Tubes, which may be drawing abnormal grid current. This procedure should always be taken prior to any attempt to remedy by aligning the condenser gang.

Method of Biasing

The necessary bias obtained on the R. F., First Detector and I. F. is obtained from a bleeder circuit. The Oscillator is self-biasing with grid current drop across the 100,000 ohm grid resistor. The second detectors are self-biasing from a grid current drop across the 250,000 ohm grid resistor. The pentodes are also self-biasing by the 110 ohm wire-wound resistor in the filament circuit.

"Off" and "On" Line Switch

The "Off" and "On" Line Switch is attached to the volume control shaft. Turning the volume control completely to the left shuts the receiver off. The first fifteen degrees rotation of the control to the right will turn the receiver on. The balance of rotation to the right controls the volume of the receiver.

Models G-10-C, G-13-B, G-14 and G-14-B Dynamic Speakers
Employed in Models Collingwood and Abbeywood

Both the COLLINGWOOD and ABBEYWOOD Models are equipped with twin speakers. The COLLINGWOOD Model employs the G-10-C, a small dynamic speaker (field resistance 200 ohms) for the high notes and the G-14, a large dynamic speaker (field resistance 750 ohms) for the low notes. The ABBEYWOOD Model employs the G-13-B dynamic speaker (field resistance 300 ohms) for the high notes and the G-14-B dynamic speaker (field resistance 550 ohms) for the low notes. The voice coil of the G-14-B is excited by one-half of the secondary of the output transformer which is located in the base of the speaker, and the voice coil of the G-13-B is excited by the other one-half of the same secondary. These speakers operating simultaneously produce an almost flat audio frequency response curve that gives these receivers a truly faithful reproduction.

Models G-11-B and G-13 Dynamic Speakers

Employed in Models Cheltenham, Brentwood and Brucewood

The Models G-11-B and G-13 Dynamic Speakers have a field resistance of 570 ohms at 78° F. The G-11-B Speaker which is employed in the Cheltenham Model, has a field structure of heavy "U" construction, and a 9.5" paper weight cone which responds readily to the slightest excitation. The output transformer with its terminal board is rigidly fastened to the cone housing. The G-13 speaker, which is employed in the Brentwood and Brucewood Models, has a field structure of heavy "U" construction mounted on a 6" base which is also used as a case for the output transformer. The 12" cone is a special made paper weight cone which responds readily to the slightest excitation.

MODEL 353
Record Changer
Notes

GRIGSBY - GRUNOW CO.

Instructions for Care and Operation of Automatic Record Changer Employed in the Majestic Model 353 Receiver

IMPORTANT.—The following instruction should be used in operating the MAJESTIC Automatic Record Changer employed in the Model 353 Abbeywood Receiver.

WARNING.—Before attempting to operate the automatic record changer, three screws which pass through the base plate of the record changer and the wood shelf, should be loosened so that the chassis is resting freely on the rubber cushions.

WARNING.—At no time for any reason should the turntable be stopped by hand. If this warning is not adhered to, serious damage may result.

RECORDS.—It is possible to play the two types of records available for home entertainment, that is, the ordinary records and the new long playing records. Each of these two types can be obtained in both twelve and ten inch diameter. The approximate playing time of these records is as follows:

Ordinary Records.
10 inch—2½ minutes.
12 inch—3½ minutes.

New Long Playing Records.
10 inch—10 minutes.
12 inch—15 minutes.

SPEED.—The standard record turns at a speed of 78 revolutions per minute, whereas the long playing record turns at the rate of 33 1/3 revolutions per minute. The mechanism is provided with a speed control lever to give either of these speeds, as required.

SWITCHES.—The line switch for the phonograph motor is located near the front of the turn table.

Directly under the main tuning dial is the "Radio-Phonograph" switch, which should be thrown to phonograph position for record playing. The line switch for the radio receiver is incorporated in the volume control assembly, which is located to the left of the phonograph switch.

NEEDLES.—The long playing records should be played using only the special needles designed for this type of record. After the special needle has once been removed from the pick-up head, do not use it again. Replace with a new one.

Do not play ordinary records with the special needle designed for long playing records.

Instructions for Setting Selector Device

It will be noted that to the right of the turn table there is a selector lever for the purpose of playing ten inch records automatic, ten inch records repeat, twelve inch records repeat, and universal or manual operation.

10" AUTOMATIC.—This is the only position in which the ten inch records are changed automatically.

10" REPEAT.—In this position, the mechanism will repeat the playing of the same record as many times as desired.

12" REPEAT.—The mechanism in this position will keep repeating a 12" standard record. Do not, however, attempt to repeat a 12" long playing record as it should be played manually with the lever in the universal position.

"UNIVERSAL."—In this position, the automatic changing and the repeat mechanism are not in operation, and the playing is controlled manually as with the ordinary phonograph. This position should always be used for playing the 12" long playing record and may be used for playing standard records.

Instructions for Operating Automatic Record Changer

Select the desired records and place them carefully in the record holder or magazine. The record at the bottom of the magazine will be the first one to be played.

The automatic changing magazine handles from one to ten of the 10" records. Do not mix standard records with long playing records in the magazine for automatic playing, as each type requires a different speed and a different type of needle.

It is best to place the first record on the table by hand and start the needle very carefully in the first groove with the selector lever in the "Universal" position; then the lever may be turned to the automatic position if desired, after which the changer will operate as outlined in paragraph II under "Instructions for Setting Selector Device." This procedure protects the needle and the record, and assures longer life for both.

REJECT LEVER.—While playing in the automatic position, if it is desired to interrupt the record and to play the following one, pull forward the reject lever which is located to the right of the turn table. This will cause the mechanism to go through a complete cycle of changing the record.

RELOADING.—When all of the records have been played through, and the magazine is empty, the mechanism will repeat the last record over and over. In reloading the magazine, switch off the motor at the time the magazine has travelled to the extreme left position, and carefully remove the stack of records from the turn table. Then replace them in the magazine in any desired sequence, with the side facing up which you desire to play. *The magazine may be swung up and down, but do not try to force it sideways manually.*

ARM REST.—When changing records, the pick-up should be placed on the rest, to the right. If it cannot be placed there without straining, this is a sign that the automatic mechanism has not completed its cycle. In this case, hold the pick-up loosely, turn on the motor switch and wait until the record magazine has moved to the extreme left, which will allow the pick-up to be placed on its rest.

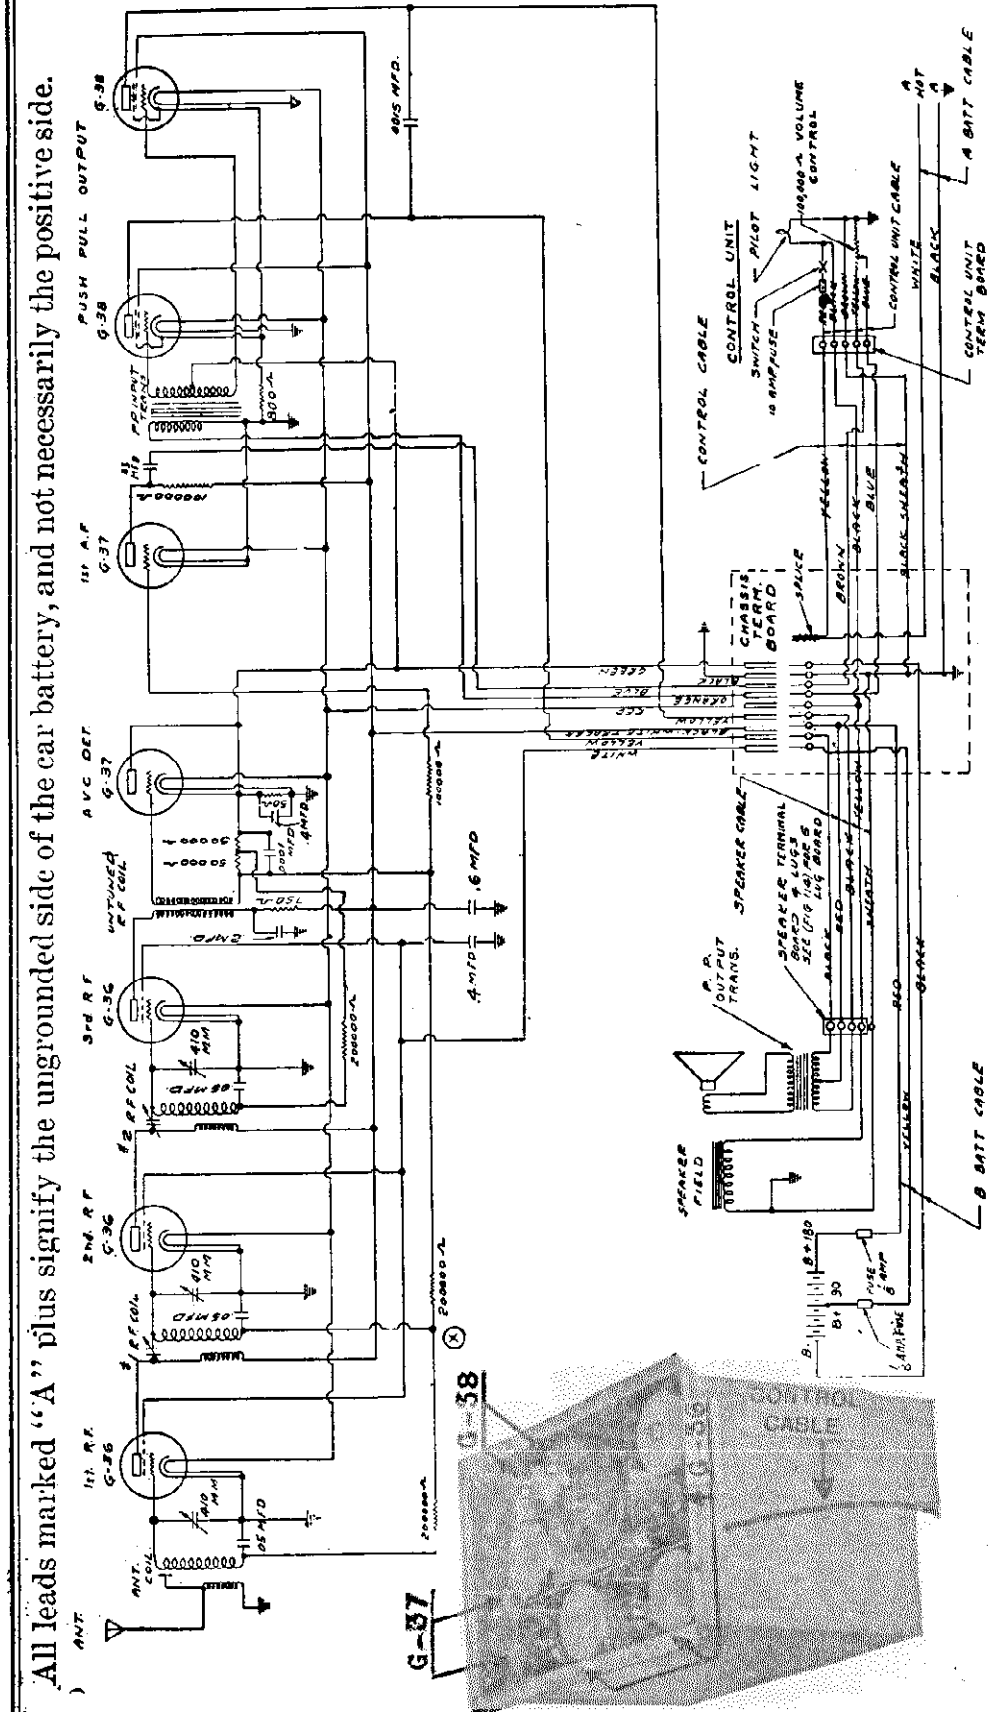

Instructions for Operating Manually

By placing the lever in the "UNIVERSAL" position, the records will be played manually. The 12 inch long playing records should always be played in this position.

Oiling

Every two or three months, the turn table should be removed and three or four drops of oil placed in each of the six holes provided.

GRIGSBY - GRUNOW CO.

Note on Alignment of Gang Condenser: Should a receiver need realignment in the field, a station should be tuned in at approximately 1300 kilocycles and the alignment made in the usual manner. In case one alignment condenser will not indicate a peak of sensitivity, slightly advance or retard the tuning control and proceed to readjust the alignment condenser as before.

Note on Automatic Volume Control System: The Model 110 chassis utilizes an automatic volume control system in combination with a diode detector, the G-57 detector serving both functions.

Notes

GRIGSBY - GRUNOW CO.

120 CHASSIS

I. F. Transformers Alignment

1. Connect oscillator for intermediate frequency alignment and set it in operation.
2. Align each aligning condenser on the intermediate frequency transformers to give maximum signal output.
3. After all four condensers have been aligned at 175 kilocycles, this stage should not be again adjusted.

R. F. and Oscillator Alignment

1. Tune in station in the vicinity of 1,500 kilocycles, or put output of local oscillator (if available) into receiver
2. Align R. F. stages and oscillator tuning condenser. The position of these condensers is shown on illustrated photograph in this manual.

Oscillator Tracking Condenser Alignment

1. Tune in local oscillator to 600 kilocycles.
2. Adjust both tuning control and tracking condenser simultaneously to give maximum signal as noted on output meter. This will be obtained by rocking tuning control across resonance point while adjusting tracking condenser to give maximum output at the point of resonance. This operation cannot be performed without local oscillator and output meter.

Check

Check the alignment previously made of R. F. and oscillator aligning condensers in the vicinity of 1,500 kilocycles.

POWER TRANSFORMER

One side of the 110 volt line is connected to the terminal marked Pri. 2" and the other side to one switch terminal on the receiver. The switch completes the circuit to the "Pri. 1" terminal.

The 25 cycle transformer is especially designed for operation on 110 volt, 25 cycle current but may also be used on any 110 volt, A.C. supply having a higher frequency.

Receivers having a 220 volt, 40 to 60 cycle power transformer may also be operated on 110 volt, 40 to 60 cycle current when connections on the primary of the transformer have been changed.

The red and green wires shown in the sketch, (220 volt) must be disconnected and then connected as shown in the 110 volt sketch. No other changes are necessary.

CONDENSERS AND RESISTORS

Three blocks contain the majority of condensers. The choke in the plate circuit of the second detector tube is also contained in one of these blocks. The common leads of condenser blocks No. 1 and No. 2 are grounded. C1, C4, and C6 in block No. 3 have a common lead which is grounded, and the choke and C3 in this block have a common lead connected to the plate of the 2nd detector.

ANALYZER CHART

All voltages taken with a 1,000 ohm per volt voltmeter on the scale indicated in the column headed "Meter Scale." Turn the volume all the way on and connect the antenna and ground leads together. The grid, plate, and screen grid voltages are measured to cathode of the '24 and '35 tubes and to filament of the '47 tube.

The grid voltage on the '27 oscillator cannot be taken except with a very sensitive, low scale voltmeter. The voltage is approximately .05 volts when the A.C. line voltage is 110 volts.

PHONO RADIO INSTALLATION

When phonograph equipment is to be connected to a receiver, the installation should be of a permanent nature. The circuit shown in Fig. 2 is the best possible method of permanently connecting phonograph equipment to this chassis. The circuit consists of a pickup with self-contained volume control, connected in the grid circuit of the second detector tube.

PICKUP AND PHONO TRANSFORMER

To obtain good tone and volume, a pickup with medium or low impedance and a transformer are recommended for use with this receiver. A pickup with high impedance should be used when a transformer is not available.

INSTALLATION

The following parts must be supplied from the factory to make the installation:

- 1 Volume control, Stock No. P-90978
- 1 7,000 ohm Resistor, Stock No. P-90979
- 1 Tip Jack Assembly, Stock No. P-1193

The volume control must be mounted in the same position as the original. The switch is operated by turning the volume control knob to the left as far as possible. The connections on the volume control are the same as on the original.

Removal of the license plate on the rear of the chassis will disclose a slot with small holes at each end. The tip jack assembly should be bolted to the chassis (inside), through the small holes. Bolt the license plate through the small holes, directly above its original position.

Locate the black wire under the chassis, leading from the secondary of the second intermediate transformer. This transformer is directly behind the gang condenser. Disconnect this wire where it is grounded on the chassis and solder the end to the tip jack nearest the center of the back of the chassis. If it does not reach to the tip jack, splice an extra length of wire to it but make the lead as short as possible. Solder and tape the splice so it is firm and well insulated.

Ground the OPPOSITE tip jack on the chassis by soldering one end of a short length of wire on the jack and the opposite end on a lug placed under the nut on the bolt holding the nearest end of the tip jack assembly.

Solder one end of the 7,000 ohm resistor (R17, Fig. 2) to the cathode connection on the second detector tube socket.

Three wires, twisted together and long enough to reach from the switch on the volume control (around the closed ends of the R.F. transformer shields), to the tip jacks are connected as shown in Fig. 2.

Wire No. 1 connects the grounded tip jack and the switch terminal farthest from the center of the volume control.

Wire No. 2 connects the jack on which the black lead from the I.F. transformer is connected, and the raised switch terminal near the center.

Wire No. 3 connects one end of the 7,000 ohm resistor and the remaining open lug on the switch.

When the receiver volume control is turned to the left as far as possible, the S.P.D.T. switch is thrown and opens the circuit from "A" (Fig. 2) to "B" and closes the circuit from "B" to "C."

This action places the pickup in the circuit and connects the 7,000 ohm resistor so that a proper grid bias is obtained for phonograph reproduction.

If a transformer is used, a ratio of 4 to 1 will prove satisfactory. The secondary is connected to the tip jacks and the primary to the pickup cords.

Reversing the pickup leads will determine the correct position in which they should be left. Some pickups have one side grounded and that side should be connected to the grounded pickup jack in the receiver.

If the pickup is disconnected, a wire "jumper" MUST be placed across the tip jacks before broadcast signals may be received. The receiver must never be turned on for even a moment without the jumper in place. A jumper will close the circuit between "A" and "B." This grounds the circuit, thereby placing the proper grid bias on the detector tube, even though the volume control may be thrown to the phonograph position. This jumper may be a piece of solid wire, the ends of which are bent at right angles and plugged into the tip jacks.

ALIGNMENT

A thorough check of the receiver should be made before any attempt is made to re-align any circuits. Examine the antenna and ground connections. Test all the tubes and check all voltages to determine if the failure of the receiver to operate properly is not due to some fault other than mis-alignment. A superheterodyne receiver must be accurately aligned to be selective and sensitive. This receiver has been accurately aligned at the factory and, due to the mechanical design of the gang and adjustable condensers, will not lose its alignment unless damaged by abuse or accident.

A modulated test oscillator and an output meter **MUST** be used when aligning this receiver to insure accurate alignment. It is important that the oscillator deliver a signal at exactly 175 K.C. in addition to frequencies in the broadcast band.

The adjustable condensers which tune the secondaries of the I. F. transformers are located under the hole in top of the shield where the grid lead to the tube is brought out. The condensers which tune the primaries of the first and third I. F. transformers are located under the small hole opposite. The capacity of each condenser is varied by rotating the small adjustment screw under the hole.

A trimmer condenser is mounted over each condenser in the gang and is adjusted by turning the screw located under the hole in top of the gang shield. The shield should not be removed.

The oscillator 600 K. C. tracking condenser is located under the hole in the oscillator unit shield.

Make each adjustment in the order given below or the receiver may be thrown further out of alignment and it will then be a difficult task to align it properly.

The receiver and test oscillator must be well grounded and the output kept within the range of the output meter at all times. All shields must be in place when making the adjustments.

Key No.	Capacity	Lead Color	Lead Color
C22	.5 mfd.	Yellow	Yellow
C16	.5 mfd.	Red	Common Black
C4	.5 mfd.	Blue	Common Black
C8	.5 mfd.	Brown	Common Black
C5	.1 mfd.	White, Green Tr.	Common Black
C2	.1 mfd.	White, Green Tr.	Common Black
C7	.1 mfd.	White, Red Tr.	Common Black
C6	.1 mfd.	White, White Tr.	Common Black
C13	.1 mfd.	Black, White Tr.	White

Referring to sections C6 and C13 in the above list, it will be noted that these have two leads each with the same color code. This was changed in a later model to one lead each, the other lead of each section being connected to the common black lead.

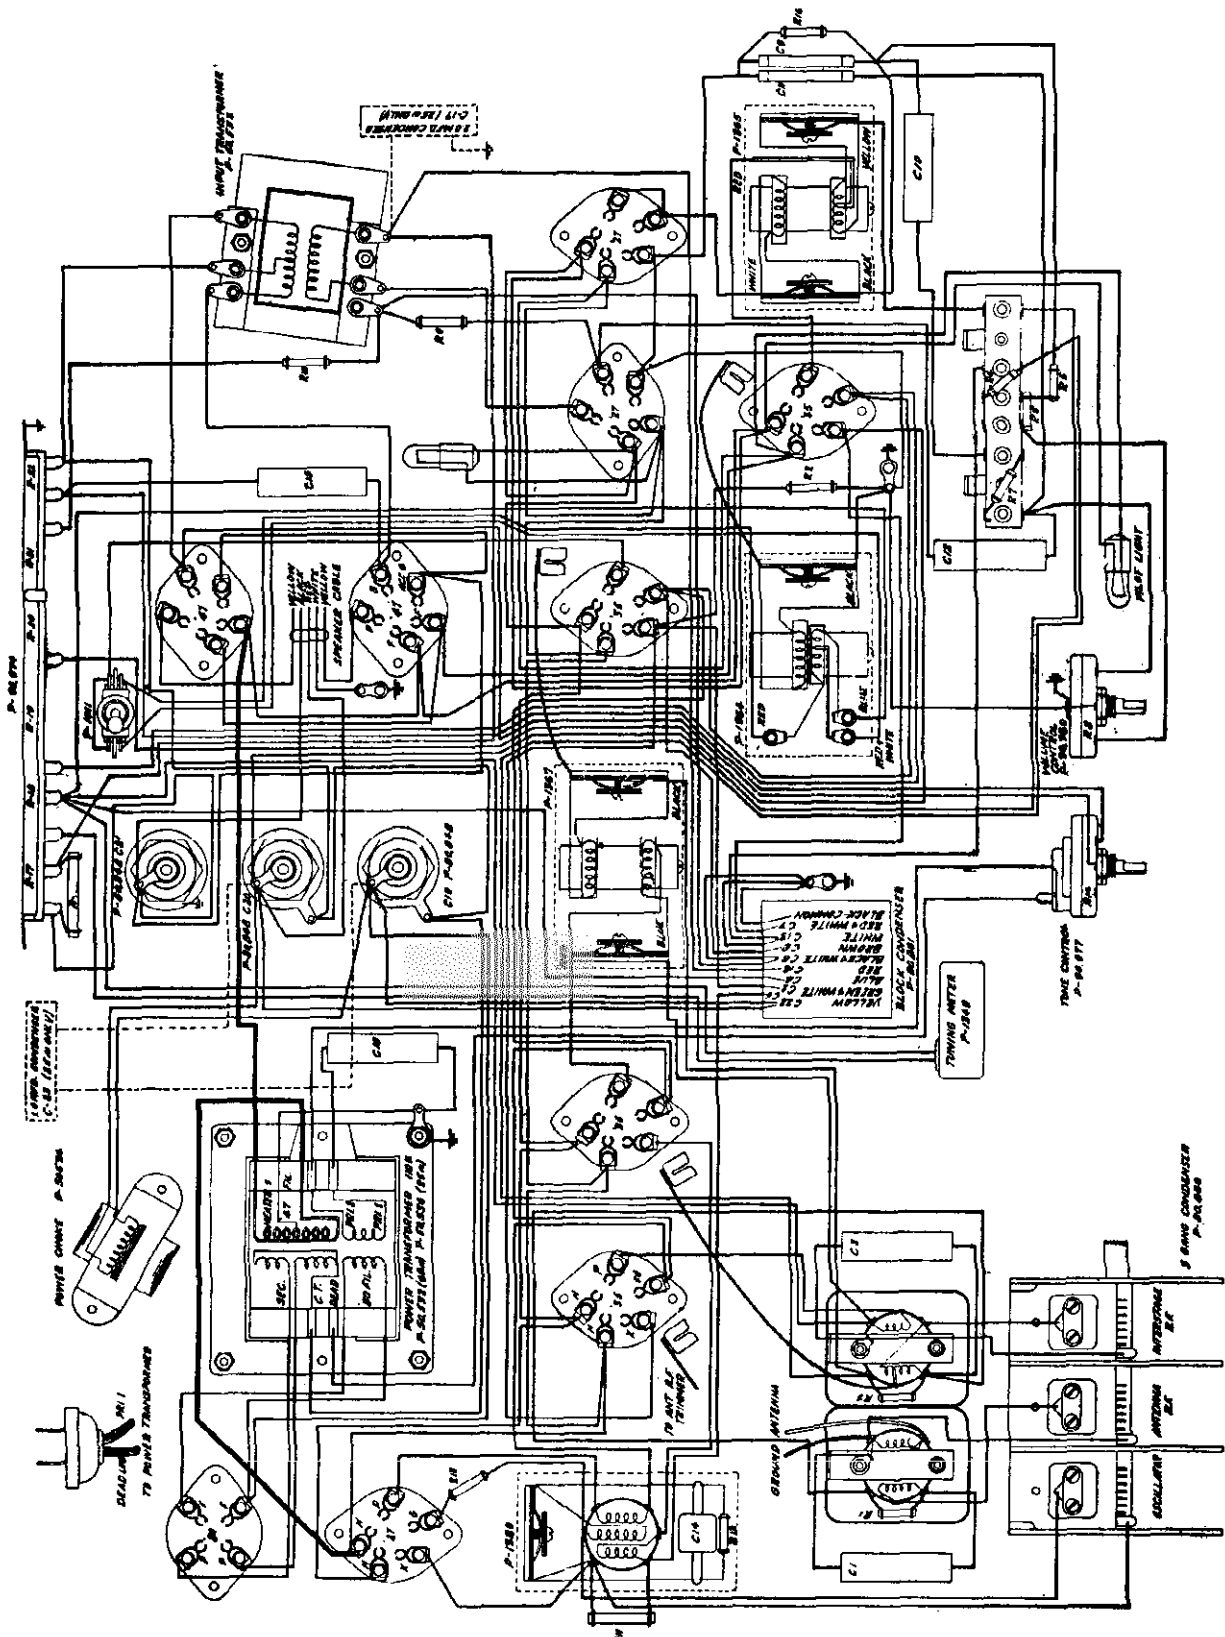

At a later date, two further changes in this condenser block were made. Section C6 which bypassed the grid return of the first I.F. tube to ground was discontinued and section C4 was changed to .25 mfd. These changes bring the block up to date.

The key numbers (C5, etc.) in the above description of the condenser block refer to the key numbers as shown in the schematic circuit diagram of the early chassis. The key numbers of the condenser block as shown in the parts list in the foregoing service manual conform with the key numbers as shown in the schematic of the present chassis, Fig. 1. As explained at the beginning of this supplement, the two sets of key numbers do not coincide.

PHONO PICKUP INSTALLATION

The following parts must be supplied from the factory to make the installation:

- 1 S. P. D. T. Switch, Stock No. P-1011
- 1 Tip Jack Assembly, Stock No. P-1193.

Removal of the license plate on the rear of the chassis will disclose a slot with small holes at each end. The tip jack assembly should be bolted, inside, through the small holes.

Drill a 31/64" hole one inch from the tip jack nearest the center of the rear of the chassis and place the barrel of the switch through the hole with the body of the switch in a horizontal position.

The terminal strip mounted in the left front corner of the base has the resistor, R7. (Red body, green end, yellow dot), connected to the first and second terminals on the end of the strip nearest the center of the chassis. One end of the .05 mfd. condenser, C10, is also connected to the second terminal. See Fig. 4.

Disconnect the resistor, R7, at the second terminal of the strip. Splice a piece of wire to the disconnected end of the resistor and connect the other end of the wire to two terminals, one on each end and on the same side of the switch.

Connect another wire to the terminal where the resistor was disconnected and connect the other end to one of the two open terminals on the switch.

The remaining open terminal on the switch is then connected to the tip jack nearest the corner of the chassis base.

Ground the opposite tip jack on the grounded terminal of the candohm resistor.

Make all wires and connections short, firm, and well insulated.

When the switch is thrown so that the circuit from "A" to "B," is open and the circuit from "B" to "C" is closed, the pickup is then properly connected for phonograph reproduction. The switch is thrown in the opposite direction for the reception of broadcast signals.

Reversing the pickup leads will determine the correct position in which they should be left. Some pickups have one side grounded and that side should be connected to the grounded pickup jack in the receiver.

C6 and C15 contained in the block have one side grounded and the balancer of the condensers in the block, with the exception of C22, have a common lead which is also grounded. C22 tunes the choke in the power supply. C17 and C23 are used in the 25 cycle chassis only, as shown in the schematic diagram.

SERIES 23 SUPERHETERODYNE

POWER TRANSFORMER

Fig. 4 shows the 110 volt power transformer connections. One side of the 110 volt A. C. line is connected to the terminal marked "Pri. 1" and the other side to the open terminal, on the opposite side of the winding, which is in turn connected to one terminal of the switch on the receiver. The switch completes the circuit to the "Pri. 2" terminal.

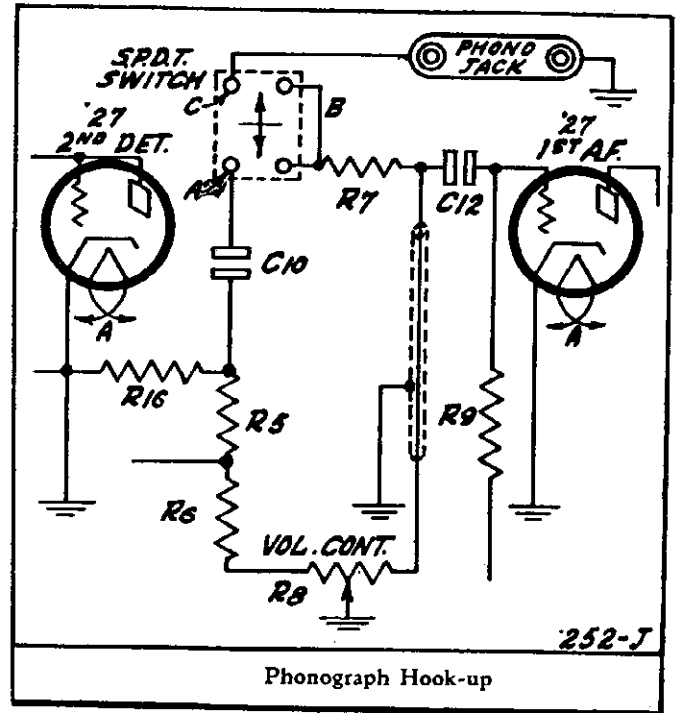

The 25 cycle transformer is especially designed to operate on 110 volt, 25 cycle current, but may also be operated on any 110 v. A. C. supply having a higher frequency, after the condensers C17 and C23 have been disconnected.

Receivers having a 220 volt, 40 to 60 cycle power transformer may also be operated on 110 volt, 40 to 60 cycle current when connections on the primary of the transformer have been changed.

The red and green wires shown in the 220 volt sketch, must be disconnected and then connected as shown in the 110 volt sketch. No other changes are necessary.

Tube	Circuit	Meter Scale	110 V.

2nd A.F. '47	Grid	0-25	15.4
	Accelerating	0-1000	235.
	Grid	0-1000	220.
'80 Rect.	Current (Both Plates)	0-100	108. M.A.
(See below)	Plate to Plate voltage	0-1000	690.

The '80 rectifier plate voltages shown are the totals of both plates, measured from each plate to center tap of high voltage secondary
All voltages taken with a 1,000 ohm per volt voltmeter on the scale in the column headed "Meter Scale." Turn the volume all the way on, connect the antenna and ground leads together and turn the gang condenser plates all the way out. CHECK THE LINE VOLTAGE.

The measurement of grid bias voltages (except on the 47 pentodes) is not recommended, as this causes an abnormal rise in plate current which is injurious to the tube. Further, the measurement of actual grid bias voltages is impossible due to the high resistance in the grid circuits. When the receiver does not function properly and the trouble is apparently due to improper grid bias on any tube or tubes, the cause of the trouble may be determined by applying the proper continuity tests.

CAUTION: IN ORDER THAT THE EFFICIENCY OF EACH TUBE MAY BE COMPARED WITH THAT OF OTHER TUBES OF THE SAME TYPE, THEY MUST NOT BE TESTED IN THE SOCKET IN WHICH THEY ARE USED. TEST ALL '35 TUBES IN THE SECOND I. F. SOCKET AND TEST THE '27 TUBES IN THE FIRST A. F. SOCKET. TAKE THE VOLTAGE READINGS AT THE SOCKET IN WHICH THE TUBE IS USED.

REVISED MODEL

A green paint mark on the left rear corner of a chassis indicates the following changes:

(1) Combination tone control and "On-Off" switch replaced by two separate units. The tone control is mounted and connected as previously but "On-Off" switch is on side of cabinet.

(2) Intermediate transformers assembled together with their adjustable tuning condensers in a round shield. Condensers are adjusted by inserting screwdriver trough the holes provided underneath base, directly below transformer assembly. Early models are adjusted through hole in top of (rectangular) shield

(3) The oscillator coil, its shield, and the 600 K.C. tracking condenser are all mounted separately on the base. The tracking condenser adjustment screw will be found near the left rear corner of the oscillator coil shield. The .0005 mfd. condenser (C14) is not used and the 30,000 ohm resistor (R12) is replaced by a 40,000 ohm resistor mounted between a coil lug and the tracking condenser. The revised oscillator circuit is shown herewith:

The parts affected by the change, are listed below with corresponding parts numbers:

REVISED OSCILLATOR CIRCUIT

MODEL 13
 MODEL 23
 Alignment

GULBRANSEN CO. ALIGNMENT

A thorough check of the receiver should be made before any attempt is made to re-align any circuits. Examine the antenna and ground connections. Test all the tubes and check all voltages to determine if the failure of the receiver to operate properly is not due to some fault other than mis-alignment. A superheterodyne receiver must be accurately aligned to be selective and sensitive. This receiver has been accurately aligned at the factory and, due to the mechanical design of the gang and adjustable condensers, will not lose its alignment unless damaged by abuse or accident.

A modulated test oscillator and an output meter **MUST** be used when aligning this receiver to insure accurate alignment. It is important that the oscillator deliver a signal at exactly 175 K.C. in addition to frequencies in the broadcast band.

The adjustable condensers which tune the secondaries of the intermediate transformers are located under the hole in top of the shield where the grid lead to the tube is brought-out. The condensers which tune the primaries are located under the small hole opposite. The capacity of each condenser is varied by rotating the small adjustment screw under the hole.

Make each adjustment in the order given below or the receiver may be thrown further out of alignment and it will then be a difficult task to align it properly.

The receiver and test oscillator must be well grounded and the output kept within the range of the output meter at all times.

All shields must be in place when making the adjustments.

INTERMEDIATE CIRCUITS

Tune the test oscillator to exactly 175 K.C. and connect its output to the grid of the first detector tube after removing the clip on the lead from the gang condenser.

Adjust the primary and secondary of the first intermediate transformer for greatest volume.

Follow the same procedure on the second intermediate transformer and then turn the receiver off.

Disconnect one end of the speaker voice coil and connect the output meter across the secondary of the speaker coupling transformer. Short the oscillator tuning condenser (in the gang) by grounding the stator plates with a screw driver.

Turn the receiver on and adjust the output until the output meter shows a small or medium scale deflection.

Adjust the primary of the first intermediate transformer for the greatest deflection on the output meter.

Adjust the secondary in the same manner.

Follow the same procedure on the second intermediate transformer and then check the settings of all condensers to make certain the maximum output has been obtained.

When the above instructions have been followed, remove the test oscillator coupling and replace the grid lead on the first detector, and also remove the screw driver shorting the oscillator tuning condenser.

GANG CONDENSERS

Couple the test oscillator output to the antenna, (white wire), on the receiver.

Tune the oscillator to 1400 K.C. and carefully tune the receiver to the signal.

A trimmer condenser is mounted over each condenser in the gang and is adjusted by turning the screw located under the hole in top of the gang shield. The shield should not be removed. Adjust each trimmer condenser for maximum deflection on the output meter.

OSCILLATOR

Tune the test oscillator to 600 K.C. and tune the receiver to the signal. Then after turning the receiver off, disconnect the output meter and replace the voice coil lead which was disconnected.

Turn the receiver on and rotate the adjusting screw on the 600 K.C. tracking condenser under the hole in top of the oscillator transformer shield. Rock the gang condenser back and forth across the signal at the same time and listen closely until the maximum volume is obtained. The tracking condenser is then properly adjusted and remains fixed thereafter.

The receiver should be accurately aligned if the above instructions have been followed and no further adjustments need be made.

* Voltmeter resistance 50,000 ohms. All other voltages measured with 250,000 ohm voltmeter. Chassis is negative for all readings.

IF TRANSFORMER ADJUSTMENT

There are four i-f transformers. Both the grid and plate circuits of each must be tuned sharply to 175 kc. The condenser adjusting screws are accessible from the underside of the chassis; there being two slotted screws protruding through the insulated base of each transformer.

LINE UP OF GANG CONDENSERS

The four sections of the gang condenser function as follows: The first section, looking at the rear of the chassis tunes the selector stage. The second section tunes the grid circuit of the r-f amplifier. The third section tunes the grid circuit of the translator tube and the fourth section tunes the oscillator. The fourth section is that nearest the front of the chassis. The first three must track together at signal frequency, which is the desired signal frequency. The oscillator section on the other hand must track 175 kc higher than the signal frequency.

THE SHORT WAVE TUNER

The short wave tuner consists fundamentally of two tuned circuits and two tubes, one of which is a 224 operating at short wave signal frequency as a first detector and the other tube is a 227 oscillator tuned to 550 kc higher than the desired short wave signal frequency. The resultant beat of 550 kc is fed into the antenna post of the broadcast part of the complete receiver chassis, which operates as an 550 kc intermediate frequency amplifier during short wave reception. The dial of the broadcast receiver must be set to 550 kc during short wave reception.

To balance: Set band selector switch on position C - set dials on about 10. The front section of the two gang condenser tunes the detector stage to signal frequency; the back section tunes the oscillator coils to a frequency 550 kc greater than signal frequency. If the small variable condenser, which is paralleled with the detector condenser, will not resonate its circuit within its capacity range, it will be necessary to change the trimmer located on the oscillator section of the main tuning condenser. This may be done by tuning in a signal and rotating the variable trimmer to maximum resonance; if this point is reached with the balancing condenser plates at maximum capacity, it will be necessary to reduce the oscillator trimmer capacity, and if the resonance point is approached with the balancing condenser at minimum capacity, it will be necessary to add capacity to the oscillator trimmer. This should be regulated so the balancing condenser peaks with the plates about half way out, with the short wave tuning dial set at 50.

The approximate setting of the oscillator trimmer may be obtained by turning the adjusting screw down tight and then releasing it two full turns.

Alignment Data.

HOWARD RADIO CO.

MODEL "H"

ADJUSTMENTS The 175 kc. oscillator must be accurately tuned to 175 kc. and only 175 kc. If this precaution is not observed it will be impossible to align the oscillator to the rest of the set and the set will not operate correctly as the oscillator is designed for exact 175 kc. operation.

The second intermediate frequency amplifier transformer shield can is removed and one side of the small variator condenser is disconnected from the primary coil. This coil is connected so that it still is in the plate circuit of the tube but the tuning condenser is not connected in the circuit. Now remove the grid cap from the intermediate amplifier tube and connect a 3 megohm resistor from the control grid to ground. Now connect the output from the 175 kc. oscillator to the grid of the intermediate frequency amplifier tube and tune the secondary for maximum deflection of the output meter. (Low voltage alternating current meter, 0 to 3 volts, connected across the voice coil of speaker). Now remove the shield can and connect the small tuning condenser that was previously removed back across the primary coil. With the 175 kc. oscillator connected the same as before, tune the primary for a maximum deflection of the output meter. (Caution: Do not under any circumstances try to retune the secondary after having tuned the primary. **This is important.**) After having tuned this stage proceed to the next intermediate frequency:

(b) Replace the grid cap on the intermediate frequency amplifier and proceed to the first detector tube. Remove this tube cap and connect the 175 kc. oscillator as before, being sure to connect the 3 megohm resistor from control grid to ground. Now proceed to tune the intermediate frequency transformer by tuning the secondary first for maximum deflection of the output meter and then tuning the primary for maximum deflection. Tuning this transformer must be done very carefully as the selectivity of the whole receiver depends entirely on the tuning of this transformer.

(c) To line up the radio frequency amplifier and detector stages, remove the oscillator tube and the second detector tube. Unsolder the connection on the plate terminal of first detector tube socket and solder a wire from this terminal to the plate terminal of the second detector tube socket. Now set the Test Oscillator (R. F. Generator) which tunes over the broadcast frequency range to 1400 kcs. Connect the output of this oscillator to the aerial and ground wires of the receiver. Now make sure that when the tuning condensers are all in maximum capacity that the pointer on the escutcheon lines up with the line just beyond the 550 kc. dial mark and then turn the dial until the escutcheon pointer lines up with the 1400 kc. line on the dial. The tuning condenser trimmers should now be adjusted until a maximum deflection is shown by the output meter. Now set the oscillator to 1000 kcs. Turn the dial to 1000 kcs. and then secure maximum deflection on the output meter by moving the serrated plates of the variable condenser in or out as the case may be. Repeat the same procedure at 600 kcs. as was used at 1000 kcs. (Do not touch the trimmer condensers after having once set them at 1400 kcs.). Unsolder the wire connecting the first detector plate terminal to the second detector plate terminal. Resolder the wire that was originally unsoldered from the first detector plate terminal. Now replace the oscillator and second detector tubes.

(d) To line up the oscillator tune the set to 1400 kcs. and adjust the oscillator tuning condenser trimmer (the last hole of the three holes in a line on the top of the tuning condenser housing) as viewed from the front of the set, (see Fig. 1) until a maximum reading is secured on the output meter. Adjust the Test Oscillator to 600 kcs. and tune the receiver to 600 kcs. Now adjust the oscillator series condenser trimmer (the hex. nut in the hole to the left of the oscillator tuning condenser trimmer hole) until a maximum deflection is secured on the output meter. Now reset the Test Oscillator to 1400 kcs. and retune the set to 1400 kcs. and make adjustments if any are necessary on the oscillator tuning condenser trimmer. It is very seldom necessary to make any readjustments at 1400 kcs. after they have once been made.

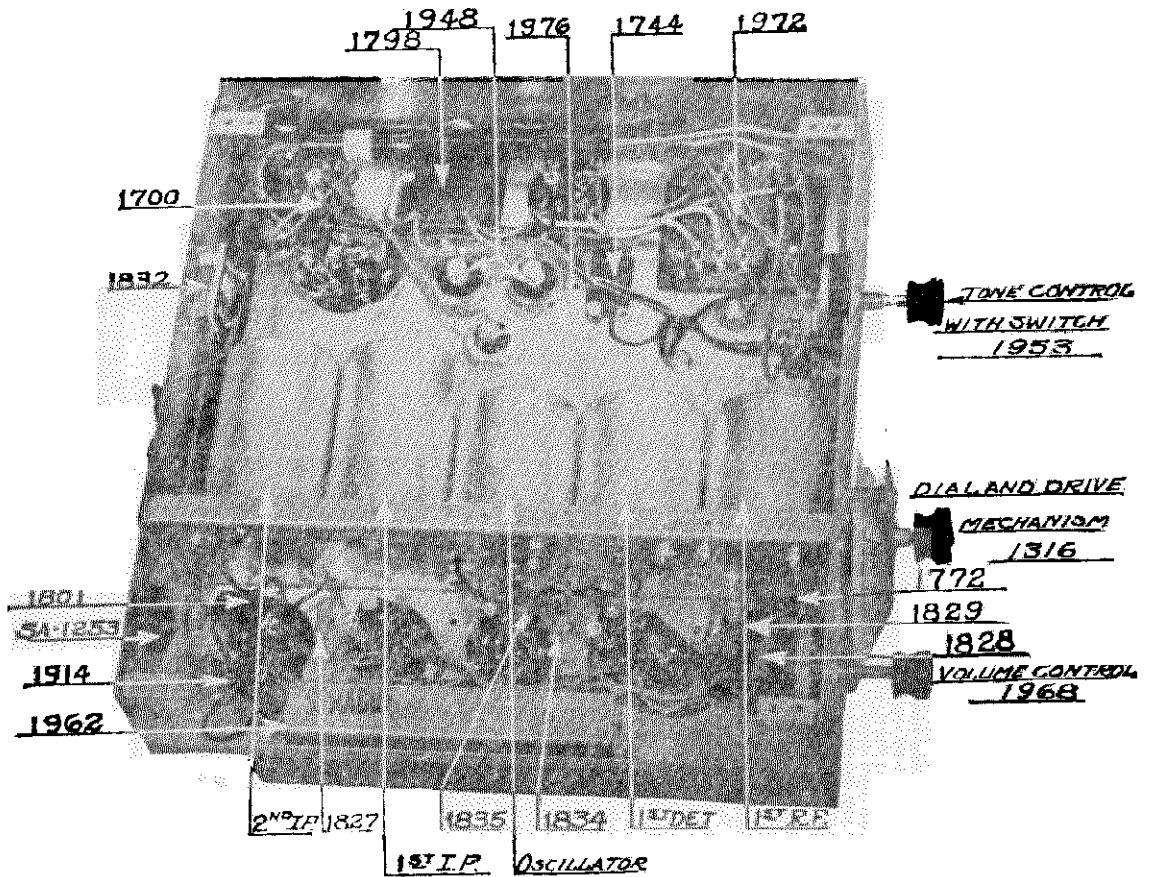

Now tune the Test Oscillator to 1000 kcs. and tune the set to 1000 kcs. Try adjusting the antenna trimmer condenser to determine whether the oscillator aligns at this frequency. If the antenna trimmer must increase capacity to give maximum deflection of output meter the oscillator tuning condenser serrated plates should be moved out. If the antenna trimmer condenser is decreased in capacity the oscillator tuning condenser serrated plates should be bent in towards the stator plates.

The Test Oscillator must again be set to 1400 kcs. and the set retuned to 1400 kcs. to make sure that the antenna trimmer condenser has been correctly reset after the oscillator adjustment has been made at 1000 kcs.

In making tests after having made adjustments according to the foregoing paragraphs, it is necessary to replace the tube and coil can shields before making the tests.

**MODEL 45,60
(AVH)**

Alignment Data

HOWARD RADIO CO.

This cycle goes on until a constant voltage is obtained across the second detector input or in other words until a condition of equilibrium is reached.

The action of the AVC is to maintain a constant voltage across the grid of the second detector regardless of the voltage of the incoming signal. Since this voltage remains constant this means that the audio output also remains constant.

In order to connect the grids of the various tubes to the AVC resistor, it is necessary to insert decoupling resistors P-1897 in each grid lead. These resistors are of such value so that in conjunction with the isolating condenser, they form a resistance capacity filter section so that any modulation from the AVC tube does not reach the grids of the other tubes.

Due to certain detector characteristics it is not advisable to connect the 1st detector tube as much as is necessary with the r.f. and i.f. tubes. The grid return of the 1st detector, therefore, goes to the center tap of the two resistors in the plate circuit of the AVC tube while the grid return of the r.f. and i.f. tubes go directly to the plate of the AVC tube.

4. Volume Level Control.
In the automatic volume control set the receiver is designed so that the maximum audio output is just below the point of overload of the audio power tube. Since this value of output is far more than necessary for normal room volume, it is necessary to introduce some type of volume level control in order that the customer may adjust the output to any desired value. In order to accomplish this a variable resistor is shunted across the secondary of the input transformer to the pentode tubes. By adjusting this control, the volume may be set at any desired level and once adjusted need not be adjusted until it is desired to receive an extremely distant station which has a field strength too weak to operate the automatic volume control.

5. Tone Control.
Since the volume level control on the Model AVH is connected where the tone control is normally connected, it was necessary to re-design the tone control for a new location. This tone control consists of two condensers P-1845 and a variable resistor P-1881. This combination is connected in series across the plates of the two pentodes. The action of this control is the same as that on the Model H in that as low resistance is included between the two condensers, they become more effective in by-passing the higher audio frequencies and at the same time they tune the primary of the output transformer to a lower audio frequency.

6. Visual Tuning Meter.
Since the Automatic Volume Control tends to hold the audio output of the set to a certain definite volume level, it will be at once apparent that the main tuning dial may be rotated quite a distance without any appreciable change in audio volume. This means that the point of resonance is hard to distinguish. In order to tune the receiver to absolute resonance, a visual tuning meter is used. This meter is connected in series with the plate supply voltage of the three controlled tubes. As the bias increases on these tubes as the receiver is tuned to resonance, the plate current decreases. This decrease in plate current is recorded by the meter. A station is in exact resonance when the tubes are drawing their minimum plate current for a given signal strength. At this condition the best tonal qualities are realized from the set. It is important that the service man and dealer both understand this tuning so that the customer may be instructed in the correct manner of tuning his radio set. This broadness of tuning is only apparent and does not effect the selectivity of the receiver. This action is explained fully in the instruction pamphlet with each receiver and should be thoroughly understood so that an explanation can be given the customer.

7. Power Pack.
The power pack is of the conventional type and is similar to the Model H with a few exceptions.

The power transformer has a separate winding for the heater of the AVC tube. This is necessary because if the heater were grounded as the other heaters, it would place 100 volts potential difference between cathode and heater and it is possible that rectification might take place between these two elements which would hinder the action of the AVC tube.

The HV secondary of this power transformer is also changed to give an increased high voltage. This increase is necessary because the AVC tube requires an additional 124 volts for operation.

Since an additional 124 volts is required above the usual 180 volts for plate operation this means that from +B to -B on the voltage divider resistor there is a total of 304 volts. As our power tubes require only 250 volts plate and 16.5 volts bias it is at once apparent that they may be connected between +B and -B with suitable resistors to drop the voltages to the correct operating voltages.

The speaker field is connected the same as in the Model "H" but since the total current of the set now flows through the speaker field the resistance of the field is only 350 ohms instead of 2400 ohms as in the standard Model H.

The filter condensers on the Model AVH are of the dry electrolytic type since these would assist a potential difference between the case and the chassis if the wet electrolytic were used which might shock the user if he happened to touch the case of the condenser and the chassis. These dry electrolytic condensers are housed in a container which is at ground or chassis potential so that this danger is eliminated.

Two pilot lights are used on the Model AVH, one for illuminating the dial and the other for illuminating the meter.

1. Specifications.
The Howard Model AVH receiver is a superheterodyne receiver similar to the Model H receiver with the addition of an Automatic Volume Control.

2. Schematic Circuit.
Draw # 1481 shows a schematic diagram of the Model AVH. Since the Model "H" and Model "AVH" are nearly identical, it will only be necessary to show where in the two differ.

In the radio chassis the following differences are noted:
The first radio frequency transformer SA-1267 is not grounded as in the Model "H". A non-inductive .1 mfd. condenser is connected between the end of this coil and ground. This condenser provides an insulation as far as direct current is concerned for the grid of the radio frequency amplifier tube. From a radio frequency standpoint, this condenser offers a low impedance path to ground for the radio frequency voltage. Since this condenser and the tuning condenser are in series across the tuning coil it is necessary that this condenser be large in order to have small effect on the tuning capacity.

The second radio frequency transformer SA-1268 is constructed in the same manner as the first radio frequency transformer as far as grounding is concerned and needs no further explanation. For actual physical construction refer to section 2 of Model "H" Service Manual.

The first intermediate frequency transformer SA-1278 also has an isolating condenser in the grid circuit. This condenser serves the same purpose as those in the radio frequency transformers.

The initial operating bias for the various tubes is secured by means of individual resistors in each cathode circuit. The plate current flowing through this resistor causes a voltage drop across it which places the cathode positive with respect to ground. Since the grid is effectively at ground potential this is the same as placing a negative voltage on the grid. It is necessary to bias these tubes individually so that there is no common impedance which might give rise to reaction between the tubes. Each resistor is by-passed to form a low impedance path for radio frequency around the resistor.

3. Automatic Volume Control.
The Automatic Volume Control is actuated by means of a type 277 tube and in order to explain its operation it is necessary to explain its action under condition of no signal being received and then its action when a signal is being received.

The tube is connected so that the grid is at absolute -B potential by means of a 2 megohm resistor (P-1889). The cathode of the tube is connected to a point on the voltage divider which is at +24 volts with respect to -B or the grid. There exists then between the cathode and the grid a potential difference of 24 volts with the grid negative by this amount. The plate of this tube is connected to ground by means of two 150,000 ohm resistors (P-1888). Since ground is connected to +124 volts with respect to -B there exists between the cathode and the plate a potential difference of 100 volts. In order to by-pass any radio frequency energy which may appear on the plate, a non-inductive condenser (P-1893) is connected from the plate of the Automatic Volume Control tube to the cathode.

With the condition of no signal there exists a bias of 24 volts and a plate voltage of 100 volts. Under these conditions there is no plate current flowing and the tube is said to be cut-off. Since no plate current is flowing there exists no voltage drop across the plate circuit resistor and, therefore, there is no bias voltage on the grids of the controlled tubes. The only bias on the r.f., 1st det. and i.f. is caused by the respective voltage drops across their cathode resistors. These resistors are designed to give the most sensitive operating point.

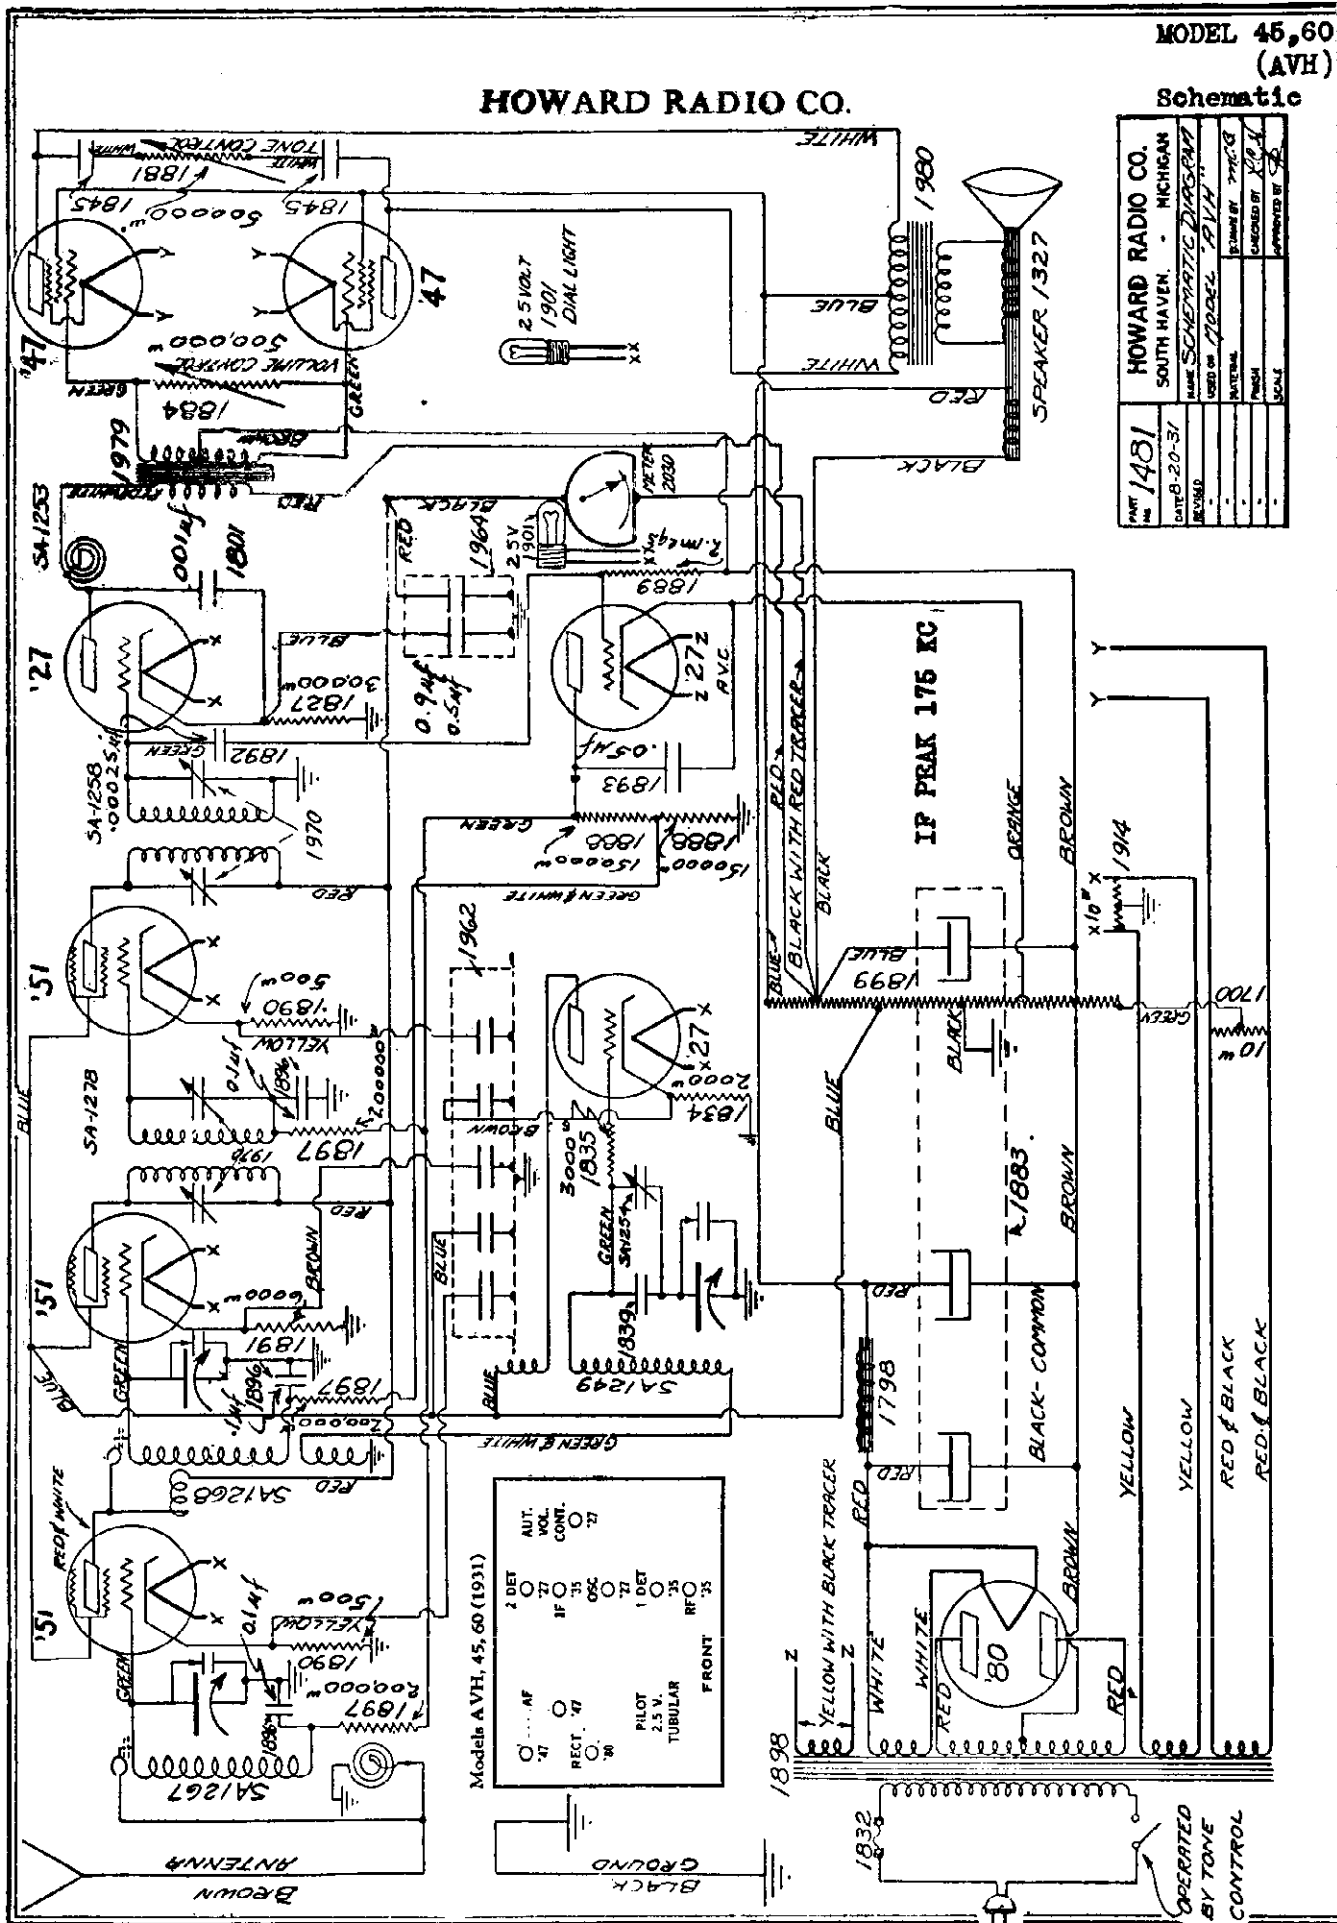

Now let us consider the case of a received signal. The signal passes through the receiver to the second detector grid. Here the AVC (automatic volume control) tube grid and the second detector grid are in parallel. The signal voltage is fed to the grid of the AVC tube by means of a small fixed condenser P-1892. This signal voltage swings back and forth with its center coinciding with the initial bias on the AVC tube. It will be seen that during the positive half at the cycle, the peak voltage of the signal swing subtracts from the original bias voltage. This means that the instantaneous bias on the tube is less than the original bias and the tube begins to draw current in the plate circuit. Since this current flows in the resistors in the plate circuit of the AVC tube, there exists a voltage drop across these resistors. Also the flow of the electrons is from plate to ground so that the plate becomes negative with respect to ground. Now since the original potential of the cathodes of the r.f., 1st det. and i.f. tube is positive with respect to ground, it follows that if the grids of the respective tubes are connected to resistor in the plate circuit of the AVC tube, that any potential existing across this resistor is added to the original bias and makes the grids more negative than the original bias by the amount of the voltage drop across the resistor in the AVC tube plate.

It is at once apparent that the greater the signal voltage appearing at the grid of the AVC tube, the more plate current will flow in plate circuit. An increase in plate current means an increase in bias on the r.f., 1st det. and i.f. tubes. An increased bias on these tubes means less amplification and therefore, less grid swing on the second detector and AVC tube.

OPERATED BY TONE CONTROL

HOWARD RADIO CO

4. Tune primary of intermediate transformer for maximum deflection of output meter. Retune secondary to make sure tuning of primary has not affected the resonant point of secondary.
5. Replace grid cap as originally. Remove grid cap of the 1st detector and connect the 3 megohm resistor from control grid to ground. Connect the output of 175 kc. oscillator to control grid of 1st detector.
6. Tune secondary of 1st intermediate frequency transformer to 175 as shown by maximum deflection of output meter.
7. Now tune primary of this transformer to 175 as indicated by maximum deflection of output meter. Retune secondary to see it has not been affected by primary tuning.
8. Retune second intermediate frequency transformer to make sure it is exactly tuned at 175 kc. as there may be some change in tuning when the 1st detector is connected in the circuit.

No. 1 Radio Frequency Amplifier Alignment.

1. After aligning IF transformers, replace 1st detector grid cap. Unsolder the wire connecting the plate of the 1st detector tube to the IF transformer. Remove oscillator tube and 2nd detector tubes. Connect the plate terminal of 1st detector tube to the plate terminal of the second detector socket.
2. Rotate the condenser in clockwise direction as far as they will go. Make sure that when the rotors of the condenser are all in that the starting mark on the dial aligns with the pointers on the eschachoon. This starting mark is the line just beyond the 550 kc. line on the dial. (See Fig. 1.)
3. Set test oscillator (RF Generator) which tunes over broadcast band to 1400 kc. Connect antenna and ground wires to oscillator. Tune set to 1400, as shown on dial. Adjust trimmer on first and third variable condensers for maximum deflection of output meter.
4. Now tune oscillator 1000 kc. and tune set to 1000 kc. as shown on the dial. Adjust for maximum deflection on output meter by moving serrated plates on rotor of tuning condensers in or out as the case may be. Do not adjust trimmer condensers at this frequency.
5. Repeat process in paragraph 4 at 600 kc.
6. Remove wire soldered from 1st detector plate terminal to second detector plate terminal and resolder wire from intermediate frequency transformer to plate terminal of 1st detector as originally connected.

Oscillator Alignment.

1. Set test oscillator to 1400 kc. Tune set to 1400 kc. and adjust oscillator or second (middle) tuning condenser trimmer for maximum output as shown on the output meter. (Oscillator trimmer condenser second hole of the three in line.)
 2. Set test oscillator to 600 kc. Tune set to 600 kc. Adjust oscillator padding condenser (single hole to left of three holes in line) for maximum deflection of output meter.
 3. Reset test oscillator again to 1400 kc. and retune set to 1400 kc. Readjust oscillator trimmer if necessary. This adjustment is very seldom necessary if the other adjustments are made correctly.
 4. Now tune test oscillator to 1000 kc. and tune set to 1000 kc. Try adjusting antenna trimmer condenser to determine whether the oscillator aligns at this frequency. If the antenna trimmer must increase in capacity to give maximum deflection of output meter the oscillator tuning condenser serrated plates should be moved out. If the antenna trimmer condenser is decreased in capacity the oscillator tuning condenser serrated plates should be bent in towards the stator plates. It must be remembered that a small capacity change in the oscillator circuit means a tremendous frequency change, and this adjustment must be made very carefully.
 5. Now adjust test oscillator to 1400 kc. and retune set at 1400 kc. to make sure that the antenna trimmer condenser has been reset to its original position after Test 4 has been made.
- In making the above tests it is necessary before making each test, to replace all shielding. The foregoing tests are of a delicate nature, and it is essential that each one be made carefully before going to the next test.

Schematic Circuit

The schematic circuit of this receiver is shown in Dwg. No. 1479. The antenna connects to the set by means of the brown flexible lead shown in Fig. 1. The ground also connects to the set by means of a black flexible lead also shown in Fig. 1. (In later models binding posts are provided for antenna and ground.)

Inside the set, the antenna lead goes to a high inductance primary. The other end of this inductance grounds to the metal chassis. From the antenna end of this inductance a single turn of wire is coupled capacitively to the secondary of the radio frequency transformer. This coil is made in this manner so that the amplification will be equal throughout the frequency band. The secondary is tuned by means of a section of a three gang condenser. One end of this secondary connects to the control grid of the radio frequency amplifier tube while the other end is grounded.

The plate circuit of the radio frequency amplifier tube connects to +B voltage through a high impedance choke coil. The plate circuit of the r.f. amplifier is coupled to the secondary circuit by means of a single turn of wire in close physical relation to the grid end of the secondary coil which connects to the grid of the first detector or mixer tube. This single turn gives the necessary capacity coupling to produce uniform amplification over the broadcast frequency spectrum. The secondary coil of this transformer is tuned by a second section of the three gang variable tuning condenser. As with the secondary of the radio frequency amplifier transformer, one end of this coil is connected to the control grid of the first detector tube. The other end of this secondary coil is grounded to the chassis.

In order to introduce the oscillator voltage into the grid circuit of the mixer or first detector tube a small coil is wound in inductive relation to the secondary coil at the grounded end of the secondary. This small coupling coil is insulated from the secondary by means of a pyralin strip.

This small coil is a part of the oscillator inductance. Tuning of the oscillator is accomplished by means of the third section of the three gang variable tuning condenser, which has in series with it a fixed padding capacitor. This padding condenser has across it a small trimmer condenser. This condenser tunes the oscillator to an exact frequency at the low frequency end of the spectrum. One end of the oscillator coil is grounded through the 1st detector coupling coil while the other end connects to the control grid of the oscillator tube by means of a resistor P-1835 (Dwg. 1479). This resistor is used to stabilize the oscillator voltage over the frequency range. The plate circuit of the oscillator contains the conventional tickler coil, and is connected to the screen grid voltage tap for its plate voltage. The oscillator is of the biased type having a bias resistor connected from the cathode to ground. This resistor is by-passed by a section of the by-pass condenser block.

Line voltage, 115 volts. Volume Control, Full On.

(1) Alignment

IMPORTANT: The 175 kc. oscillator must be accurately tuned to 175 kc. If this precaution is not observed it will be impossible to align the oscillator to the rest of the set and the set will not operate correctly as the oscillator is designed for exact 175 kc. operation.

This set is designed slightly different from the Model H superheterodyne in that the second intermediate frequency transformer is not overcoupled.

The following alignment procedure should be followed:

1. Remove grid cap from intermediate frequency amplifier tube and connect the control grid of this tube to a 2 or 3 megohm resistor. Connect other end of this resistor to ground.
2. Connect output of 175 kc. oscillator to control grid of this tube.
3. Tune secondary of intermediate transformer for maximum deflection of output meter. (Low voltage alternating current meter, 0.3 volts connected across voice coil of speaker.)

SA-1281	Radio Frequency Transformer (Antenna)
SA-1282	Radio Frequency Transformer (Interstage)

R.F. Amplifiers:

The secondary of the first radio frequency transformer is connected between the grid of the 1st r.f. amplifier tube and ground. This secondary is tuned by means of one section of a three-gang variable condenser.

The cathode of this tube connects directly to the volume control. The volume control will be discussed under a separate section.

The screen grids of the radio frequency amplifier tubes connect together and then to a point on the voltage divider resistor which applies the correct operating potential on the screens. In order to prevent common coupling impedance these screens are by-passed to ground by means of a condenser. This eliminates a possibility of oscillation from this source.

Connected between the source of B voltage and the plate of the first radio frequency amplifier tube is a high inductance choke coil. This coil is located in the top of the second radio frequency transformer but in physical relation to the secondary of this transformer so that there is no electromagnetic coupling. Connected to the plate end of this choke is a wire which is in close physical relation to the grid end of the secondary of this transformer. As in the case of the 1st r.f. transformer, this wire gives a small capacity coupling. The combination of the choke and small capacity formed by the single turn of wire gives a frequency characteristic which is substantially flat over the frequency range.

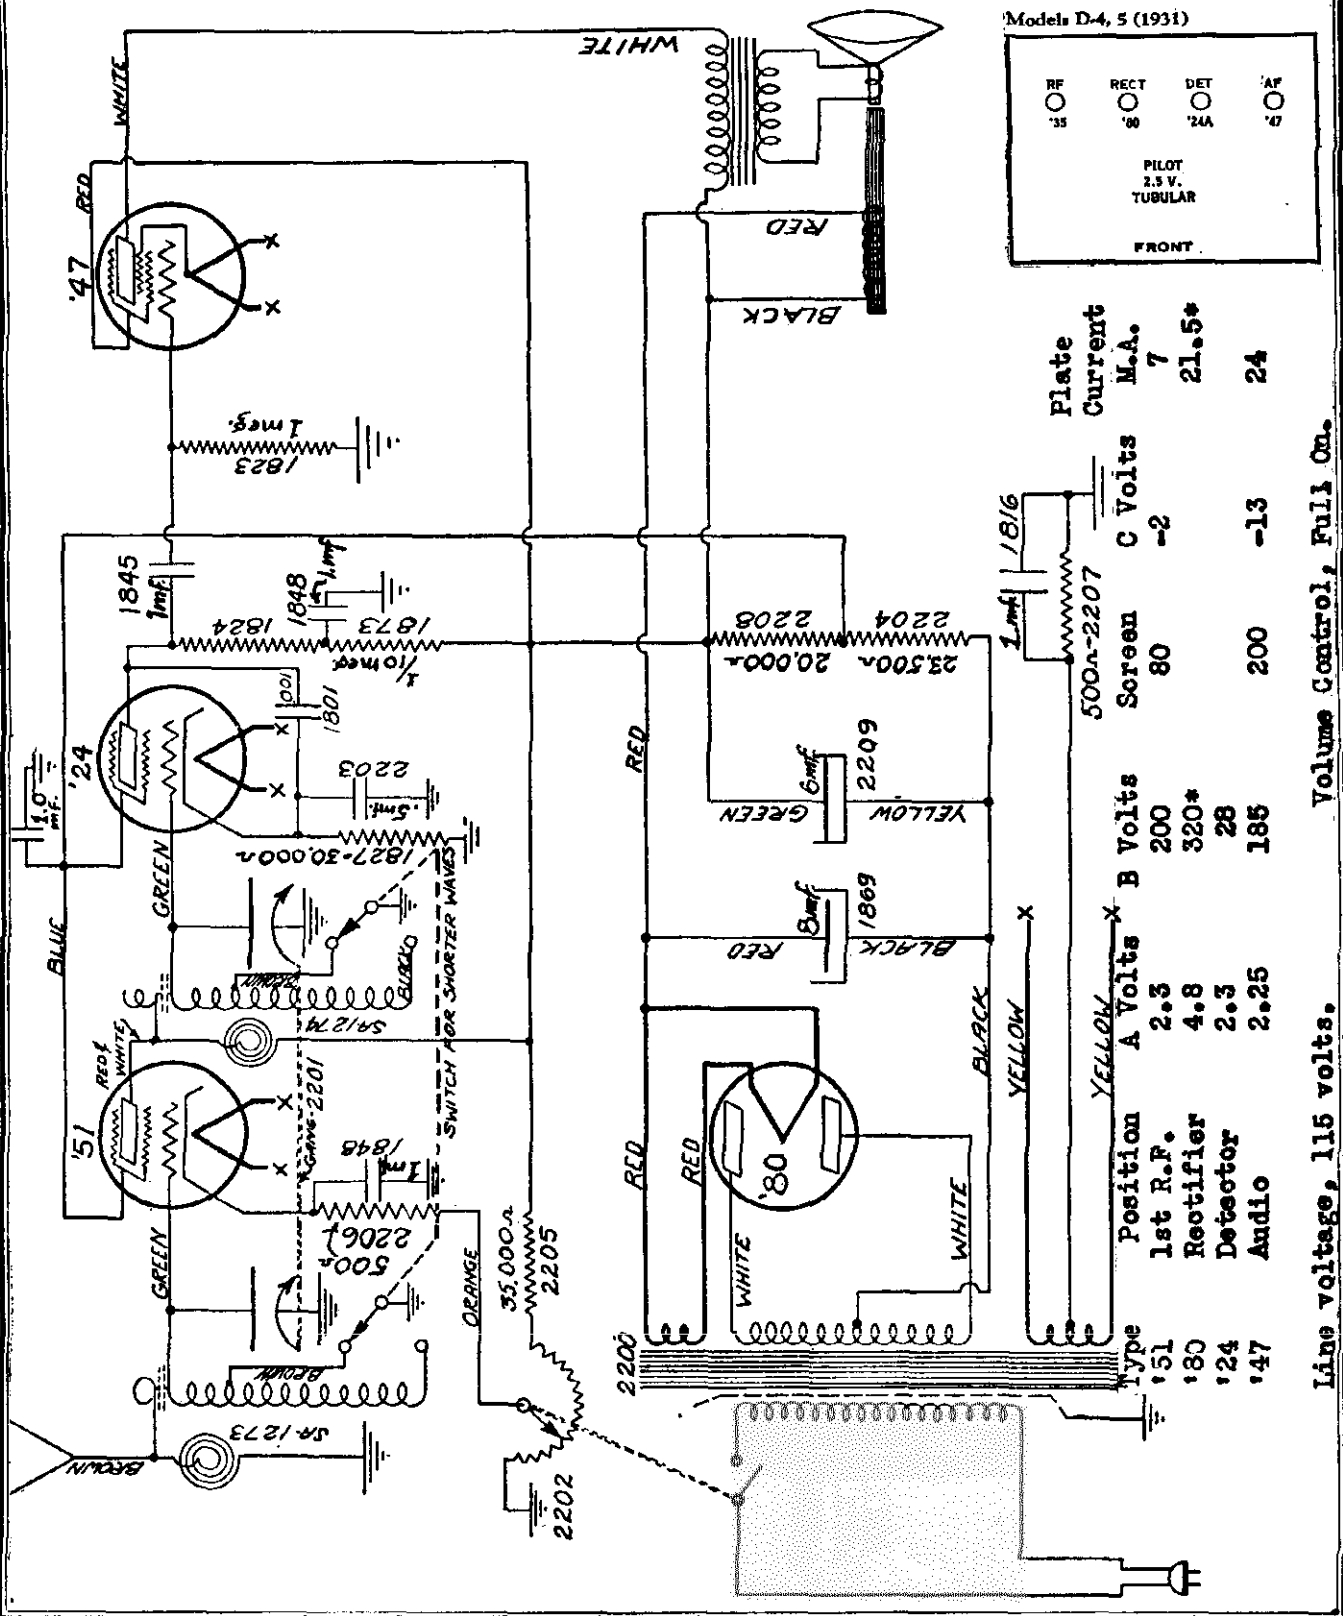

The secondary of the second transformer is similar to the one used in the 1st r.f. transformer and is tuned by means of the second section of the variable tuning condenser. It is connected between grid and ground of the second radio frequency amplifier tube.

The cathode and screen of this tube are connected the same as the first radio frequency amplifier and need no further description.

The third radio frequency transformer is a duplicate of the second, radio frequency transformer and therefore, needs no description. On export models, the ground lead of this transformer is connected to a phonograph jack, and the other terminal of the phonograph jack is connected to ground. In the radio position these jacks are shorted by means of a switch. In the phono position, this switch is opened and the pick-up is plugged into the jack. It is necessary to tune the radio set to some point on the dial where there is no signals from a broadcast station coming in, otherwise the radio signals will feed through and interfere with the phono music.

Direct Current S.G. Chassis
Schematic, Data

COLIN B. KENNEDY CORP.

MODELS 22, 36, 38, 40, DIRECT CURRENT S.G. CHASSIS.

The majority of the parts are interchangeable with those in the corresponding A. C. model.

The standard filter choke is omitted, the power transformer being replaced by the heavy D. C. choke

It will be noted that the position of the pilot lamp differs, in the model 36, from its position in the models, 38, 40 and 22.

The position of the tone control also is different in the model 36 from the models 40 and 22.

All variations in parts are indicated on the accompanying circuit diagram.

The coils for the D. C. models differ slightly from those used in A. C. models, and are obtainable in matched sets of four.

The same dynamic speaker as used on the A. C. models is employed

The filaments of all tubes, a heavy 365 ohm vitreous resistor and the pilot lamp are all in series across the line, following the choke. An 81 ohm resistor "by passes" a portion of the current across the three audio frequency tubes as the type 222 tubes do not draw the full quarter ampere as do the 171-A and 112-A type tubes. As the pilot lamp is also in series with the tubes a bulb of the proper voltage and current draw must be used.

The mechanical layout of the D. C. models corresponds to the equivalent A. C. model in each case except for the few variations noted below.

D. C. Model	Corresponding A. C. Model

MODEL 24
Schematic, Data

COLIN B. KENNEDY CORP.

General Information:
THE KENNEDY Battery Operated Chassis Model 24 is constructed on a base similar to the Kennedy Models 20 and 22 (A.C. and D.C. line models). A great many of the component parts of the battery operated chassis are interchangeable with those of the corresponding A.C. and D.C. line models, 20 and 22.

If set oscillates over entire dial range, it is possible that the detector output filter is defective, and a new one may be tried.

The wires at the tops of the coil shield (no control grids) may have been pulled sufficiently to bond coil legs and perils more than 3/8 inches of wire (from shield to start of clip) to be exposed. Extra length here tends to cause an unstable receiver.

If receiver oscillates at just a small spot or two of dial range, it may frequently be corrected by pushing a piece of solid, bare copper wire between the rubber grommet and coil shield (barely through) of the second R. F. coil shield, and twisting a few turns around the wire leading to the control grid of the 2nd R. F. tube.

Resistors
The resistance values of the various colored resistors employed are:
10,000 ohms.....Grey
50,000 ohms.....Yellow
500,000 ohms.....Brown

Fuses and Ballasts
Under a cover-plate near the battery cable will be found a pilot lamp bulb and a piece of small wire held by two points. This bulb is used as a fuse in the "B" battery circuit and is identical with the pilot lamp—both being Mazda No. 40 (6 volt, 0.15 amp). The fuse lamp does not light up when set is operating, and, it should do so it is an indication of trouble elsewhere in the receiver.

The small wire held by the two points is a fuse and ballast in the storage battery circuit. In addition to its function as a fuse it serves to compensate for variations in the voltage of the storage battery. Extra pieces of this wire are provided with the set, and it is IMPORTANT that no other wire be used. This wire is No. 34 B. & S. gauge Glibby ballast wire. If other wire is used there is danger of injury to the tubes.

In the event it becomes necessary to change a coil it is extremely desirable to change all four coils for a new set of four matched and impregnated coils that are designed to work together.

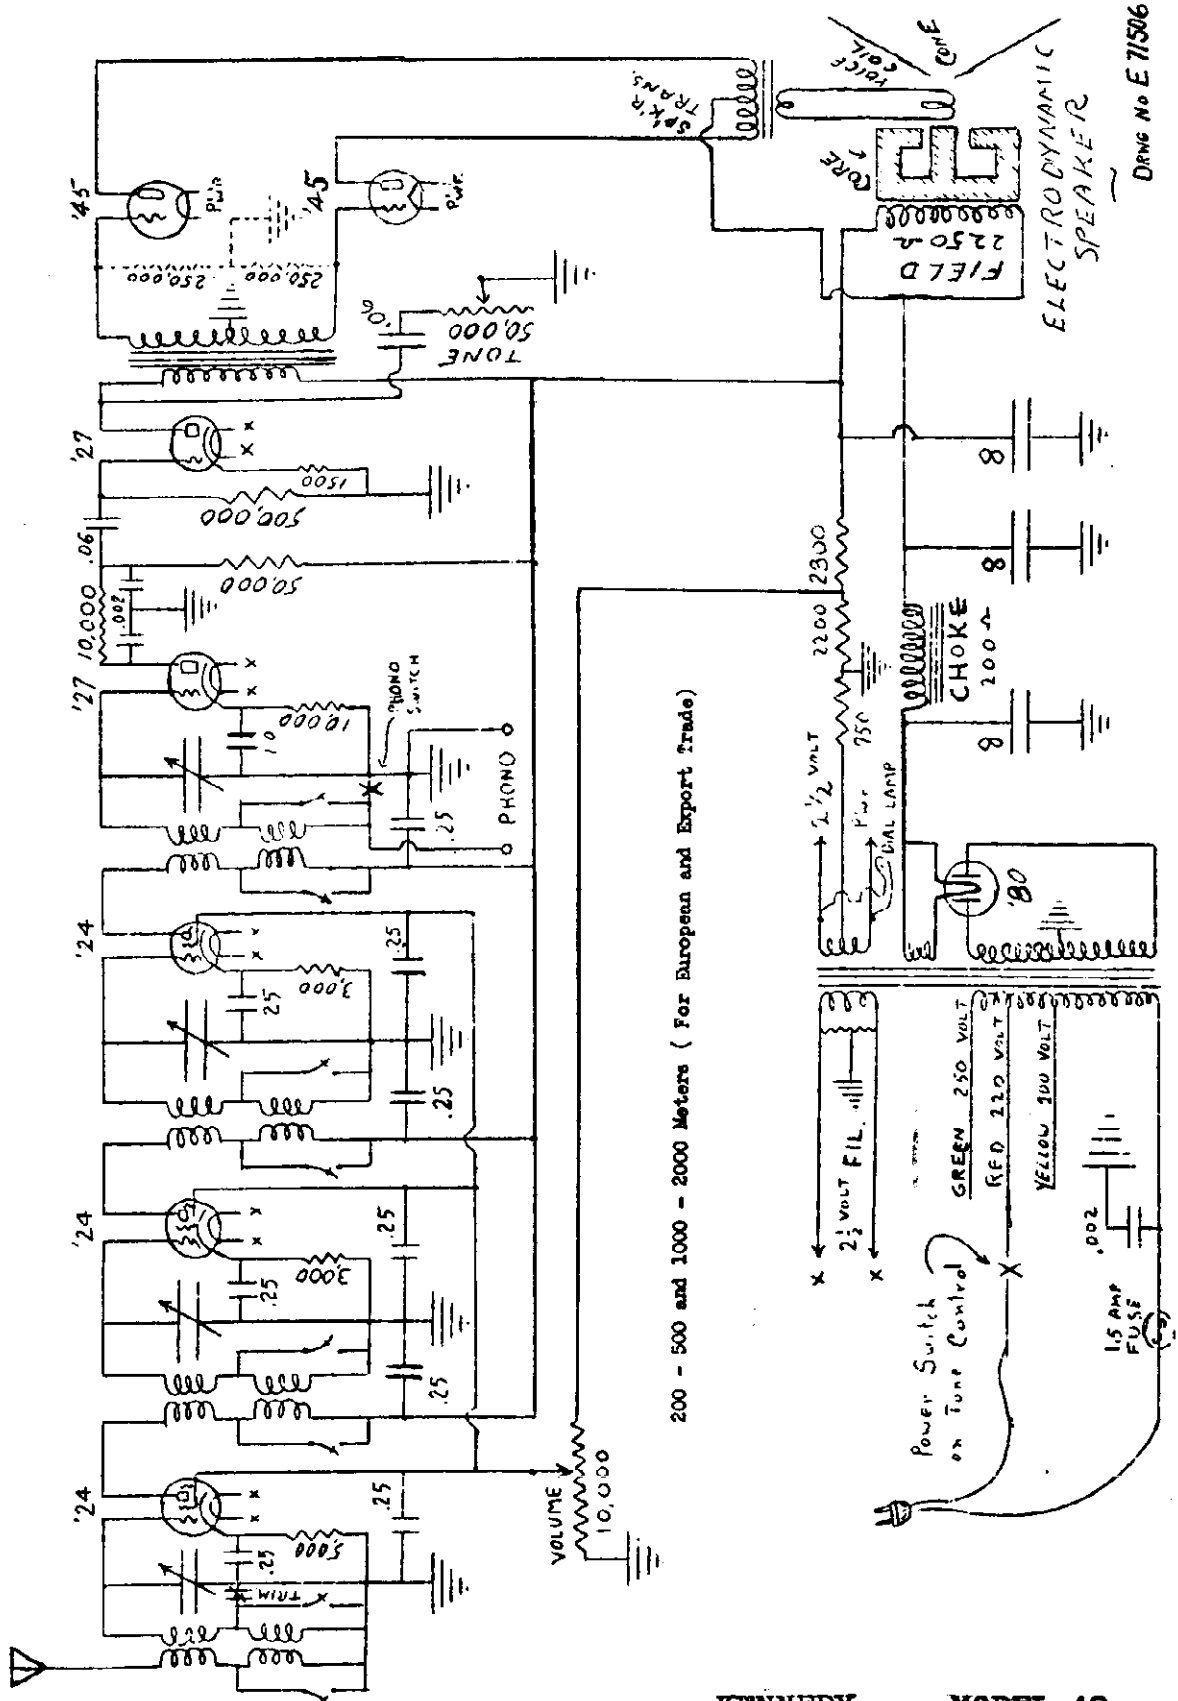

Tests for resonance, or matching of the tuned circuits, are accomplished with an oscillator—connections to the resonant circuits being made from ground to grid terminals of the R. F. sockets for the R. F. coils and from A+ terminal of detector socket to end of grid lead or grid condenser furthest from detector socket grid terminal for the detector coil.

Batteries
The model 24 receiver requires one six volt storage "A" battery and one 135 volt "B" battery (or three 45 volt "B" batteries). No "C" batteries are required as all bias voltages are obtained automatically within the receiver.

The storage battery drain is exceptionally low for this type of receiver, being approximately 1.37 amperes.

Alignment

Alignment of the tuned circuits is made in the conventional manner. An oscillator covering the broadcast band and an output meter or indicator will be found helpful and will speed up the procedure.

The three circuits are first aligned at, or near, the 1,500 K. C. end of the dial. The first condenser section has a "trimmer" condenser which may be adjusted. The other two sections may be adjusted by bending the proper segments of the slotted rotor end plates. A check at four or five positions across the dial range is usually ample.

Tube	Type	Fil.	A.C. Plate	Screen	Bias
1st R.F.	551	2.3	250	175	2.5 to 39

TECHNICAL DATA - MODELS 52 AND 56

ALIGNMENT:-Use an output meter and 175 KC oscillator for aligning the IF transformers. Remove grid clip of first detector tube and fasten a short length of wire to the grid terminal of the tube. Place the oscillator in the vicinity of this wire. Adjust trimmers in tops of IF transformer shields for maximum output meter reading. For adjusting the tuning condenser, an oscillator covering the broadcast band should be used. In this case place the oscillator near the antenna of the receiver. The receiver and oscillator are first tuned to 1500 KC and the condenser trimmers adjusted for maximum output. Do the same thing at 550 KC. It is desirable to move the dial back and forth in making the above adjustments, particularly so when altering any capacities connected with the oscillator circuit.

MICROPHONICS:-This is occasioned by mechanical vibration of the oscillator tuning condenser plates. A particularly microphonic tube may also cause it. See that the tuning condenser is floating on the rubber and that the cabinet is not binding on the dial drive shaft. Oscillation is not paramount in this receiver but an effect similar to this may be encountered at spots on the dial if the IF transformers are not set at their proper setting of 175 KC. Too much RF energy reaching the speaker leads produces a similar effect, overcome by twisting the ground and plate wires together in the speaker cable. This is done before the other two speaker leads are tied along with them.

MODEL 53-SW
 MODEL 54-SW
 Parts List
 Data

COLIN B. KENNEDY CORP.

THE KENNEDY Model 53 short wave unit operates on the superheterodyne principle, and is commonly called a converter or adapter.

When switched to long wave position the power is shut off from the short wave unit. When switched to the short wave position the power is turned on, and after the tubes warm up the unit is ready to operate.

In factory assembled combinations the short wave unit is already properly connected to the broadcast receiver. It is always advisable to check over this wiring, however, and see that all connections are properly and securely made.

The three wires from the rear-center of the unit are to be connected as follows:

BLACK The black wire is to be connected to the ground post of the long wave receiver. The actual ground wire is attached to the GND post of the short wave unit and left there permanently.

WHITE: The white wire is to be connected to the antenna post of the long wave receiver. The actual antenna, or aerial, is attached to the ANT post of the short wave unit and left there permanently.

RED: The red wire is to be attached to a source of "B" voltage—either at the long wave chassis or speaker. Any voltage of from 150 to 250 volts is suitable. It should be obtained from some point in the long wave receiver chassis, speaker or filter system, where it will receive fairly good filtering and be relatively free from A. C. hum.

IMPORTANT. As the output of the short wave unit is tuned to a definite frequency it is necessary to set the dial of the long wave receiver at this frequency, and leave it there while tuning for short wave stations. It is important that the long wave dial be set exactly at the output frequency of the short wave unit.

This point is approximately 1,000 kilocycles.

If for any reason the output frequency of the short wave unit has shifted it may be retuned as follows. Set long wave dial at 1,000 kilocycles or at mark. Tune in short wave signals. Tune output by means of adjustment screw, until signal is loudest. Use a bakelite screw driver. The output adjusting screw is at right hand end of short wave chassis, facing the rear.

In the event a strong local station at or near 1,000 kilocycles interferes with short wave reception, the long wave dial may be moved slightly to right or left of 1,000 kilocycle mark, and the output retuned, as above, to ob-

tain greatest short wave output at this newly selected frequency. Move long wave dial off 1,000 K. C. only a few kilocycles at a time, returning the short wave output each time, until the interference is eliminated.

Should the short wave output adjustment be far out of tune, a simple method of resetting is to feed the output of a laboratory or service man's oscillator (tuned to 1,000 K. C.) into the grid of the 224 tube of the short wave unit (while operating) and with long wave receiver also set at 1,000 K. C. (previously set by means of same oscillator, for accuracy). The short wave output adjustment screw may now be turned until maximum oscillator signal is heard, or an output meter, on long wave set, indicate maximum.

MODEL 54 "Globe Trotter"
Schematic, Chassis
Data

COLIN B. KENNEDY CORP.

When testing the short wave unit at the factory, it is adjusted for use with an average antenna. Improved results may sometimes be obtained by re-adjusting to the antenna actually used. The procedure for this adjustment is as follows:

Almost exactly in the center of the back of the short wave unit is an adjustment screw which can be operated through a hole provided for it. This screw should be turned with a bakelite screw driver, which most service men carry. A metal screw driver will disturb the adjustment.

Set the switch on the position marked "15-25 meters"—tune in a station (music or code) at about 50 on the right-hand dial. Then adjust the screw described above, until the left-hand dial also reads approximately 50 when properly tuned in. This adjustment then holds for all wave bands.

The BLACK wire is connected to the "ground" binding post of the long wave set. The RED wire is connected to the negative side of the speaker field coil (dynamic speaker), to the speaker wire or connection carrying a filtered "B" voltage supply, or, inside the chassis, to the positive end of the voltage divider resistor.

If difficulty is had in getting the unit to operate when initially hooked up, and the "B" source is suspected, 90 to 135 volts of "B" batteries may temporarily be tried. The red wire goes to the "B" +, the black wire to the long wave receiver ground post as before, and the "B" - to the same ground post.

Any source of "B" voltage from 150 to 250-volts is suitable. It should be obtained from some point in the long wave receiver speaker or filter system, where it will receive fairly good filtering and be relatively free from hum. A lower voltage, well filtered, is more to be desired than a higher voltage with a large proportion of A.C. modulation.

Obtaining this plate supply is very simple on many receivers, such as the Kennedy models 210, 310, 220, 320, 1030, 632, 426, 526, 726, and 826. In these cases the B supply may be taken from the tip-jack terminating the black speaker wire. In Kennedy models 42, 50 and 52 it may be obtained at the speaker terminal panel from the side of the field winding which is common with the speaker transformer primary.

The output of the short wave unit is tuned. It is set, at the factory, to tune to approximately 1525 kilocycles. Naturally, the long wave receiver dial must be set at this point for short wave reception, and left there.

In the event the long wave receiver will not tune past 1500 kilocycles, or a strong local broadcast station interferes at that point, the output frequency tuning may be altered slightly to avoid the difficulty. An adjusting screw for this tuning may be reached through a hole in the rear of the chassis. It is located near the impedance adjusting wire and binding posts, and is to be adjusted with a bakelite screw driver, as a metal tool will upset the adjustment.

It will be noted, facing the rear of the chassis, that on the left hand side a wire has been brought out which may be connected to either one of two small binding posts near the end of the base. The purpose of this is to adjust the output impedance of the unit to that of the antenna input circuit of the receiver it is to be used with. The Kennedy models named above have high impedance antenna circuits and therefore require this wire to be on the upper binding post. In doubtful cases this wire may be tried first on one and then on the other, with unit operating, and permanently left where best results are obtained. These connections are indicated on the accompanying illustration.

COLIN B. KENNEDY CORP.

MODEL 54-A
Schematic, Chassis
Data

THE KENNEDY Model 54-A short wave unit operates on the superheterodyne principle, and is commonly called a converter or adapter.

A four-position rotary cam switch changes all connections to any one of three short wave band circuits or to long wave position. This switch makes the proper power and antenna connections, turning off the short wave unit and connecting the antenna directly to the broadcast receiver when in the long wave position. When switched to any one of the short wave bands, the tubes of the short wave unit are supplied with power, and antenna and output connections are made. The short wave unit is, naturally, not used for long wave broadcast reception.

In factory assembled combinations the short wave unit is already properly connected to the broadcast receiver. It is always advisable to check over this wiring, however, and see that all connections are properly and securely made.

The two wires from the left side (facing rear) are to be connected as follows:

BLACK: The black wire is to be connected to the ground post of the long wave receiver. The actual ground wire attached to the GND post of the short wave unit and left there permanently.

RED: The red wire is to be attached to a source of "B" voltage—either at the long wave chassis or speaker. Any voltage of from 150 to 250 volts is suitable. It should be obtained from some point in the long wave receiver chassis, speaker or filter system, where it will receive fairly good filtering and be relatively free from A. C. hum.

A wire, as short as practical, must be connected from the binding post at left-center (facing rear) of unit to the antenna post of the broadcast chassis. The actual antenna, or aerial, is attached to the ANT post of the short wave unit and left there permanently.

MODEL 62
Chassis
Alignment Data

COLIN B. KENNEDY CORP.

Alignment

Before aligning or testing alignment of tuned circuits, it is desirable to "short out" the automatic volume control action. This is done by grounding the grid return wire of the first three tubes at some point between the 10,000 ohm and 100,000 ohm grid return filter resistors. It will be noted that the low ends of the detector coil and 1st I.F. coil secondaries are connected to this wire. The antenna coil is also connected, but through a 10,000 ohm filtering resistor.

In aligning, it is first desirable to see that the intermediate frequency transformers are properly set. This is most readily accomplished by using an output meter and an accurate source of 175 kilocycle radio frequency, such as an oscillator. The accuracy of this oscillator may be checked by tuning a radio set to a station on 700 kilocycles and placing the oscillator near the antenna. A harmonic of the 175 kilocycle oscillator will "zero beat" with the station if the oscillator is correct. Other "harmonic" points may also be tried.

Remove the grid clip from the top of the first detector tube and fasten a short length of wire to the grid terminal of this tube. Lay this wire sufficiently near the 175 K. C. oscillator to note the energy from it in the output meter. With the oscillator set on exactly 175 K. C., adjust the trimmers in the tops of the I.F. transformer shields for maximum reading of the output meter. If the meter tends to read "off scale," move oscillator farther from set and wire, thereby reducing input energy. If these I.F. transformers are badly out of alignment, it may be necessary to place the "pick up" wire on the grid of the 1st I.F. tube and adjust the second transformer alone, at first, then moving wire to detector grid and proceed as above. It will be noted that the 2nd and 3rd I.F. transformers have but one adjustment, while the first has two.

The tuning condenser may be adjusted for alignment or "tracking" of the tuned circuits by a similar method

except that an oscillator covering the universal band should be used. The output meter is used as before. The energy from the oscillator, in this case, is coupled weakly into the antenna circuit—a simple means being to place the oscillator near the antenna wire.

The receiver and oscillator are first tuned to approximately 1,500 kilocycles, and by watching the output indicator, the three condenser trimmers (reached through three holes in top-right of condenser shield, or, in some cases, through removable plate) are adjusted for maximum output. These three trimmers must then be left untouched for all further aligning.

The next step is to tune both receiver and oscillator to some point near 570 kilocycles. Here, the alignment is made by adjusting the "padding" condenser (through hole in rear of condenser shield) for maximum response. If necessary to adjust the two R.F. condenser sections, it may be accomplished by bending the condenser end plates. If found necessary to align at other than the ends of the "band," it may be done by bending the slotted end plate of the condenser rotors. Alignment of the two ends of the scale is usually quite sufficient.

IMPORTANT: It is desirable to move the dial back and forth across the signal while making the above alignments. This is particularly necessary when altering any capacities connected with the oscillator circuit. An insulated or bakelite screw driver (containing little, if any, metal) is advised for use in adjusting "trimmer" or "padding" condensers.

Circuit correction. The bias for the oscillator tube, on later models, will be found to be obtained from the 1st detector cathode resistor instead of the 1,500 ohm self bias resistor as indicated. In this case, the 1st detector bias resistor has been changed from 3,000 ohms, as shown, to 1,000 ohms. The self bias resistor of the 2nd I.F. tube will be found changed to 3,000 ohms.

The automatic volume control functions with the diode second detector. The rectified radio frequency flows from the grid and plate (which are joined) to cathode and ground. It returns through the manual volume control and the two 100,000 ohm resistors to the secondary of the last I.F. transformer, and back to the plate and grid, completing the rectifying circuit. No current flows in this circuit until a carrier wave is tuned in. With no current flowing, the bias for the R.F. and 1st I.F. tubes is obtained in the 300 ohm resistor in series with their two cathodes. The biases of the 1st detector and 2nd I.F. tubes are obtained by individual cathode resistors. When current flows in the diode circuit, points along the resistance path from volume control ground to secondary coil are successively more and more negative with respect to ground due to the drop in these resistors. They are naturally more negative when more current flows in this circuit. Advantage is taken of this to provide almost perfect automatic bias control for the first three tubes by returning the grid circuits of these tubes to a determined point on these resistors. Thus, the negative voltage developed by the diode circuit is added to the fixed bias already provided for these tubes. Stronger signals increase this added bias; weaker signals reduce the added bias; and the result in the over-all response is uniformity of volume level. As the volume control is rotated toward minimum or "OFF," more resistance is added to the automatic circuit, increasing its action, and at the same time operates in the audio system by tending to short out the signal to the first audio tube grid.

In all other respects, the circuit is entirely conventional, and may be tested in the regular ways with standard equipment.

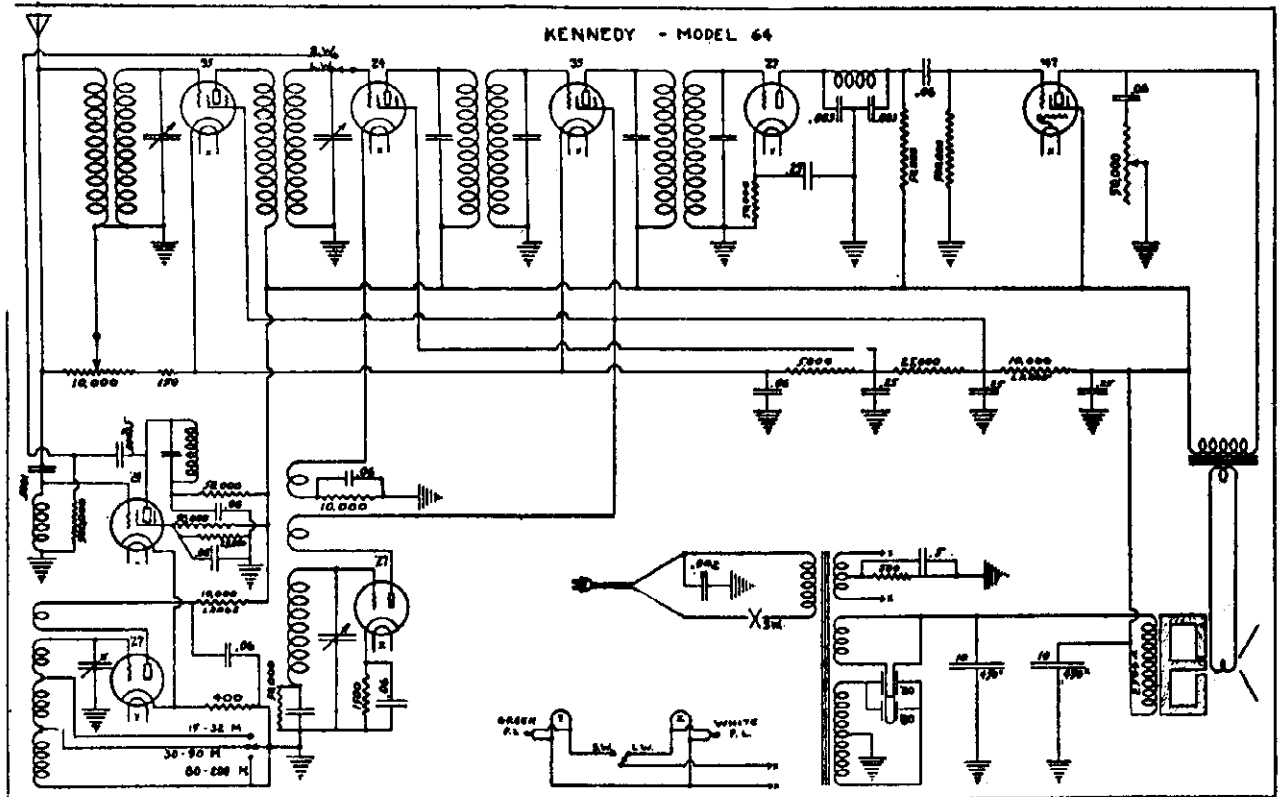

Continuity of circuit and coils may be tested with a battery, meter and pair of test leads. If necessary to replace a coil, it is advisable to replace the entire set of three with a new correctly matched set.

COLIN B. KENNEDY CORP.

MODEL 64
Schematic

Kennedy 10 Tube Long and Short Wave Receiver

CHASSIS MODEL 64

The tubes employed are as follows, and are operated at normal voltages and biases:

Short Wave mixer	224	Long Wave Oscillator ...	227
Short Wave Oscillator	227	Intermediate frequency ..	235
Radio frequency	235	2nd Detector	227
Long Wave mixer	224	Output	247
Rectifier	280's		

For short wave reception the long wave mixer becomes an I.F. amplifier, while the long wave oscillator filament goes out. For long wave reception, the short wave oscillator filament goes out. These circuits are indicated above. The intermediate frequency used throughout is 175 K.C.

In aligning, it is first desirable to see that the intermediate frequency transformers are properly set. This is most readily accomplished by using an output meter and an accurate source of 175 kilocycle radio frequency, such as an oscillator. The accuracy of this oscillator may be checked by tuning a radio set to a station on 700 kilocycles and placing the oscillator near the antenna. A harmonic of the 175 kilocycle oscillator will "zero beat" with the

MODEL 64
Alignment
Socket

COLIN B. KENNEDY CORP.

station if the oscillator is correct. Other "harmonic" points may also be tried. With the receiver switched to short wave position, remove the grid clip from the top of the S.W. mixer tube and fasten a short length of wire to the grid terminal of this tube. Lay this wire sufficiently near the 175 K.C. oscillator to note the energy from it in the output meter. With the oscillator set on exactly 175 K.C., adjust the trimmers in the tops of the I.F. transformer shields for maximum reading of the output meter. If the meter tends to read "off scale," move oscillator farther from set and wire, thereby reducing input energy. If these I.F. transformers are badly out of alignment, it may be necessary to place the "pick up" wire on the grid of the long wave mixer and adjust the last two transformers alone, at first, then moving wire back to S.W. mixer and proceed as before. It will be noted that the first I.F. transformer has but one adjustment.

The tuning condenser may be adjusted for alignment or "tracking" of the tuned circuits by a similar method except that an oscillator covering the broadcast band should be used. The output meter is used as before. The energy from the oscillator, in this case, is coupled weakly into the antenna circuit - a simple means being to place the oscillator near the antenna wire. The receiver and oscillator are first tuned to approximately 1,500 kilocycles, and by watching the output indicator, the three condenser trimmers, reached through the removable plate, are adjusted for maximum output. These three trimmers must then be left untouched for all further aligning. The next step is to tune both receiver and oscillator to some point near 550 kilocycles. Here, the alignment is made by adjusting the "padding" condenser for maximum response. It may be reached through hole in rear center of chassis base.

If necessary to adjust the two R.F. condenser sections, it may be accomplished by bending the condenser end plates. If found necessary to align at other than the ends of the "band", it may be done by bending the slotted end plate of the condenser rotors. Alignment of the two ends of the scale is usually quite sufficient.

IMPORTANT: It is desirable to move the dial back and forth across the signal while making the above alignments. This is particularly necessary when altering any capacities connected with the oscillator circuit.

KOLSTER RADIO, INC.

MODEL K-45

Voltage, Alignment Data, Power Transformer Assembly

It is sometimes noticeable that the Condenser Gang does not respond rapidly enough when a selector button is pressed. This is caused by a slow motor and the brake adjustment should be loosened. The method of adjusting the friction brake is as follows: (1) Unloosen the machine screw holding the slotted brake shoe to the motor. (2) Adjust the friction of the brake shoe by varying the pressure applied to the fibre washer fastened to the motor armature. (3) The brake is adjusted properly when the maximum speed is obtained without the condenser gang carrying by the station corresponding to the selector button pressed. (4) When the proper adjustment has been made, securely tighten the brake locking screw. Ordinarily, no adjustment need be made of this device, as it is properly set in manufacture or if proper line voltage is used.

The motor clutch device is for the purpose of mechanically disengaging the drive motor armature from the tuning condenser simultaneously with the opening of the motor circuit. This electrically-operated device is necessary so as to eliminate the possibility of the inertia of the motor armature, when the motor circuit is open, from turning the tuning condenser past the pre-determined setting of the selector brush.

Make certain that the position of the line voltage switches in both the power pack and relay unit are set to correspond with the existing AC line voltage.

If it is desired, the remote cable may be disconnected from the receiver by removing the nuts holding the terminal card to the motor unit and relay box. This will in no way interfere with the operation of the set at the local position.

Four adjustable trimmer condensers are provided on top of the main gang condenser to compensate for small capacitive variations in the tuning circuits. This condition is made noticeable by the receiver becoming insensitive.

If it appears a certainty that the tuning circuits are not balanced, a simple method for readjusting is as follows:

- 1—Tune in a signal, preferably at the low end of the dial, and adjust the volume control for a moderate signal intensity.
- 2—Adjust with a short bakelite screwdriver the four compensating condensers successively, from the detector to the first RF stage, for the greatest signal intensity.
- 3—The various adjustments can now be checked at medium and high points on the dial, making slight variations if it is found necessary.

Bending the end plates of the variable tuning condensers in order to align the gang should only be resorted to if the trimmers are not sufficiently effective. This method will only be necessary in extreme cases where the condenser gang has been subjected to abuse or severe handling.

Should it ever be necessary to replace the cone assembly the proper procedure is as follows:

- 1—Place the speaker flat on the felt ring.
- 2—Unsolder the two leads coming from the output transformer to the voice coil.
- 3—Remove the four long bolts from the back of the field coil housing.
- 4—Lift the field coil and assembly straight upwards and away from the cone assembly to which remains the end plate.

To recenter a voice coil the above procedure is followed, and with the cone assembly remaining flat on the felt ring there will be found the heads of three small machine screws close to the opening in the end plate for the voice coil. Loosen these screws and shift the cone assembly until the voice coil is concentric with the hole in the end plate. Retighten the screws just loosened and reassemble the unit in the reverse manner in which it was disassembled.

Care must be taken against damaging the voice coil against the pole piece and also the four long assembly bolts must be drawn up as tightly as possible.

- Resistor, vitreous, tapped (R6-R7-R8-R9)

Model K 80-82 sets as originally manufactured employed 15,000 ohm volume control unit, (Stamped No. 62018). To improve volume control action, this unit has been replaced with 15,000 ohm potentiometer, (Stamped No. 62025).

In addition to replacing the volume control unit as just described, a 1,000 ohm fixed resistor, Part No. 6569-15, is installed in the Cathode circuit of the automatic volume control tube. This should be connected between the end of the volume control unit (R-10) and the 20,000 ohm resistor (R-9).

Condenser Adjustments, Data

Models K-60—K-62—K-70—K-72—K-80—K-82—K-90—K-92

**R.F. TUNING AND OSCILLATOR TRIMMING CONDENSER
ADJUSTMENTS**

Located on the front of the gang condenser are three trimmer condensers (TC-1-2-3) which are provided for aligning the R.F. circuits. The 600 K.C. trimmer condenser (OC-1) for the OSCILLATOR will be found on the right hand top of the chassis base directly in front of the '80 socket and opposite the coil shield. Poor tone, lack of sensitivity and selectivity, or complete inoperation of the receiver may be caused by these condensers being out of adjustment.

(a) Place the oscillator in operation at exactly 1400 K.C. and couple it to the antenna. Connect the output device in accordance with the type used. Tune in the oscillator signal and adjust the coupling between the oscillator and the antenna lead of the set, or increase the volume control setting until a deflection is obtained in the output meter.

(b) With an insulated screw driver adjust each of the trimmer condensers mounted on the gang condenser frame until a maximum deflection is obtained in the output meter. If the pointer goes off scale reduce the coupling or the volume control.

(c) Set the oscillator now at 600 K.C. Tune in this signal with the receiver and adjust coupling or volume control for a deflection in the output meter. Now adjust the oscillator 600 K.C. trimmer condenser (OC-1) until a maximum deflection is obtained. In making this adjustment it is advisable to rock the tuning condenser back and forth a few degrees each side of the normal position.

(d) Change the setting of the oscillator back to 1400 K.C. and readjust the three trimmer condensers.

If attention is given to the adjustments the R.F. and oscillator circuits will be properly aligned and satisfactory results should be obtained. If not the next step is to adjust the I.F. circuits.

I.F. CIRCUIT ADJUSTMENTS

A single intermediate frequency stage with two transformers is used in band-pass arrangement. Each transformer has both the primary and secondary windings tuned accurately for 175 K.C.

To adjust these circuits proceed as follows:

(a) Set the previously mentioned oscillator at 175 K.C.

(b) Connect the output device.

(c) Remove the oscillator tube, which is the type '27 adjacent to the type '80, and make a good ground connection to the chassis.

(d) Connect the output of the oscillator to the Control Grid cap of the first detector, which is the type '24 tube.

(e) Adjust the oscillator output or the receivers volume control until a deflection is obtained in the output device.

(f) Place the chassis on end and the adjusting screws for the I.F. transformer condensers (IC-1-2-3-4) will be found through holes in the under side of the base after the bottom shield has been removed.

(g) Adjust the secondary and primary of the second and first I.F. transformers in the order just mentioned until a maximum deflection is obtained in the output meter. Make these adjustments the second time to insure proper aligning. It is now advisable to recheck the R.F. and oscillator condensers again.

LINE VOLTAGE VARIATIONS Models K-60—K-62 and Models K-70, K-72

These models were tested on 115 volts, and are therefore suitable for operation on line voltages ranging from 110 to 120 volts. Should lower line voltages be encountered it will be necessary to remove the chassis from the cabinet and unsolder the BLUE lead, which comes from the under side of the power transformer and is connected to one side of the line switch mounted on the rear of the volume control. In its place solder the GREEN lead, taping the end of the Blue lead just removed so that it will not short against other leads in the chassis. In locations where the line voltages exceed 120 volts, a suitable resistor will be necessary to reduce the voltage applied to the correct value.

CAUTION

**NEVER TURN ON THE POWER TO THE SET WHEN THE
SPEAKER IS DISCONNECTED**

Troubadou

DOTTED LINES SHOWN ARE IN SPEAKER

The model 32 W chassis used in the Troubadou and Lafayette is similar in many respects to the Commander, Cavalier, Coronado and Cortez. The special differential features of this chassis are the band pass filter and the radio frequency transformers.

A band pass filter is used in the antenna input stage, and consists of two separate tuned circuits which are inductively coupled. The advantages of this filter are an increase in selectivity; elimination of cross talk and improved tone. Incorporated in the filter is a special coil and condenser, which is inductively coupled to the grid coil of the first tube, tending to give this stage a constant gain over the entire frequency band.

Another feature of this set is the tuned radio frequency coils which have two separate primary windings, so connected as to give equal gain throughout the broadcast band. A screen grid power detector is used, giving the advantages of sensitivity with very good overload characteristics. The over-all fidelity response characteristics are especially good, due to the resistance coupling used in the first stage of audio, and the 245 tubes in push pull in the last stage. Sensitivity in this chassis averages 4 Microvolts per meter.

R.F. Coils

The antenna input transformer is of the high impedance type, and is both inductively and capacitively coupled. The primary winding is on a small bobbin inside the coil form wound concentric with the secondary, allowing inductive coupling. The capacity coupling is obtained by an extra turn of wire connected to the primary and wound on the coil alongside one end of the secondary winding. This antenna coil is coupled to the grid coil of the first tube through three turns of wire wound on the low potential end of the grid coil. Inside of the grid coil is a small bobbin coil shunted by a 100 mufd. condenser, and being in inductive relation to the grid coil. This small coil with condenser in shunt is tuned to the lower frequency. The 100 mufd. condenser is a small condenser without any color marking to distinguish it from the 50 M.M.F. condensers with the yellow dot which are used in the other stages of the radio frequency. The primaries of the radio frequency coils proper, are made up of two parts; the inside primary is wound on a bobbin which is inside the coil form, and is shunted with a 50 M.M.F. condenser. The outside primary is wound on the coil form over the secondary winding and is separated by an insulated strip, the two primaries being connected in series. The energy transfer of the inside tuned primary decreases with increase in frequency—the energy trans-

fer of the outside primary increases with increase in frequency resulting in a net gain that is practically uniform over the broadcast band. Any trouble in the R.F. coils of this receiver will be noted by the lack of sensitivity at either the high or low wave part of the dial.

Twenty-Five Cycle Chassis

A twenty-five cycle power transformer and an additional .45 M.F.D. condenser are used in this chassis. In converting a sixty cycle chassis to twenty-five cycle, first remove the .1 M.F.D. condenser across the filter choke and connect it across the .1 M.F.D. screen condenser. This provides additional filtering. Connect the .45 M.F.D. condenser across the filter choke.

IMPORTANT

All chassis below serial number 139149 use volume control P-90966 shown in Figure 1. Chassis above 139149 use volume control P90969 shown in Figure 3. When replacing volume controls use P90969 and volume control connections shown in Fig. 3.

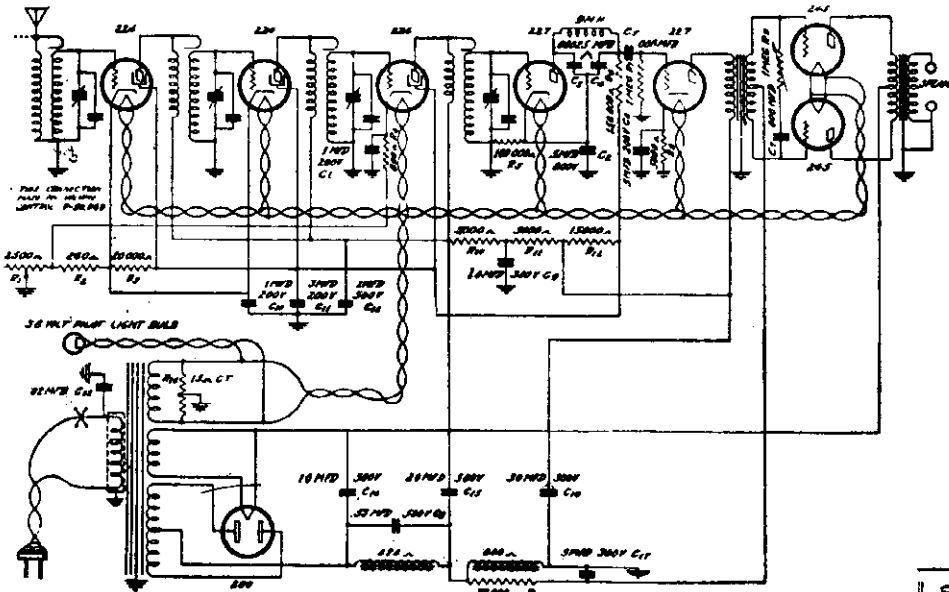

FIG. 3 25-Cycle Chassis

Tube Voltages

All D.C. voltages taken with a 1000 ohm per volt meter on the scale indicated in column headed "Meter Scale." Turn the volume control all the way on and connect the antenna and ground leads together.
The grid, plate, and screen grid voltages are measured to cathode of the heater tubes and to filament of three-element tubes.
The dynamic loud speaker has a field resistance of 600 ohms. The field is used as one of the filter chokes in the power pack.

R.F. Coils

The R.F. Coils on this receiver are both inductively and capacitively coupled in such a way that the R.F. gain is constant throughout the entire broadcast band. Each coil is marked with a streak of paint inside the secondary coil near the lugs, according to the group into which it falls. Four coils of the same color are used in each chassis. When ordering a coil for replacement, therefore, be sure to mention the color of the paint on that coil so that it will be replaced with one of identically the same characteristics. If there is any doubt, return the coil. It is seldom that one of these radio frequency coils needs replacement, but should it be necessary to do so, first unsolder the wires on the coil lugs, then loosen the nuts holding the metal coil can. After the coil can is removed, loosen the two nuts holding the coil form and remove the coil.

NOTE "GRENADEIER" No 62-12
Two entirely different chassis were supplied to the Retail Stores under the name "Grenadier." Each chassis, however, has a different Catalogue number and should be distinguished from this number. The Grenadier No. 62-12 uses the U. S. Radio 8 tube chassis and is exactly the same as our Nos. 1238 and 1838. Therefore, when servicing or ordering repair parts for the Grenadier No. 62-12, use the No. 1238 and 1838 service manual. Grenadier No. 62-14 (Catalogue No. 62-11) is the Wells-Gardner 8 tube chassis which will be described in this service manual.

The voltage readings on this chassis cannot be taken in the conventional way, namely between the tube elements and ground. You will note from diagram Figure No. 1, that the ground connection is taken off the shunt resistor near to the positive end, and the chassis is therefore, approximately 150 Volts positive, with respect to the tube elements. The correct voltage readings may be obtained by taking readings to the cathode of the heater type tubes, and filament of the 247.

TURN THE VOLUME CONTROL ALL THE WAY ON, CONNECT THE ANTENNA AND GROUND LEADS TOGETHER AND TURN THE GANG CONDENSER PLATES ALL THE WAY OUT. CHECK THE LINE VOLTAGE.

MONTGOMERY-WARD & CO.

MODEL 62-11, 62-12, 62-14

62-27

Socket-Data

Figure 2—Top View of Chassis

Oscillator

A 227 tube used in this socket that does not oscillate will completely stop any signals from reaching the intermediate frequency amplifier and the chassis will not operate. There is also a slight variation in the characteristics of tubes, and for this reason it is advisable to try a number of tubes in the oscillator position and to use the one which gives the most satisfactory performance.

The oscillator has an adjustable tracking condenser which is adjusted at 600 kilocycles and remains fixed thereafter.

Automatic Volume Control Tube

The automatic volume control tube is equally as important as the oscillator tube. In this chassis a 224 is used. If the A.V.C. tube's characteristics are not exact, it will cause the chassis to lack sensitivity or spoil the tone quality. The tuning meter will not function properly with a poor A.V.C. tube. If the grid circuit of this tube is open the chassis will lose its sensitivity and in some cases will not pass signals. In each installation, therefore, it is advisable to try a number of 224's in the automatic volume control position and use the tube which gives the most satisfactory performance as to control of volume, operation of tuning meter, and tone quality.

Replacing Rubber Drive

You will note that the Vernier tuning drive on this chassis uses a rubber pinion. Under normal operating conditions this rubber will last for a number of years. Should it become worn it can be readily replaced by loosening the set screw of the brass bushing located next to the rubber pinion and pulling out the station selector shaft. Place a new bushing in position, slip the station selector shaft in place and tighten the set screw.

25 Cycle Chassis No. 62-14X

The 25 cycle receivers use power transformer No. P50540 instead of P50539. Two 8.0 mfd. electrolytic condensers No. P80880 are used instead of No. P80873 and No. P80874. The .25 mfd choke condenser C10 is not used in the 25 cycle chassis.

Resonance Meter

This meter is a small milliammeter in the plate return of the R. F. tube. When the receiver is turned on, and no signal is tuned in, the meter will indicate the total plate current drawn by the R. F. tube. When a signal is tuned in, the meter will indicate less current, and when tuned to resonance, the greatest swing (or least deflection), of the meter hand will be obtained.

The deflection of the meter hand will vary according to the setting of the manual volume control on this chassis.

Method of Aligning

These chassis will only lose their alignment when they have been subject to extremely rough handling or have been used under abnormal conditions, as for instance, a very hot or very humid location. Under any one of these conditions, the alignment may shift slightly and the chassis should be realigned according to the following procedure.

Tune in a local station of approximately 1300 Kilocycles, being very careful to tune this station in at the exact resonance point. This may be easily done by carefully adjusting for maximum deflection of the tuning meter. Then reduce the volume to the desired level. Turn to Figure 2 and note the position of the first radio frequency trimmer adjustment. Slowly turn the trimmer to the right or left until the signal is at maximum intensity. Proceed to adjust the detector trimmer in the same manner. In most instances these two adjustments will align the chassis perfectly. If the receiver still lacks sensitivity after the first RF and detector trimmers have been adjusted, then the oscillator trimmer may be checked by turning the adjusting screw not more than a quarter of a turn to the right or left of its present adjustment. When aligning any of these receivers be sure that the condenser shield is firmly in place and that you are using good tubes in the chassis. This is particularly true in case of the oscillator and automatic volume control tube.

The R. F., 1st detector, oscillator and 1st I. F. tubes have one side of their heater circuit grounded.

The voice coil and speaker frame are grounded to prevent any "feedback" of a 175 K. C. frequency which might enter the speaker.

MODEL 62-11,62-14,62-19,
62-27

Schematic (2nd Type) MONTGOMERY-WARD & CO.
Schematic-Data

The automatic volume control system in this chassis has been changed and therefore some of the parts are not as listed and described in the service manual. The parts which differ are listed below and the revised automatic volume control circuit is shown in the schematic wiring diagram on the opposite side of this sheet. No other changes in the circuit or in the mechanical arrangement of the chassis have been made.

A chassis in which the automatic volume control system has been changed may be identified by a green paint mark on the left rear corner of the chassis near the speaker socket, or by two grid leaks brought out of the top of the 2nd I.F. transformer assembly. This chassis formerly had but one lead brought out of the top of the 2nd I.F. transformer assembly. The resonance meter furnishes a further means of identification as the deflection of the meter hand will not vary when the setting of the manual volume control is changed. This is due to the manual volume control having no effect on the action of the automatic volume control tube. The manual volume control is connected in parallel in the grid circuit of the 2nd detector tube and is used to vary the resistance in that circuit and, in so doing, control the input to that tube.

The following parts are for use only in a chassis having the revised automatic volume control system and are not interchangeable with those listed in the service manual repair parts list.

When ordering parts for replacement, be sure the correct part number is given.

Part No.	Name	Cost Price
P-90988-A	Candohm Resistor	\$0.38
P-90988	500,000-ohm Volume Control.....	.30
P-1446	2nd I.F. Transformer Assembly....	.70
P-70719	Shielded Volume Control Wire Assembly06
P-1445	R.F. Interstage Coil Assembly....	.37

(The 40,000-ohm Resistor, R16, is a part of this assembly. The 500,000-ohm Resistor, R15, is a part of the R.F. Interstage Coil Assembly (Part No. 1397) listed in the service manual.)

MODEL 921, 923, 924, 839
(Radiola 21, 22)
Conversion Data

MONTGOMERY-WARD & CO.

Method of Converting a 6 Volt Receiver for Using the 2 Volt Tubes

ALL of the original Radiola Models 21 (Table Model) and 22 (Console Model) were designed for 6 Volt storage battery operation. It is possible, however, to change the wiring of these sets slightly so that the new 2 Volt dry cell tubes may be used in conjunction with either the Aircell battery or our 2 Volt long life A battery.

Description of the original receiver for storage battery operation is given first. Following this, the method of changing over the set for 2 Volt tubes will be shown. The original color code is shown on the schematic diagram, Figure No. 1. For storage battery operation the cable should be connected to the batteries according to this code.

The following parts are necessary:

One No. 6000 long life A battery designed to last one year at three hours a day. One kit of tubes consisting of 2—No. 232 screen grids; 2—No. 230's; 1—No. 231. One new instruction book. One No. 5512-75 Milliampere pilot light. One pair of green and red resistors. One socket chart label to stick over old RCA labels. The last four items can be ordered on stock order by specifying "one conversion kit for Radiola Set." The A battery and tubes should be ordered on stock order in the usual way. When you receive all of the necessary parts to make the conversion, you will use them in the following manner:

Operation No. 1

First examine Figure No. 2. There are three resistors at the back of the chassis mounted directly underneath the sub-panel. The wires attached to these three resistors must not be removed but the three resistors should be shorted out by soldering short pieces of wire across as shown on the dotted lines in Figure No. 2. On the console models it is not necessary to remove the chassis to do this. Remove the chassis when changing the table model.

Operation No. 2

Insert new low drain pilot light and adjust the position by sliding the pilot light clamp up and down until the figures on the dial can be seen prominently.

NOTE: The insertion of this new pilot light is extremely important—the life of the A battery depends upon it.

Operation No. 3

Remove the Radiola instruction book, red service card and pilot light. Discard them.

Operation No. 4

Remove the battery tag from the cable and destroy it.

Operation No. 5

Connect one end of the green (2.2 Ohms) resistor to the end of the yellow positive A battery lead. This is important.

Operation No. 6

Insert new instruction books and paste new tube chart label over RCA tube position chart, and advertising sticker. This label is designed to cover the tube replacement label and the socket chart. Don't cover up the license notice.

The tube chart indicates the position of the new tubes. 232's—R.F. stages—230's—1st Audio and Detector—231—last audio.

The red resistor is given to the customer in an envelope. It contains a small red label tied at one end and instructing the customer how to use it, which is as follows:

Over a period of time the A battery voltage will drop. Its initial voltage is slightly over 3 Volts. The green re-

sistor drops this 3 Volts down to 2 Volts for the tubes. After the set has been used for a few months the battery voltage will drop to about 2½ Volts, so it is necessary to use a smaller resistor on the battery to give the tubes 2 Volts. When the set begins to lose volume and the tubes go dim, the green resistor should be replaced with the red resistor. After the receiver has been in use a few months more, the battery voltage will drop to about 2 Volts, then the resistor should be removed entirely and the battery used alone until dead.

Note: The new color code and method of connecting the battery cable is shown in Figure No. 3. Use this color code for connecting the batteries after the conversion is made.

Caution: Be sure all battery connections are correct.

Alignment:

In order to align the condensers, it is necessary both in the console and table model, to first remove the chassis from the cabinet. Connect up all batteries and tune in a station at about 1400 Kilocycles. The trimmer condensers will be found mounted on the frame of the variable condenser nearest the front panel. These should be adjusted in turn for maximum volume on a station that does not fade.

Long Distance Switch:

In many localities the local distance switch will not operate satisfactorily on the local side.

In the country it is seldom necessary to use the local switch on the local side, for it is only put on as a safeguard to enable proper control of volume when under the shadow of powerful broadcast stations.

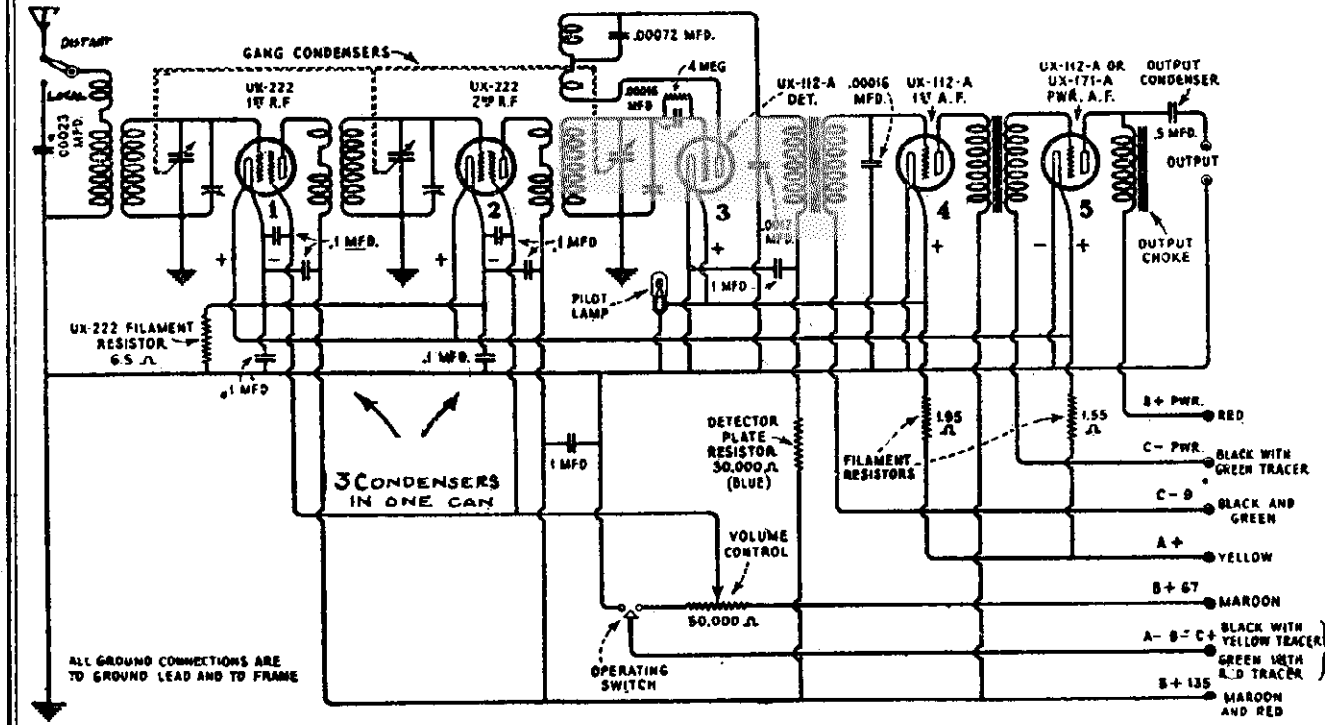

IMPORTANT NOTICE

If the pilot light should burn out and you are unable to obtain another one immediately, remove the celluloid strip from the escutcheon plate by sliding it out of its slot from the rear. This will enable the user to see the figures on the dial until such time as you are able to put the correct pilot light in place. **Never use any pilot light but the No. 5512 we recommend.**

MONTGOMERY-WARD & CO.

MODEL 921, 923, 924, 839
(Radiola 21, 22)
Schematic-Data

General Description

Radiolas 21 and 22 are the tuned RF type, using two stages of radio frequency and one tuned antenna stage. The antenna coil has a high impedance primary and for this reason will give most satisfactory performance on an outside aerial of from forty to seventy-five feet long, including Lead-in. A forty foot aerial should be used in congested localities where there is serious interference. In the event it is impossible to install an aerial and lead-in of from forty to seventy-five feet, a longer aerial may be used and a .0005 or .0001 MFD fixed condenser connected in series with the antenna connection to the set.

Volume Control

The volume control consists of a 50,000 Ohm Potentiometer connected in the B+67 Volt lead and controls the screen voltage to the two RF tubes. The on and off switch is of a special type which automatically breaks the A & B connections when snapped in the off position.

Six Volt Storage Battery Operation

Figure No. 1 gives the completed circuit for operation on 6 Volt A supply. Two type 222 tubes are used as radio frequency amplifiers. A 112A detector, a 112A tube in the first audio stage and a 112A or 171A tube in the second audio stage. The two 222's used in the RF stages receive their filament supply of 3.2 Volts through the 6 1/2 Ohm resistor connected in the A. negative lead. The detector and first audio are operated at 5 Volts through the 1.95 Ohm filament resistor in the positive A lead. The filament of the power stage is supplied through the 1.55 Ohm filament resistor. A 171A power tube may be used in the power stage with the proper B supply of 180 Volts and 40 1/2 Volts C. A 112A tube using 135 Volts of B and 9 Volts of C is recommended however, for most economical operation.

Models 811, 811X, 1111, 1111X (1931)

R.F. and Oscillator Transformers

The antenna and R.F. coupling transformers are properly shielded and the oscillator unit is assembled in a shield together with the 600 K.C. tracking condenser, the .00075 condenser (C16) and the resistor (R14) to ground. This method of assembly has eliminated radiation which is a common fault in superheterodyne receivers.

These three units are matched within one microhenry. Each coil has a paint mark inside the coil form near the terminal lugs and the color of this mark indicates the inductance of the coils. The antenna, R.F., and oscillator units in each receiver have the same color and it is necessary that the color be mentioned when ordering a transformer for replacement.

Tuning

The primary and secondary of both intermediate transformers are tuned with adjustable condensers which remain fixed after the transformers have been tuned to exactly 175 kilocycles.

The oscillator has an adjustable tracking condenser which is adjusted at 600 kilocycles and remains fixed thereafter.

Condensers and Resistors

Three blocks contain the majority of condensers. The choke in the plate circuit of the second detector tube is, also contained in one of these blocks. The common leads of condenser blocks No. 1 and No. 2 are grounded. C1, C4, and C6 in block No. 3 have a common lead which is grounded, and the choke, and C3 in this block have a common lead connected to the plate of the 2nd detector.

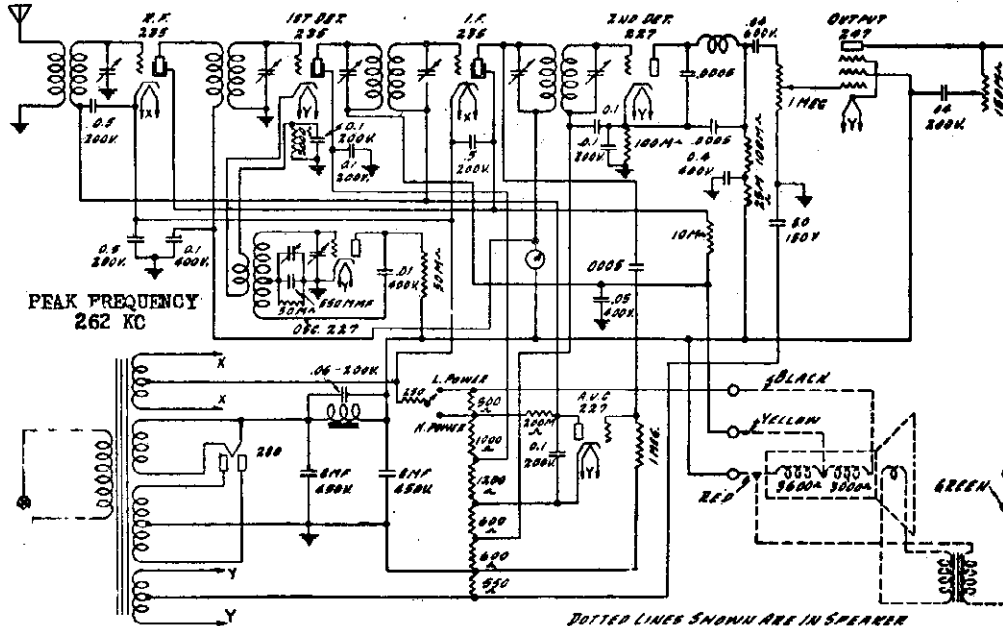

ANALYZER CHART

All voltages taken with a 1,000 ohm per volt voltmeter on the scale indicated in the column headed "Meter Scale." Turn the volume all the way on and connect the antenna and ground leads together. The grid, plate, and screen grid voltages are measured to cathode of the '24 and '35 tubes and to filament of the '47 tube.

The grid voltage on the '27 oscillator cannot be taken except with a very sensitive, low scale voltmeter. The voltage is approximately .05 volts when the A.C. line voltage is 110 volts.

25 Cycle Chassis No. 1238X

For 25 cycle sets remove the .06 Mfd. condenser across the filter choke and use No. U-3084 power transformer instead of U-2783.

In order to provide satisfactory tracking with the K. F. and 1st detector tuned circuits the oscillator is provided with a 600 K. C. and a 1400 K. C. trimmer condenser. The 1400 K. C. trimmer condenser is located on top of the tuning condenser and is connected across the tuning condenser. The 600 K. C. trimmer condenser is across the 550 Mmf. fixed condenser and the adjusting screw is in front of the first I. F. can on top of the chassis.

The I. F. transformers are small universal wound coils mounted on a piece of tubing. The I. F. tuning condensers are small mica condensers. The coil tubing standards and condensers are mounted on porcelain bases and are enclosed in metal cans located on top of the chassis. The adjusting screws of the four I. F. tuning condensers are reached from the bottom of the chassis.

Voltages

Check the voltages at the sockets to see if the power system is delivering the correct voltages. The antenna and ground should be disconnected. The shield should be on. The tester plug can be inserted in the sockets and the shield placed over it. When the plug is inserted in the oscillator socket, the cable must be doubled back over it in order to get the shield back on. When reading the voltages of the 1st detector bring the grid cap and wire through the trimmer condenser hole in the shield. The voltage chart shows the voltages and currents with all tubes in, speaker connected and set in operating condition. The voltages will vary with individual receivers and with variations in tubes. The voltages as shown are with a line voltage of 115.

Several of the voltages as indicated in the chart cannot be satisfactorily read at the socket but should be read across the resistors at which they are developed.

DOTTED LINES SHOWN ARE IN SPEAKER

MODEL 1355 (62-1955)
 Minstrel
 Socket-Data

MONTGOMERY-WARD & CO.

Automatic Volume Control

The automatic volume control as used in this receiver varies the signal strength by changing the bias voltage of the R. F. and I. F. 235 tubes. A 227 tube is used as the A. V. C. tube. Plate, cathode and grid circuits of this tube are connected to the voltage divider resistor as shown in Fig. 1 to secure the required plate and grid voltage. In the plate circuit of this tube is a 200,000 ohm resistor. The grid circuits of the R. F. and I. F. tubes are connected to the plate of the A. V. C. tube through a 10,000 ohm resistor. The cathodes of these two tubes are connected through the 250 ohm biasing resistor to the other end of this 200,000 ohm resistor in the plate circuit (power level switch on "H" power). The grid of the A. V. C. tube is connected to the plate of the I. F. 235 tube through a .0005 condenser. The A. V. C. tube has an initial bias of 20 volts and under conditions of no signal, no plate current flows in this tube. However, when an A. C. voltage of 15 or greater is applied to the grid circuit of the A. V. C. through the .0005 coupling condenser, plate current flows and a drop is established across the 200,000 ohm resistor. This lowers the voltage of the R. F. and I. F. grids, increasing the bias and decreasing the sensitivity in proportion to the strength of the signal being received. The higher the A. C. voltage applied to the A. V. C. grid the greater the drop across the 200,000 ohm resistor and the higher the bias voltage. For weak signals, therefore, the A. V. C. does not affect the bias and maximum sensitivity is obtained, while for strong signals the bias is increased and a corresponding reduction in sensitivity effected.

The I. F. transformers are small universal wound coils mounted on tubing. The I. F. tuning condensers are small mica condensers. The coil tubing and condensers are mounted on porcelain bases and are enclosed in metal cans located on top of the chassis. The adjusting screws of the four I. F. tuning condensers are reached from the bottom of the chassis.

Servicing

The usual checking of wiring and soldered connections and checking of resistors and condensers for opens, shorts, grounds and wrong value also apply, of course, to the Super-heterodyne. In working on the receiver care should be taken that the I. F. plate and grid leads are not bent too close to the chassis as the capacity to the ground will be excessively high. Note that the R. F. and I. F. control grids are not at ground potential and a slight shock can be obtained between the grid caps of these tubes and the chassis. Do not get the antenna lead near the 2nd detector as a harmonic of the signal in the 2nd detector plate circuit may feed into the antenna system and beat with the R. F. signal causing an audible whistle.

A good check to determine if the oscillator is working is to read the voltage across the 50,000 ohm resistor. This will vary between the limits as shown in the voltage chart for the oscillator bias, depending on the frequency to which the receiver is tuned.

In order to provide satisfactory tracking with the R. F. and first detector tuned circuits the oscillator is provided with a 600 K. C. and a 1400 K. C. trimmer condenser. The 1400 K. C. trimmer condenser is located on top of the tuning condenser and is connected across the oscillator tuning condenser. The 600 K. C. trimmer condenser is across the 550 Mmf. fixed condenser and the adjusting screw is in back of the tuning condenser on top of the chassis.

MODEL 1500
(27-W, 15000)
Collegian

MONTGOMERY-WARD & CO.

The 27W Chassis uses the following tubes:
2—224's as R.F. Amplifiers,
1—227 as Detector,
1—245 as Audio Amplifier,
1—280 as Rectifier.

The two stages of screen grid R.F. amplification in conjunction with the tuned antenna stage of this chassis give a sensitivity averaging 10 Microvolts per meter while the 227 power detector used with the single stage high gain audio provides good power output, with excellent tone quality.

Volume Control

The 8000 ohm volume control is connected across the antenna and ground of the input stage. The movable arm of the volume control is connected to ground in series with the cathodes of the two 224 R.F. amplifier tubes. This method of connection gives us a dual volume control action, which varies the signal input to the antenna stage as well as the grid bias on the first two R.F. tubes. The volume control may be easily tested by taking the voltage readings from the cathode of the 224's to the ground connection and at the same time, varying the volume control. This will give an indication if the volume control is controlling the grid bias properly.

The R.F. transformers in the R.F. stages are the same as those used in the 32W and 26W chassis. The cathode, screen grid, and plates of the R.F. tubes are bypassed by the 964A bypass condenser.

The Power Detector

The power detector receives its grid bias from the voltage drop across the 50M cathode resistor (Part No. 1892). The plate of the detector is bypassed to ground through the .001 M.F. R.F. plate bypass condenser.

The audio stage consists of a high ratio audio transformer of special design. The secondary of this transformer connects directly to the 245 power tube. The audio transformer may be tested with the continuity meter of your set checker. Disconnect the primary and secondary leads from the chassis before taking continuity measurements. Test the primary and secondary for opens or shorts, and also take continuity readings between the primary and secondary terminals, and ground. There should be no readings between these terminals and the core of the transformer or chassis ground.

The tone control is connected across the primary of the output push pull transformer, and consists of 50M variable resistance in series with a .2 M.F. fixed condenser. A short in this condenser will short circuit the primary of the speaker transformer and no signals will reach the loud speaker.

The power supply of the 27W chassis is similar to that used in some of our other chassis previously described.

Two electrolytic condensers are used in the filter circuit and care must be taken that these chassis are always kept in an upright position to prevent any small amount of electrolytic leakage in the filter condensers. It is a good idea to inspect the electrolytic condensers, upon delivery of any sets, and to wipe the top perfectly dry.

25 Cycle Chassis No. 27WX

This chassis uses a 25 cycle power transformer. Otherwise the constants of the circuit are the same.

MODEL 2655, AE-10
Voltage-Data
Two Types

MONTGOMERY-WARD & CO.

COLOR CODE

Changes on this chassis have been made on several different occasions and to distinguish how one chassis differs from another, an identification mark is placed on each one changed. This identification mark is a dot of paint found on the end rivet of the tube socket strip.

Looking at the chassis from the back the mark is at the extreme left of the 226 tube socket

If the chassis has no mark it is understood that it is an early set.

Yellow Mark The chassis having the first changes may be identified by the yellow indicating mark. This involves four changes.

1. A "dual volume control" in place of the single type. The new volume control is made in two sections, with five lugs. The section nearest the chassis, having two lugs, operates exactly the same as the single volume control. The section behind the first, having three lugs, is placed in the first audio circuit to reduce the audio amplification and operates in tandem with the antenna volume control.

2. An interchange of position of the two audio transformers. The re-arrangement of the audio transformers has not altered their connections in the circuit.

3. An addition of a "dual half microfarad condenser" and two carbon resistors in the "B" circuit of the detector and first audio tubes. The 40,000 ohm black resistor with one section of the dual condenser is placed in the detector circuit (224) and the 15,000 ohm blue resistor with the other section of the dual condenser is placed in the first audio circuit (226). You will note that the yellow and blue leads in the cable connecting to the terminal strip have been interchanged.

4. A change in the location of the grounding of No. 1 lug on the condenser block. This lug is now grounded to the condenser case with a short piece of bare wire.

Red Mark
(Serial Number 39,000-42,999)

All chassis having a red mark on the rivet of the tube socket strip have all of the changes mentioned above and in addition, have a one-tenth microfarad condenser connected from ground to one side of the 110 volt line

A peculiarity that may be experienced by the addition of this condenser is a loud hum on every station tuned in only when the antenna wire coming from the set is connected to ground. This can be eliminated by reversing the plug in the socket. Also be sure your antenna is not grounded, either by some other set being connected to your aerial or through any other means.

Green Mark
(Serial Number 43,000 and up)

All Chassis with a green mark on the rivet of the tube socket strip contain the above changes and in addition have a change in the "combination phonograph switch" circuit. This changed circuit makes use

of only the audio system of the set for phonograph reproduction, whereas the original circuit included the detector tube

The Phonograph, Radio, On, and Off positions of the switch are the same as in the early sets. To obtain maximum volume and best tone quality a pick-up coupling transformer should be used to match the pick-up used.

R.F. Coils

The antenna coil in particular is a departure from the usual performance of antenna stages in other receivers. With the usual commercial type of antenna circuit, a short antenna will detune the antenna stage and reduce the sensitivity of the set accordingly. The antenna stage in this set is so constructed that it will not be affected by short or long antennas to any appreciable extent. The R.F. coils in each stage are marked with a color, according to the group in which they fall, and three coils of the same color are placed in the chassis. This color marking is a streak of paint inside the secondary coil inside the lugs. In ordering coils for replacement, be sure to mention the color of the paint on the coil so that the replacements will be of the same characteristics. If in doubt, return the coils.

Data

Top View of Chassis.

273-J

I. F. and Oscillator Units

The primary and secondary of both intermediate transformers are tuned with adjustable condensers which remain fixed after the transformers have been tuned to exactly 175 kilocycles.

The oscillator 600 K.C. tracking condenser is mounted directly in front of the oscillator coil shield on the right rear corner of the chassis base.

Holes in the chassis base allow the tuning condensers for the intermediate transformers to be adjusted with a screw-driver from the under side of the chassis.

Power-Supply,

The 25 and 60 cycle power transformers are designed for operation on any 95 to 130 volt A.C. supply without adjustment and without overloading.

The 25 cycle chassis has a special power transformer and has two 8 mfd. 450 volt dry electrolytic condensers, in parallel, instead of the one condenser, C14, shown in the schematic diagram. An 8 mfd. 450 volt wet electrolytic condenser is mounted on top of the chassis base and this condenser replaces the condenser, C17, shown in the diagram. The 25 cycle chassis differs in no other way from the 60 cycle chassis.

Replacing Rubber Drive

You will note that the Vernier tuning drive on this chassis uses a rubber pinion. Under normal operating conditions this rubber will last for a number of years. Should it become worn it can be readily replaced by loosening the set screw of the brass bushing located next to the rubber pinion and pulling out the station selector shaft. Place a new bushing in position, slip the station selector shaft in place and tighten the set screw.

Automatic Volume Control (A.V.C.)

The action of the automatic volume control tube controls the grid bias on the R.F. and I.F. tubes and consequently the amplification of those tubes. The primary of the 2nd I.F. transformer has a tertiary winding which is connected in series in the A.V.C. tube grid circuit.

A signal of sufficient strength reaching the second detector, applies a voltage on the grid of the A.V.C. tube and the voltage thus applied depends upon the signal strength.

The plate of the A.V.C. tube will draw current when the grid voltage of the tube rises in potential and the drop in plate current is applied to the grids of the R.F. and I.F. tubes through their grid returns to the A.V.C. tube plate. This results in a control of the amplification of these tubes and a practically constant receiver output.

The manual volume control adjusts the negative biasing on the control grid of the A.V.C. tube, regulating in this manner the level of the input to the second detector at which the A.V.C. action commences. Thus the manual volume control behaves virtually as an output level control.

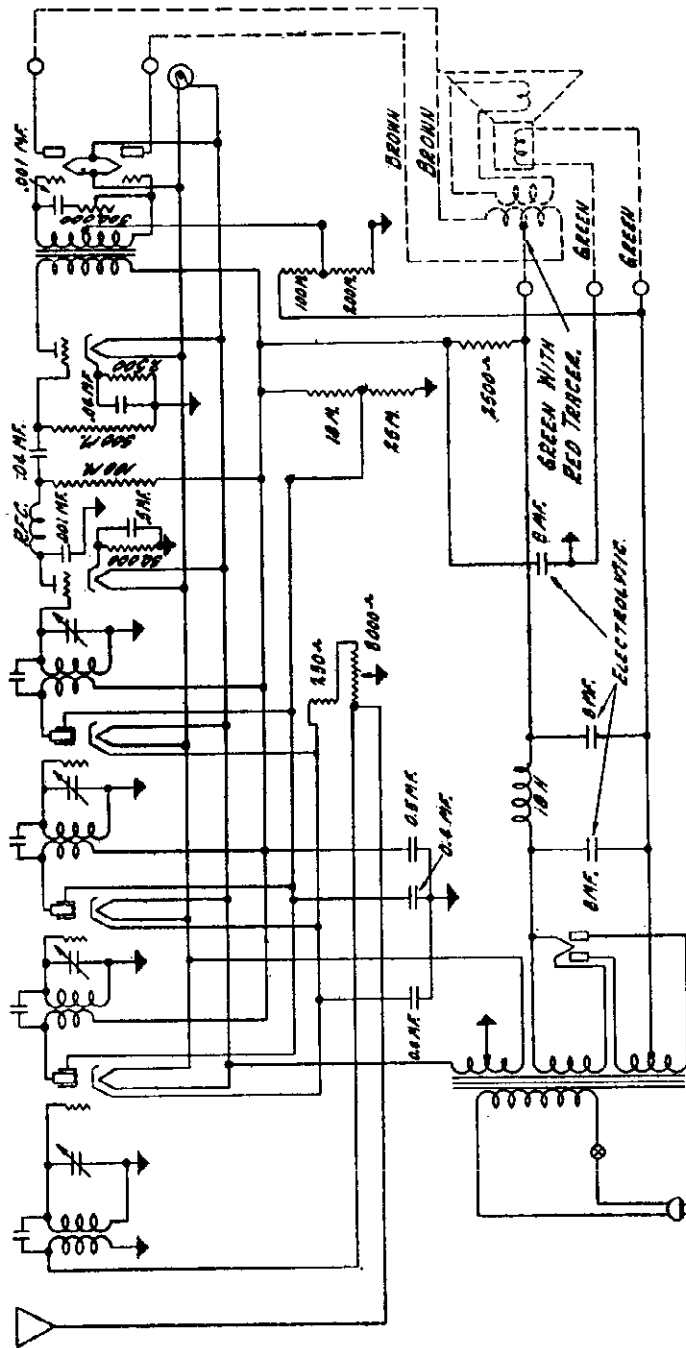

If the A.V.C. tube is defective or removed from its socket, there will be no control of the volume. Similarly, if the A.V.C. tube grid circuit is open, the plate of the tube applies a high grid bias on the R.F. and I.F. tube grids and practically no amplification is obtained from these tubes and consequently no receiver output.

A signal which is too weak to affect the A.V.C. tube grid voltage will not, of course, produce any change in plate current and the maximum amplification of the R.F. and I.F. tubes will be obtained, depending upon their grid bias as set by the A.V.C. tube plate.

Model 29 W chassis used in both the Commander and Cavalier sets is similar in all essential respects to the Airline Cortez and Coronado.

Certain changes have been made, however, which have to do chiefly with the operating voltages. The schematic diagram as compared with the diagram of the Cortez will show clearly where these changes have been made, and the operating voltages chart will show the effect that the changes have had in the voltages at the various tube sockets. In performance this chassis is quite similar to the Cortez, with the exception of slightly less power out-put when operated with the volume control full on.

Servicing instructions which apply to the Cortez also apply in the 29 W chassis. Do not forget, however, that in making any measurements with the set analyzer on the 29 W chassis, that the voltages are widely different from those used in the Cortez.

PHILCO RADIO & TELEVISION CORP.

MODEL 4
Alignment
Chassis

The adjustment of the compensating condensers in the Model 4 is done with the aid of a modulated oscillator, accurately calibrated at 3600KC. A high grade crystal controlled oscillator, of this type, Philco Model No. 091, can be obtained on order from the Philco National Service Station. The various harmonics and image frequencies of this signal are used to adjust the compensating condensers at the different short wave dial settings. If the oscillator is off frequency, the harmonics and image frequencies will be off correspondingly.

Remove the converter from its cabinet. Connect the Model 4 to the broadcast receiver in the usual manner, with the ground wire connected and the aerial disconnected. A Model 112 is preferable as this offers greatest sensitivity. It is important that the broadcast receiver be accurately calibrated at 1000KC and that the dial be set exactly at this point.

1. **Adjusting at 3.6 megacycles on lower scale**—Place the oscillator in operation and couple it with a wire to the antenna connection of the converter. Be sure that the oscillator is grounded. Set the dial at 3.6 megacycles on the lower scale and set the frequency control switch of the converter in its proper position. Carefully adjust the "3.6M" compensator shown in the illustration above, by means of a fibre wrench, Philco part 3164, until maximum signal is heard in the loudspeaker. It may be necessary to reduce the oscillator output by removing the oscillator from the coupling wire in order to obtain a faint input signal, the maximum strength of which can be readily determined by ear.

2. **Adjusting at 1.6 megacycles**—Set the dial at 1.6 megacycles and adjust the "1.5" compensating condenser in the same manner as described above.

3. **Adjusting at 7.2 megacycles**—Set the dial at 7.2 megacycles and set the frequency control switch in its proper position for the middle dial scale. Connect the oscillator output direct to the antenna terminal of the converter. Adjust the "8.5M" compensating condenser for maximum output in the loudspeaker as described above.

4. **Adjusting at 3.6 on middle scale**—Turn the dial to 3.6 on the middle scale and adjust the "3.6M" compensator as described above.

5. **Adjusting at 18. megacycles**—Set the dial at 18 and the frequency control switch in its corresponding position. Adjust the "19" compensator as described above. More than one signal will be heard as the adjustment is being made. Be sure to adjust for the one which is heard second as the compensating condenser capacity is reduced from its maximum (adjusting nut all the way in). When this adjustment has been made correctly, the oscillator signal can be heard at 18, 16, 14.4 and 12.4 megacycles. This adjustment is the most critical of any, and will require more care in getting the correct point.

6. **Adjusting at 8.8 megacycles**—Turn the dial to 8.8. Adjust the "8.5H" compensator in the manner described above.

RE-SETTING 1000KC WAVETRAP

A wavetrapp tuned to 1500 kilocycles is connected in the antenna circuit of the converter for the purpose of suppressing any possible interference from nearby stations which might be broadcasting at or near 1000 kilocycles. If it is impossible to find a point between 950 and 1050 KC at which interference is not heard, the wavetrapp should be re-adjusted by means of the fibre wrench until the interfering station is tuned out.

34	Resistor (two 50,000 ohms, 25-40 cycles)	3526
	Base*	3021
	Chassis*	40000

PHILCO recommends that under no circumstances should any attempt be made to adjust the compensating condensers in the field, unless proper equipment is available, and that where such is not the case the unit should be turned over to a Philco Distributors Service Department. The adjustment is extremely critical and requires more time and patience than the ordinary broadcast receiver. All of the compensating condensers are accessible only from the bottom of the chassis. The short wave converter is accurately adjusted at the factory prior to shipment.

*Includes matched oscillator coil and detector transformer.

MODEL 20, 20-A
Voltage
Values

Models 20 and 20-A Receivers

Model 20 Receivers are for Operation on 105-125 volt, 50-60 cycle AC Lines.
Model 20-A Receivers are for Operation on 105-125 volt, 25-60 cycle AC Lines.

Bulletin 28 covers the first few weeks' production of Models 20 and 20-A. These Receivers can be identified as having one or two compensating condensers. The later models have three compensating condensers fastened to the tuning condenser housing and are covered by Bulletin 36.

MODEL 20, 20-A
Chassis
Schematic

PHILCO RADIO & TELEVISION CORP.

DIFFERENT CIRCUIT ARRANGEMENT FOR MODEL 20-A

Model 20-A for use on 25-60 cycle lines is wired differently than the Model 20. The plate supply lead for the two 24 R. F. Tubes is taken from the low side of the Speaker field Coil. The lead "D" to the 24 tubes should be changed to "J" for the Model 20-A only. This will change the plate voltage from 250 volts to 115-125 volts. The plate current readings will also be lower than those given in the table.

30	Detector Rectifier	2.0
30	Detector Amplifier	2.0	15
30	1st Audio	2.0	90	Note 1	.002	..
31	{2d Audio }	2.0*	150	24	.008	..
31	{Push-Pull }	2.0*	150	24	.008	..

*These readings reversed with respect to other Filament Voltage readings.

NOTE 1. With volume control in "Off" position, approximately 4 volts; with volume control full on, less than 1 volt.

Always use high-resistance voltmeter, preferably 1000 ohms per volt, when checking voltages in the Receiver. For reading plate and screen voltages, use a 250- or 300-volt scale. Voltage readings taken with meters having less than 250,000 ohms resistance will be lower than voltages given in the table.

When testing a Model 30 Receiver, all tubes must be in their proper sockets. The speaker must be connected and the tube shield must be fastened in place. The readings in Table 1 were taken using "A," "B" and "C" batteries.

Either the ear method or an output meter can be used while adjusting.

With the Receiver set up for operation, adjust the oscillator signal to a frequency between 1200 and 1300 kilocycles. This corresponds to 120 and 130 on the Receiver tuning scale.

Use a weak signal and tune the Receiver sharply to the oscillator note. The volume control should be turned on "full."

Adjust the compensating condensers, starting with the fourth condenser ⑳ in (Fig. 2.) If using the ear method, adjust the condenser to the loudest signal. If using an output meter, adjust for the maximum reading.

Next adjust the third, then the second, and finally the first. It will not be necessary to reduce the oscillator signal as the successive condensers are adjusted. Reduce the volume of the Receiver with the volume control.

In each step, always adjust for the maximum signal or reading.

PHILCO RADIO & TELEVISION CORP.

Numbering of Philco Coils

For the purpose of identification, Philco coils are being code numbered. These numbers are stamped upon the mounting bracket before the part leaves the National Service Station. The following is a list of these coils (Dated Jan. 1932)

The various compensating condensers used in the models 35, 70, 270, 370, 390, 112, and 212 have been changed so as to include a bakelite mounting board on which the code letter of the condenser appears. In the case of the I. F. compensating condensers, which have been used in conjunction with a parallel fixed condenser, the new compensating condensers have been increased in capacity so that the fixed condensers are no longer required. For replacement purposes, if desired, the new compensating condensers can be substituted on earlier sets for the earlier combination of a fixed and an adjustable condenser.

Standard Compensating Condensers

The low frequency compensating condensers have been changed with respect to the bakelite mounting, but their capacity remains unchanged, thereby requiring the parallel fixed condenser as in the past.

All of these new condensers can be identified by the letter which is stamped on the bakelite mounting board. For example part 04000-E has the letter E stamped over the surface of the mounting board; part 04000-F has the letter F stamped on the board.

The following table lists the part numbers of the various new condensers, their identification code letter, capacity range, where used, the superseded part number, and the part number of the parallel fixed condenser when one is still used.

(#98 - Dated Sept. 1931)

MODEL 41 DC, 42 DC
Chassis
Changes

PHILCO RADIO & TELEVISION CORP.

Changes in Models 41 and 41-E Receivers

Changes in the circuit of the Model 41 Receiver went into effect July 31, 1930, and should be noted on the wiring diagram

The R. F. by-pass condenser, Part No. 3615-G, or 3584-D, used to by-pass the plate supply of the R. F. tubes should be changed to Part No. 3615-B. In Service Bulletin 16 this condenser is shown as (18) and is connected between the lead "P" and condenser (9).

The new condenser No. 3615-B has the same capacity as the condenser formerly used, but in addition has a 250-ohm resistor section. One end of the condenser will be grounded through the hold-down screw of the condenser. The other terminal of the condenser is the terminal at the other end of the condenser. This terminal is also common to the resistor winding and should be connected to the point "P" shown on the schematic.

The middle terminal on the condenser is the other terminal of the resistor section, and should be connected to the R. F. coils (11) and (15).

With these changes made in the schematic, the plate supply for the first two "24" tubes will come from "P" through the resistor and then through the two R. F. transformers. The end of the resistor nearest "P" is by-passed through the condenser to ground.

PHILCO RADIO & TELEVISION CORP.

MODEL 50, 50-A
Adjustment
Parts List

ADJUSTMENT OF MODELS 50 AND 50-A

Adjustment of the compensating condensers in the model 50 should be done with the aid of a good oscillator for the R.F. signal. The oscillator lead should be connected to the "ANT" terminal of the receiver. A good ground connection must be made from the receiver to the grounded side of the oscillator and to a water or radiator pipe.

Either the ear method or an output meter, connected across the speaker voice coil terminals can be used while adjusting.

When the Receiver is set up for operation, adjust the oscillator signal to a frequency which is approximately 1400 kilocycles.

With the volume control advanced to maximum, and using a weak oscillator signal, tune the receiver sharply to the oscillator note.

Adjust the third R. F. compensating condenser by means of the Philco fibre wrench, part 3164, for maximum output signal. If an output meter is being used, adjust for maximum reading.

Next adjust the second R. F. compensating condenser and finally the first. In each case, always adjust for maximum signal or reading.

A resistor of 10,000 ohms is used in place of an r-f choke in the detector plate circuit. Two bypass condensers, with mid-junction grounded are connected across the resistor.

A fixed condenser is connected between the plate of the pentode tube and ground.

PHILCO RADIO & TELEVISION CORP.

MODEL 51, 51-A
Schematic

ARRANGEMENT OF WIRES

The placing of certain wires in the receiver will effect the operation to a marked extent. The red wire from the primary of the first I. F. transformer (2), Figs. 1 and 2, to the .05 mfd. condenser (9), Figs. 1 and 2, must come straight down to the corner of the I. F. tube socket, then straight up to the condenser lug.

The wire from the plate of the detector-oscillator tube to the coupling compensating condenser (1), Figs. 1 and 2, must be away from the chassis at the side.

One of the peculiarities of the Model 51 circuit is the fact that the oscillator tube will often stop oscillating if the rotor plate of the tuning condenser is touched. The same condition will result, if the condenser is tuned all the way to the low frequency end of the dial, allowing the metal spacer on the rotor plates to touch the ends of the stator plates. Normal operation will be resumed, if the power switch is snapped off and on again, or if the set is tuned to the high frequency end of the dial. An insulated wire is placed around the metal spacer on one set of rotor plates to prevent them from touching the stator. Later model 51s have a small fibre insulator of special design to replace the wire.

The coupling condenser and the two i-f trimmer condensers are located at the rear of the chassis, near the combination 1st detector-oscillator tube. Reading from left to right, facing the rear of the chassis, the condensers are "coupling", "2nd i-f" and "1st i-f".

MODEL 51, 51-A
Adjustment
Chassis

The adjustment of the Model 51 Receiver requires the use of a 175 K.C. oscillator and a broadcast oscillator such as the Jewell 560.

Set up the receiver for operation with the ground wire attached, but the aerial disconnected. Connect the ground wire of the oscillator to the receiver ground terminal. Connect the output meter (low terminals) across the speaker voice coil terminals.

Intermediate Frequency or I.F. Adjustment—Place the oscillator in operation at 175 K.C. Remove the tube shield and attach the oscillator output lead to the control grid terminal on top of the detector oscillator tube (see illustration above).

With the receiver volume control on full, adjust the oscillator output until the output meter reads about 1/2 scale deflection.

Using a Philco-fibre wrench, part 3164, adjust the 2nd I.F. compensating condenser for maximum reading in the output meter. The illustration above shows the positions of the various compensating condensers. Next adjust the first I.F. compensating condenser, and finally adjust the coupling condenser. Remove the oscillator connection from the grid terminal of the detector oscillator tube, and replace the clip on the tube.

Detector Condenser—Connect the oscillator to the "Ant." terminal of the receiver chassis. Place the oscillator in operation at 175 K.C. Turn the station selector of the receiver to exactly 1400 K.C. Adjust the detector compensating condenser for maximum reading in the output meter.

If the receiver is so far out of adjustment that the signal is not audible, it may be necessary to set the oscillator for 1400 K.C. on the broadcast frequency setting. After making this adjustment, again set the oscillator at 175 K.C. The adjustment of the detector condenser will determine the position on the Philco scale where the eighth harmonic of 175 K.C. (1400 K.C.) will be tuned in. It must be tuned in at exactly 140 on the Philco scale.

Antenna Condensers—With the oscillator still set at 175 K.C. and the tuning dial at 1400 K.C., adjust the second antenna compensating condenser for maximum reading in the output meter, and then adjust the first antenna condenser.

Low Frequency Condenser—Set the broadcast oscillator to exactly 600 K.C. and turn the receiver dial to exactly 60 on the scale. Adjust the low frequency condenser for maximum reading in the output meter.

After making this adjustment, it will be desirable to check the detector compensating condenser adjustment again. Set the oscillator at 175 K.C. and receiver at 140 on the scale. Adjust again for maximum reading in the output meter.

Several changes in wiring and part numbers have been made in model 70. The filter choke, part 4951 has been changed to part 4819, the same choke as used in the model 21. On the 50-60 cycle models, a .09 mfd. condenser, part 4989-J, is connected across the filter choke, part 4819. On the 25 cycle models, this condenser should be .18 mfd., part 4989-H, ungrounded. The two 240,000 ohm resistors, part 4410, Nos. 32 and 35 Service Bulletin No. 57 and Nos. 25 and 29, Service Bulletin No. 85, should be of the Continental Carbon type. This is the resistor without the metal ends.

Part Numbers on Service Reports

It is highly important that the complete part number including the letter, of defective parts be specified on all of your service reports. Many parts have a letter after the part number as listed in the service bulletins. Other parts—namely, power transformers, audio transformers, filter chokes, field coils, electrolytic condensers, and volume controls are listed in the service bulletins without a letter, but actually have this letter stamped on the part itself after the part number.

Adjusting Superheterodynes

PHILCO RADIO & TELEVISION CORP.

Adjusting Philco Superheterodynes

The compensating condensers in every Philco Receiver are carefully adjusted before the set leaves the factory. Under ordinary circumstances they should never have to be re-adjusted in the field. Extremely rough handling during shipment, or a slight change in some of the electrical characteristics of the radio circuit may in some cases make re-adjustment necessary.

The indications that the set may require re-adjustment are poor sensitivity, poor selectivity and dial readings in kilocycles off more than 20 K. C. In some cases, an unstable condition of the set with a tendency to squeal or howl on certain sections of the dial may also be an indication of improper adjustment.

Under no circumstances should a re-adjustment be attempted unless the necessary equipment is available and unless the proper instruction has been received. Your distributor will gladly assist you in both of these matters.

The general method of adjusting the compensating condensers in all Philco superheterodyne receivers is the same. Once this procedure is understood for one model, it can be applied with but little change to the various other Philco models. By means of the instructions below and by reference to the different illustrations, the complete adjustments can be made on all Philco superheterodynes.

EQUIPMENT.

The following equipment is needed:

1. Intermediate frequency oscillator accurately calibrated at 175 K. C. and 260 K. C. The Philco Oscillator Model 095 is recommended.
2. Output meter. The oscillator mentioned above is equipped with an output meter.
3. Philco fibre wrench, part 3164.

INTERMEDIATE FREQUENCY OR I. F. ADJUSTMENTS.

The adjustment of the I. F. compensating condensers should be done in the following manner:

1. Make the necessary connections between the oscillator and the receiver as shown in the illustration, Fig. 1. The connections consist of (a) the ground wire to the GND terminal of the radio set and to the G terminal of the oscillator; (b) the A terminal of the oscillator to the grid of the first detector tube (tube shield in place and first detector grid clip removed); (c) output meter terminals to the primary of the output transformer (this connection is obtained at the speaker plug and socket through the Philco plug-in adapter, part 6095); (d) power cord of receiver to the electric power outlet after all other connections have been completed.
2. Turn on the radio set and the oscillator. For Philco models of the 70 and 35 series, the oscillator switch should be placed in the 260 K. C. position. For models of the 111, 112, 90 and 51 series, the switch should be placed in the NORMAL-MAXIMUM switch position. Turn the radio volume control to Maximum.
3. Adjust the oscillator control (attenuator) until a reading is obtained on the output meter of approximately $\frac{1}{2}$ the scale deflection. By means of the Philco fibre wrench, part 3164, adjust the various intermediate frequency condensers, one at a time, to obtain maximum reading in the output meter. Locations of all compensating condensers are shown in the illustrations on pages 3 and 4. It is desirable to start with the last I. F. compensating condenser in the circuit (2nd I. F. secondary in the case of the 112) and progress in the adjustments toward the first. It may be necessary while the adjustments are being made, to lower the setting of the oscillator control from time to time so as to keep the output meter reading within the scale range.
4. After these adjustments have been completed, remove the oscillator connection from the grid terminal of the first detector tube and restore the grid clip connection to this terminal.

COUPLING CONDENSER.

Adjust the coupling condenser in the Model 51 at 175 K. C. in the same manner as the I. F. condenser.

HIGH FREQUENCY ADJUSTMENTS. Improper adjustment of the high frequency compensating condenser is characterized by weak reception and poor selectivity at the high frequency end of the dial and by dial readings being off by more than 20 K. C. at this end of the dial. Proceed in the following manner:

1. Connect from the A terminal of the oscillator to the ANT terminal of the broadcast receiver. All other connections remain the same as for adjustment of the I. F. compensating condensers. See Fig. 2 for complete connections.
2. Set the switch on the oscillator to 175 K. C. Set the dial of the receiver to exactly 140 (1400 K. C.). The eighth harmonic of 175 K. C. will be received at this point. Turn on the volume control to maximum. Turn on the oscillator and adjust the control until a $\frac{1}{2}$ scale reading is obtained on the output meter. If the receiver is badly out of adjustment, it may not be possible to obtain such a reading, in which case the meter reading must be disregarded temporarily and the adjustments made by ear.
3. Carefully adjust the high frequency compensating condenser for maximum reading in the output meter or for maximum volume if the output is not great enough to be read on the meter.

Fig. 2

4. When making this adjustment, it may be found that a given position of the adjusting nut can be obtained at which maximum reading is noted, but that the meter reading decreases when the fibre wrench is lifted from the nut. Allow for this condition by turning slightly beyond the point of maximum reading, then when the wrench is removed the reading will go up instead of down.
5. After making the adjustment, turn the station selector slightly to note if any increase in volume is obtained as the set is being re-tuned. If such an increase is obtained, then the antenna, detector and r. f. condensers should be re-adjusted as described below. After this adjustment, the high frequency condenser can again be re-adjusted at 1400 K. C.
6. In some cases, when first starting to make the 1400 K. C. adjustment, it may be found that the signal from the oscillator cannot be heard at 140 because the set is so far out of adjustment. In this case, tune the set to the signal, and then adjust the Antenna Detector and R. F. condenser first. Re-adjust the high frequency condenser at 140 on the dial.

ANTENNA, DETECTOR, AND R. F. ADJUSTMENTS.

The adjustment of the antenna, detector, and R. F. compensating condensers is done at 140 on the dial in the same manner and with the same connections as for the high frequency adjustments.

LOW FREQUENCY ADJUSTMENT. The characteristics of improper adjustment of the low frequency condensers are weak reception, poor selectivity and dial calibrations off more than 20 K. C. at the low end of the dial. The low frequency adjustment is made with the same connections as for the high frequency and Antenna condenser adjustments. Proceed in the following manner:

1. With the receiver and the oscillator in operation, the latter at 175 K. C., set the Philco dial at exactly 70 on the scale.
2. With the volume control at maximum, adjust the oscillator output until the output meter reads approximately $\frac{1}{2}$ scale deflection. Adjust the low frequency compensating condenser for maximum reading in the output meter.
3. If the signal comes in stronger at a position off 70 on the Philco scale, adjust for maximum output on the meter at this "Off K. C." position of the dial. Now re-tune the set slightly to obtain any further possible increase, adjusting the compensating condenser and re-tuning the dial each time so as to bring the point of maximum output as near 70 as possible.
4. Re-set the dial to exactly 140, and re-adjust the high frequency condenser. It is possible that the adjustment of the low frequency condenser has affected the high setting of the dial slightly.

Neutralization

Neutralizing: Use a neutralizing tube as described above and a good oscillator, such as is shown on Page 17, to neutralize the Philco Receiver.

When adjusting the Neutralizing Condensers connect the test lead from the oscillator to the ANT terminal. Have a good ground connection. Turn on the oscillator. With the Receiver turned on, tune it carefully until the oscillator signal is brought in at maximum strength. Have the oscillator coupler plug in for loud volume.

Remove the third (next to the detector) R. F. Tube, and after insulating one of the filament prongs put it back into the socket. When the neutralizing tube is inserted, the volume should be quite low. To properly neutralize this stage, turn the third neutralizing condenser with a fiber wrench, first one way then the other, until the minimum signal is obtained. This adjustment for minimum signal

is very critical, and must be done with extreme care. Remove the neutralizing tube and after taking the insulating material from the filament prong put the tube back into the socket. Repeat the above procedure for the second and then the first R. F. stage. It is important that the neutralizing be done with the volume control on full.

MODEL 90,90-A
(With 2-45s)
Parts List

RANGE SWITCH

The Range Switch, No. ⑩ in Fig. 1, is placed in the NORMAL position when the Receiver is shipped. This gives great distance range and is the setting which will be found most satisfactory in practically all locations. In places far from broadcasting stations, however, the Range Switch may be changed to the MAXIMUM position. This will make the Receiver super-sensitive and will give extreme distance range. Do not use the Range Switch in the MAXIMUM position if there are one or more powerful broadcasting stations near you. In any location there will be less noise between stations with the Range Switch in the NORMAL position.

㊲	Condenser 6 M. F. Electrolytic Type (25-40) and (50-60) cycles	4916			
㊳	B. C. Resistor	4953			

Several changes in wiring and part numbers have been made in the Model 90. The filter choke part 4951 has been changed to part 4819, the same choke as used in Model 21. On the 50-60 cycle models, a .09 mfd condenser, part 4989-J, is connected across the filter chokes, part 4819. On the 25 cycle models, this condenser should be .18 mfd, part 4989-H ungrounded. The two 240,000 resistors part 4410, numbers (32) and (35) should be of the Continental Carbon type. This is the resistor without metal ends.

In the Model 90, a metal shield, part 03646, is placed in a bracket between the '47 and '80 tubes.

If electrolysis occurs on the insulation of the wire between the filter choke and one of the electrolytic condensers, unsolder the wire and cover with spaghetti.

PHILCO RADIO & TELEVISION CORP.

MODEL 90, 90-A
(With 1-'47)
Parts List

ADJUSTMENT OF MODELS 90 and 90-A

These Receivers are accurately adjusted at the Factory prior to their shipment. Under no circumstances are the adjusting condensers to be changed in the field. This alignment requires special oscillator equipment, which all Philco Distributors have. If for any reason the Receiver needs adjustment it must be returned to the Distributor's Service Department.

MODEL 90, 90-A
Alignment
PHILCO RADIO & TELEVISION CORP.

Adjusting the Model 90 Using a Jewell 560 Oscillator

Set up the Receiver for operation using standard tubes. Set the Normal-Maximum switch in the Normal position.

Intermediate Frequency Adjustment—Remove the tube shield. Remove the control grid clip of the first detector tube (Type 24 tube nearest back of the Receiver Chassis under the tube shield). Connect the "A" terminal of the oscillator to the control grid of the first detector tube. The "G" terminal must be connected to the Receiver Chassis. Turn the filament control of the oscillator on about $\frac{1}{2}$ the total movement. The middle switch must be turned to the intermediate position. The tuning control of the oscillator must be set for exactly 175 K.C., as indicated in the calibration data sent with the instrument.

Turn the volume control of the Receiver on full. Set the attenuator control so that an audible signal is received in the speaker. Connect the \pm and the low terminals of the output meter to the voice coil terminals of the speaker. Adjust the attenuator control for not more than $\frac{1}{2}$ full scale reading of the meter.

Using a Philco part No. 3164 fibre wrench, adjust the second I. F. secondary condenser for maximum reading in the output meter. Adjust the first I. F. secondary and then the first I. F. primary condensers for maximum reading in the output meter. Reduce the oscillator signal to prevent any damage to

the meter mechanism. Replace the grid clip on the first detector tube and replace the tube shield.

High Frequency Compensator—Connect the "A" and "G" terminals of the oscillator to the ANT and GND terminals of the Receiver. Do not change the oscillator setting. Tune the Receiver to exactly 140 and adjust the high frequency compensator for maximum reading in the output meter.

Antenna and Detector Condensers—With the Receiver and oscillator in the same setting, set the detector and antenna condensers for maximum reading in the output meter. If the Receiver is so far out of adjustment that the signal is extremely weak when adjusting the high frequency condenser it is advisable to temporarily check the adjustment of the detector and antenna condensers. Final adjustment of these condensers must be made as described.

Low Frequency Condenser—With the oscillator turned to broadcast frequency set the Philco scale at 60 and adjust the low frequency compensating condenser for maximum signal in the output meter. If the signal comes in off the 60 position on the Philco scale, set the Receiver slightly off the signal towards 60 and adjust the signal for maximum strength in this position. By repeating this, you will be able to bring the signal up to the 60 setting on the Philco scale.

Parts List

MODELS 112 AND 112-A

This parts list for models 112,112-A is applicable to the phonograph combination models 212,212-A. However, the following changes and additions must be recorded.

Resistor (70) in models 112,112-A is changed to resistor (76) in models 212,212-A. In addition the following are also added to the list in connection with models 212,212-A

Ⓐ	Motor (50 cycles).....	5333	Ⓒ	Radio-Phono Switch.....	4514
	Motor (60 cycles).....	4784	Ⓓ	Cord Connector Plug.....	4091
	Motor (25 cycles).....	4785	Ⓔ	Cord Connector Socket...	4124
Ⓒ	Phonograph On-Off Switch	4748		Turn Table.....	4735
Ⓓ	Pick-up Head.....	4853			

RANGE SWITCH

The Range Switch, No. Ⓒ in Fig. 3, is placed in the NORMAL position when the Receiver is shipped. This gives great distance range and is the setting which will be found most satisfactory in practically all locations. In places far from broadcasting stations, however, the Range Switch may be changed to the MAXIMUM position. This will make the Receiver super-sensitive and will give extreme distance range. Do not use the Range Switch in the MAXIMUM position if there are one or more powerful broadcasting stations near you. In any location there will be less noise between stations with the Range Switch in the NORMAL position.

 (Above Serial No. 174,001)

Fig. 4

PHILCO RADIO & TELEVISION CORP.

MODEL 112, 112-A
Alignment Notes

PHILCO MODEL 112 SUPERHETERODYNE

Using a Philco fibre wrench, part No. 3184, adjust the third I. F. condenser until the maximum reading is obtained in the output meter. Next, adjust the second I. F. condenser and then the secondary and primary condensers of the first I. F. stage for maximum reading on the meter. During these adjustments it may be necessary to reduce the signal strength by turning down the volume control of the receiver so that the needle will not be deflected beyond the end of the scale.

HIGH FREQUENCY CONDENSER - Remove the "A" terminal lead from the control grid of the first detector tube and replace the grid clip. Replace the tube shield. Connect the "A" terminal of the oscillator to the antenna post of the Receiver and the "G" terminal of the oscillator to the ground terminal of the chassis. Do not change the oscillator setting. Turn up the attenuator of the oscillator until it is all the way on. Set the Philco scale to approximately 140 (1400 K. C.); set the NORMAL - MAXIMUM switch in the Maximum Position provided the Receiver is not too far out of adjustment the eighth harmonic of the 175 note will be heard at or near the 140 position of the scale. Set the station selector knob at exactly 148 and tune the high frequency condenser until the oscillator note is peaked at exactly 140 on the Receiver scale. Next adjust the detector condenser for maximum reading on the output meter.

If the Receiver is so far out of adjustment that the eighth harmonic of 175 K. C. is not audible, it will be necessary to set the oscillator for broadcast frequencies. Set the tuning control of the oscillator at approximately 1400 K. C. (as indicated in the data furnished with the instrument), then adjust the high frequency condenser for maximum signal in the output meter. Set the first and second antenna condensers for maximum signal in the output meter reducing the attenuator setting as the signal increases to prevent damage to the meter mechanism. Turn the center control of the oscillator to intermediate frequency and reset the tuning control of the oscillator to the 175 K. C. position and proceed as outlined above. Final adjustment must be made when the oscillator is set at exactly 175 K. C. in the intermediate position.

ANTENNA CONDENSERS - With the oscillator set at the original 175 K. C. position adjust the first and then the second antenna condenser for maximum reading in the output meter.

LOW FREQUENCY CONDENSER - Set the oscillator on broadcast position and tune to exactly 600 K. C. The oscillator signal should be received at 600 on the Receiver scale. Adjust the low frequency condenser until the maximum reading is obtained in the output meter with the Receiver set at 60.

Where it is necessary to replace the tuning scale on the Model 112 Superheterodyne, put a mark opposite 55 on the tuning condenser drum. Remove the old scale and place the new one in position so that 55 is exactly opposite the above mark.

ADJUSTING THE MODEL 112 SUPERHETERODYNE PLUS USING A JEWELL 560 OSCILLATOR

Set up the Receiver for operation using standard tubes, which you know are in good condition. Set the Normal - Maximum switch in the Normal position for the intermediate frequency adjustment. Connect the Jewell pattern 560 oscillator to the Receiver.

INTERMEDIATE FREQUENCY OR I. F. STAGES - Remove the tube shield, replace the control grid clip of the detector tube with the lead from the "A" terminal of the oscillator. The "G" terminal of the oscillator must be connected to the Receiver Chassis. Replace the tube shield on the chassis.

Turn on the filament control of the oscillator about one-half the total movement. The "A" Battery of the oscillator must be replaced when it is necessary to turn this control all the way on in order to obtain a signal. Turn the center switch to the intermediate position. The tuning control of the oscillator must be set so that the oscillator signal is exactly 175 K. C. This setting can be determined from calibration data furnished with the instrument.

Turn the volume control of the receiver on full. Set the attenuator control so that an audible signal is received in the speaker. Connect the 1/2 and low terminals of the output meter to the voice coils of the speaker. Adjust the attenuator control so that not more than one-half full scale reading is obtained on the meter.

REPLACEMENT PARTS—MODELS 112, 112-A AND 112-E
(Above Serial No. 174,001)

1	Resistor (10,000 ohms)	4517	Resistor (490,000 ohms)	67	Resistor (13,000 ohms)	3766
2	First R. F. Coil	3557	By-pass Condenser (1/4 mfd.)	68	Push-pull Output Transformer	2635
3	Tuning Condenser	5385	Resistor (70,000 ohms)	69	Voice Coil and Cone Assembly	02997
4	Compensating Condenser	03489	Filter Condenser Block (50-60 cycles)	70	Speaker Field (assembled with pot and frame)	02892
5	Second R. F. Coil	04000-L	Compensating Condenser	71	Resistor (15,000 ohms)	5718
6	By-pass Condenser (.05 mfd.)	03040	Third I. F. Transformer	72	Oscillator Coil	3884-U
7	Compensating Condenser	4519	Condenser (110 mmf.)	73	Condenser (700 mmf.)	4520
8	Resistor (99,000 ohms)	4518	Resistor (51,000 ohms)	74	Resistor (50,000 ohms)	4518
9	By-pass Condenser (.05 mfd.)	4518	Resistor (51,000 ohms)	75	Compensating Condenser	04000-F
10	Resistor (99,000 ohms)	4411	Resistor (99,000 ohms)	76	Compensating Condenser	04000-F
11	First Detector Coil	3583	By-pass Condenser (.5 mfd.) 2 used	77	Resistor (13,000 ohms)	3766
12	By-pass Condenser & Resistor (.05 mfd. and 250 ohms)	4411	Resistor (99,000 ohms)	78	Resistor (1,000 ohms)	4590
13	By-pass Condenser & Resistor (.05 mfd. and 250 ohms)	3082	Condenser (250 mmf.)	79	Condenser (110 mmf.)	4519
14	Compensating Condenser	3556	Resistor (25,000 ohms)	80	By-pass Condenser (.015 mfd. double)	4095
15	Compensating Condenser	3769	Resistor (99,000 ohms)	81	Power Transformer (115 volts 50-60 cycles)	5594
16	Compensating Condenser	3768	Resistor (490,000 ohms)	82	Power Transformer (115 volts 25-40 cycles)	5595
17	First I. F. Transformer	3793-F	Condenser (.015 mfd.)	83	Power Transformer (230 volts 50-60 cycles)	5596
18	Compensating Condenser	4060	Volume Control	84	Resistor (2 ohms)	03513
19	By-pass Condenser (.05 mfd.)	3615-B	By-pass Condenser (.05 mfd.)	85	1-in. Control Pot. (w/ometer)	5650
20	Range Switch	3342	Resistor (3,000 ohms)	86	Electrolytic Condenser (100 u.f.d.)	4916
21	By-pass Condenser (.05 mfd.)	3116	Tone Control	87	Filter Choke	5643
22	By-pass Condenser & Resistor (.05 mfd. and 250 ohms)	3615-B	Push-pull Input Transformer	88	Pilot Light	3463
23	Second I. F. Transformer	03039	Resistor (25,000 ohms)	89	Electrolytic Condenser (6 mfd.)	4916
24	Compensating Condenser	04000-J	Resistor (25,000 ohms)	90	Resistor (2 sections 70 ohms each)	3764

47	Output	2.5**	205**	220**	.7**	..	28**
80	Rectifier	4.5	260/Plate				

*The voltage readings of the short wave unit were taken from the under side of the chassis, using a Weston multi-range voltmeter, 1000 Ohms per volt. The radio set tester cannot be used, either for voltage or plate current readings because of the effect of the long leads through the set tester cord.

**These readings must likewise be taken from the socket terminals on the under side of the chassis unless the set tester is especially equipped with an adapter for testing pentode tubes.

All the above readings were taken with volume control at maximum.

Table 2—Power Transformer Voltage

Terminals	A. C. Volts	Circuit	Color
SHORT WAVE UNIT			
4-5	105 to 125	Primary	Black
1-3	2.5	Secondary	Yellow

				Electrolytic Condenser (6 mfd.) 50-60 cycles	4916
				Electrolytic Condenser (10 mfd.) 25-40 cycles	5142
				Line Cord and Plug	L-943
				Tube Shield	03987
				Bezel (Broadcast)	5008
				Bezel (Short Wave)	5178
				Knob (Large)	03063
				Knob (Small)	03064
				Knob (On-Off Switch—Broadcast)	03437
				Knob (Control Switch—Short Wave)	5811
				Spring (For Small Knobs)	4147
				Spring (For Large Knobs)	5262
				Grid Clip	4897
				Five Prong Socket Assembly	4956
				Four Prong Socket Assembly	4955
				Dial Complete (Broadcast)	03031
				Dial Complete (Short Wave)	03890
31	Filament Transformer	5924			
	(50-60 cycles)	5906			
	(25-40 cycles)	5923			
	(50-60 cycles, 230 volts)	5924			
32	On-off Switch (Assembled with 19)	5796			
33	Volume Control	5039			
34	First R. F. Transformer	03082			
	Tuning Condenser (50-60 cycles)	03076			
	Tuning Condenser (25-40 cycles)	03077			
35	Compensating Condenser—Antenna—Part of Gang Condenser Assembly	03083			
36	First Detector Transformer	03083			
37	Compensating Condenser—Detector—Part of Gang Condenser Assembly				
38	Compensating Condenser—First I. F. Primary	04000-J			
39	First I. F. Transformer	03091			
40	Compensating Condenser—First I. F. Secondary	04000-H			
41	Second I. F. Transformer	03092			
42	Compensating Condenser—Second I. F.	04000-K			
43	Resistor (250 ohms Combined with .09 mfd. Condenser)	4989-E			

*Includes matched oscillator coil and detector transformer.
**These parts replaced on later production by .0018 mfd. condenser, part 6018.

MODEL R-4, R-6 AC
Chassis
Voltage

Service work in conjunction with this receiver will be very similar to that of other table type receivers. However, there are several new features of this model which require some consideration.

The second I.F. transformer in this receiver is of the untuned variety, making the set slightly less sensitive and selective than the R-7. This decreased selectivity permits the omission of the 600 K.C. adjustable capacitor used on the R-7, R-10 and other Super-Heterodyne receivers. When alignment adjustments are necessary, it is therefore only necessary to tune one I.F. transformer and the three tuning capacitors. The I.F. transformer is adjusted at 175 K.C. and the tuning capacitors at 1400 K.C. In the case of the latter, the dial should be set at 1400 as well as the oscillator and the three screw adjusted for maximum output. This will permit the dial to read very accurately.

116-VOLT LINE

MODEL R-5-X
Parts List
Notes

R. C. A. VICTOR CO., INC.

Model R-5-X

Models R-5, R-5X (1931)

The antenna and ground are connected to each side of a 20,000 Ohm potentiometer. The moving contact of the potentiometer is connected to the primary of the first R.F. transformer through a .00013 MFD. condenser, the other side of the transformer being connected to ground. The action of the potentiometer, reducing the voltage applied to the grid of the first R.F. tube, constitutes that of a volume control. The secondary of the R.F. transformer is connected to the grid circuit of the R.F. Radiotron UY-224, which is tuned by one unit of the gang condenser. The plate circuit of this tube works into the primary coil of the 2nd R.F. transformer.

The detector is of the regenerative, grid bias type and its output is coupled by means of resistance coupling to the output Radiotron RCA-247. The regenerative feature of the detector is un-

usual in that it uses two regeneration coils. One of these resonates at a low frequency and improves the sensitivity at that end, while the other has but few turns and brings up the sensitivity at the high frequency end.

The output stage uses the RCA-247 Output Pentode which gives a high undistorted output—2.5 watts—together with a high gain in the stage.

The grid bias for this tube is obtained by using a portion of the drop across the reproducer field. Due to the fact that the plate current of the RCA-247 represents the greatest portion of the total plate current, using the drop across the field acts as a semi-self biasing arrangement.

Plate and grid supply to all tubes is supplied through the use of Radiotron UX-280. The filter is of the "brute force" type. The reproducer unit field coil functions as the reactor. One electrolytic 10 MFD. capacitor and one paper 2 MFD. capacitor act as filter capacitors.

LINE-UP CAPACITOR ADJUSTMENTS

Two adjustable capacitors are provided for aligning the two tuned circuits at the high frequency end of the scale. The following procedure may be used for making any readjustments that may be necessary.

A. Procure an Oscillator giving a modulated signal at exactly 1400 K.C. Also procure a special socket wrench such as RCA Victor Stock No. 3007.

B. An output indicator is necessary. This may be a current squared thermogalvanometer connected to the secondary of the output transformer in place of the cone coil or other types of output indicators.

C. Turn the station selector until the knob reads exactly 0. Then remove the chassis from the cabinet being careful not to disturb the setting of the dial. The gang condenser rotor plates should be fully meshed with the stator plates. If not, then the dial drum must be adjusted until such a condition exists. Replace the chassis in the cabinet.

D. Place the oscillator in operation at exactly 1400 K.C. and couple its output to the antenna lead. Set the dial scale at 85 and place the Radiolite in operation. Place a soft pad on the bench and turn the instrument on its side. Now with the special wrench, adjust each line-up capacitor until maximum output is obtained in the output meter. Be careful to adjust the volume control or oscillator output so that an excessive reading is not obtained. Go over each adjustment a second time to compensate for any interlocking of adjustments.

REPLACEMENT PARTS

Part No.	DESCRIPTION	List Price	Part No.	DESCRIPTION	List Price
2549	Resistor—250,000 Ohms—Carbon type—Package of 5.	\$3.00	3066	Resistor—12,000 Ohms—Carbon type—Package of 5.	\$2.50
2747	Cap—Control grid contactor cap—Package of 5.	.50	3067	Variable Resistor—Regeneration Control Variable Resistor complete with mounting washer and nut.	1.50
2954	Capacitor—By-pass capacitor pack containing three 0.1 Mfd. capacitors.	.75	5817	Resistor—20,000 Ohms—Carbon type.	.90
2955	Transformer—First R.F. transformer complete with mounting washer and nut.	1.50	7054	Cord—Power cord complete with male connector plug.	1.00
2956	Transformer—Second R.F. transformer complete with mounting washer and nut.	2.00	7229	Socket—Five prong Radiotron socket complete with insulating shield—3 used—Package of 2.	.50
2957	Capacitor 10 Mfd. electrolytic type Complete with terminal, insulating washer, mounting nut and lock washer.	3.00	7230	Socket—Four prong Radiotron socket complete with insulating shield—1 used—Package of 2.	.50
3069	Switch—Operating switch complete.	.60	7231	Capacitor—Filter and by-pass capacitor pack—Comprising one 0.05 mfd., two 0.5 mfd., two 0.25 mfd. and one 2.0 mfd. condensers.	2.50
2959	Volume control—20,000 Ohm Volume control complete with mounting washers and nut.	1.50	7232	Capacitor—2 gang variable tuning capacitor.	5.00
2960	Dial—Dial scale complete with set screws—Package of 2.	.50	7234	Transformer—Output transformer—With fibre terminal board.	1.50
2961	Coil—Detector plate R.F. choke coil.	.50	7236	Cone—Reproducer cone complete with voice coil and paper ring.	1.50
2962	Capacitor—0.005 Mfd. audio coupling capacitor.	.75	8669	Transformer—Power transformer—105-125 volt, 50-60 cycle—Complete with mounting washers and nuts.	6.00
2963	Resistor—8000 Ohms—Carbon type—Package of 5.	2.50	8670	Transformer—Power transformer—105-125 volt, 25-40 cycle—Complete with mounting washers and nuts.	9.00
2964	Resistor—13000 Ohms—Carbon type—Package of 5.	2.50	8671	Transformer—Power transformer—220 volts, 50-60 cycles—Complete with mounting washers and nuts.	8.00
2965	Resistor—600 Ohms—Carbon type—Package of 5.	2.50	10134	Resistor—Mi I-tapped filament resistor—Use I on early models only.	.50
2967	Resistor—45,000 Ohms—Carbon type—Package of 5.	2.50	SPECIAL PARTS SUPPLIED ON ORDER ONLY (Not to be stocked)		
2969	Resistor—50,000 Ohms—Carbon type—Package of 5.	2.50	2979	Board—Baffle board complete with grille cloth.	.75
2970	Resistor—500,000 Ohms—Carbon type—Package of 5.	2.50	2980	Escutcheon—Station selector escutcheon complete with mounting screws.	.75
2971	Resistor—280,000 Ohms—Carbon type—Package of 5.	2.50	3058	Board—Resistor mounting board—Less all resistors, capacitors and coils.	1.00
2972	Shield—Radiotron shield complete with mounting screw, washer and nut.	.50	7235	Coil—Field coil complete with bracket and cone ring.	2.00
2975	Rivet—Eyelet rivet for mounting cone—Package of 100.	.50	9321	Cabinet—Cabinet complete—Less all equipment.	7.25
2976	Knob—Volume control or Regeneration control knob—Package of 5.	1.50	9329	Chassis—Receiver chassis complete—Less reproducer unit, knobs and Radiotrons.	27.50
2977	Knob—Station selector knob—Package of 5.	2.50	9339	Reproducer unit—Reproducer unit complete.	4.75
2978	Screw assembly—Loudspeaker mounting screw assembly comprising four screws, four washers, four lock washers, eight nuts and four eyelets.	.60	9340		
2981	Capacitor—320 Mmfd. detector plate R.F. by-pass capacitor.	.50			
3006	Capacitor—001 Mfd. Used across low frequency tickler coil.	.50			
3007	Wrench—Special wrench for R.F. line-up condenser adjustments.	1.00

* Not true reading due to Resistance in circuit

** This may be plus or minus depending on age of tubes

The RCA Victor Supernote, R-7 D.C. and the Console, R-9 D.C. are similar to the A.C. Models with the exception that the necessary changes for D.C. operation have been made. The Service Notes on the A.C. Models, therefore, apply to the D.C. Models with the exception of voltage readings and circuit diagrams.

Provision for operation at 220 volts is made by the use of a separate resistance unit which drops the voltage to 110. This unit should be located in a place that is well ventilated and it should not come in contact with any wood or cloth material other than that upon which it is resting.

An interlock is provided on the cabinet back so that access to the parts cannot be made without opening the power supply. However, when service work is being performed, it may be necessary to run jumpers from the back to the connection block so that operation of the receiver may be secured. *Never make these interlocks inoperative except under these conditions. They are designed for protection of the customer.*

RCA Victor Models R-8 and R-12 are eight tube Super-heterodyne radio receivers incorporating such features as Super-Control, Screen Grid Radiotrons, Automatic Volume Control, Pentode output tube and the inherent sensitivity, selectivity and tone quality of the RCA Victor Super-Heterodyne. Model R-8 is a table type receiver and the R-12 is of the Console type. Except for the Dial Scale, both models use the same chassis, which is also identical with that of the R-10.

A reference to the Service Notes already published on the R-11 and R-7 will give details of any service information required on these receivers.

Power Consumption 100 Watts

IS TO CHASSIS FRAME

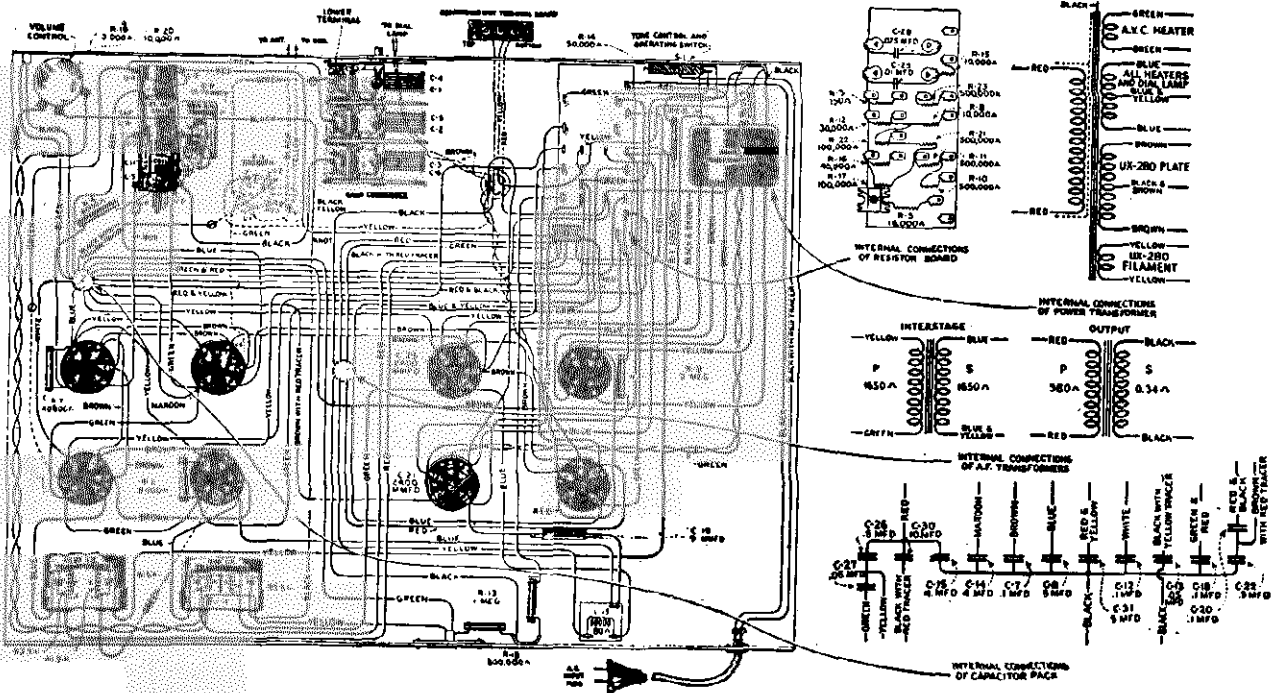

PEAK FREQUENCY 175 KC

TO AUTOMATIC VOLUME CONTROL HEATER

TO ALL FILAMENTS, HEATERS AND DIAL LAMP - EXCEPT AUTOMATIC VOLUME CONTROL

RECEIVER PARTS COMMON TO R-8 AND R-12					
2563	Resistor—6,000 ohms—Carbon type—1 watt—Package of 5	7343	Transformer—Audio transformer	2.30	\$1.85
2734	Capacitor—145 mmfd.—Package of 5	7344	Transformer—Power transformer	1.00	8.00
2746	Sockets—Dial lamp socket	7348	Board—Resistor board complete less resistors and capacitors	12.00	2.30
2747	Cap—Grid condenser cap—Package of 5	7362	Capacitor—0.025 mfd.	9.00	1.00
2749	Sockets—UY Radioset socket complete with insulation strip—7 used	8770	Transformer—Power transformer—105-125 volts, 25-40 cycles	9.00	12.00
2882	Resistor—8,000 ohms—Carbon type—1 watt—Package of 5	8771	Transformer—Power transformer—220 volts, 60 cycles	.70	9.00
2963	Resistor—UX Radioset socket complete with insulation strip—1 used	8837	Support—Receiver chassis metal mounting bracket—Package of 4	.50	.70
2970	Resistor—500,000 ohms—Carbon type—1 watt—Package of 5	2999	RECEIVER PARTS SPECIAL TO R-8	.50	.50
3002	Capacitor—8 mmfd.—Package of 4	3029	Bracket—Tuning condenser drive shaft complete	.50	.50
3024	Capacitor—9 mmfd.—Package of 2	3097	Scale—Dial drum and scale with set screws—Package of 2	.50	.50
3043	Resistor—40,000 ohms—Carbon type—1 watt—Package of 5	7843	Capacitor—3 gang tuning capacitor	8.00	8.00
3048	Resistor—500,000 ohms—Carbon type—1/2 watt—Package of 5	6189	RECEIVER PARTS SPECIAL TO R-12	.65	.65
3069	Resistor—150 ohms—Carbon type—1/2 watt—Package of 5	6190	Bracket—Dial lamp bracket and indicator—Pkg. of 2	.85	.85
3066	Shield—Radiation shield—4 used—Package of 2	6191	Shaft—Tuning condenser drive shaft complete with 3 washers—Package of 5	.55	.55
3076	Resistor—1 megohm—Carbon type—1/2 watt—Package of 5	6192	Card—Tuning condenser drive card laminum spring—Package of 10	.50	.50
3077	Resistor—30,000 ohms—Carbon type—1/2 watt—Package of 5	7438	Capacitor—Variable tuning capacitor	5.20	5.20
3078	Resistor—10,000 ohms—Carbon type—1/2 watt—Package of 5	7439	Drum—Dial drum with set screw	.50	.50
3079	Resistor—40,000 ohms—Carbon type—1/2 watt—Package of 5	7440	Scale—Dial and dial scale	.75	.75
3081	Resistor—16,000 ohms—Carbon type—3 watt	LOUDSPEAKER			
3092	Volume control—Volume control complete with mounting nut	6174	Screw assembly—Speaker mounting screw assembly—Comprising 4 screws, 8 nuts, 4 washers and 4 eyelets—Package of 1 set—For R-8	.50	.50
4095	Coil—R. F. coil—Complete with mounting bracket	8337	Screw assembly—Speaker mounting screw assembly—Comprising 4 screws, 3 nuts, 4 washers and 4 eyelets—Package of 1 set—For R-12	.50	.50
4137	Knob—Tuning control, volume control and tone control knob—Package of 5	6184	Board—Terminal board complete with 3 terminals and mounting driver—Package of 5	.50	.50
4234	Tune control—Tone control complete with mounting nut	7345	Coil—Speaker field coil assembly—Comprising coil, cone housing and magnet	5.00	5.00
4245	Coil—F. choke coil	8359	Ring—Cone retaining ring—Package of 5	.80	.80
4251	Coil—R. F. choke coil	8601	Cone—Speaker paper cone—Package of 5	15.00	15.00
6185	Resistor—100,000 ohms—Carbon type—1/2 watt—Package of 5	R-8 CABINET PARTS			
6186	Resistor—500,000 ohms—Carbon type—1/2 watt—Package of 5	X-32	Baffle board and grille cloth	.90	.90
6187	Resistor—100,000 ohms—Carbon type—1/2 watt—Package of 5	6113	Foot—Cabinet left foot—Package of 15	.50	.50
6188	Resistor—2 megohm—Carbon type—1/2 watt—Package of 5	7455	Bracket—Tuning dial excitechome complete with mounting screws	.90	.90
7054	Coil—Power coil	9402	Cabinet—Cabinet complete less equipment	16.00	16.00
7062	Capacitor—Adjustable capacitor—15-70 mmfd.	R-12 CABINET PARTS			
7298	Capacitor—0.01 mfd.	X-44	Top	4.65	4.65
7340	Transformer—First intermediate transformer	X-45	Feet	2.00	2.00
7341	Transformer—Second intermediate transformer	X-46	Front	1.10	1.10
7312	Capacitor—Compensate two 0.05 mfd., four 0.5 mfd., one 10.0 mfd., two 4.0 mfd. and four 0.1 mfd. capacitor in metal container	X-47	Structure	4.50	4.50
		X-48	Baffle board and grille cloth	.95	.95
		X-49	Metalings—Control panel moldings—Comprising 1 baffle, 1 dial, 1 excitechome, 1 tone module and 2 cone ornaments—Package of 1 set	3.00	3.00
		7441	K-ratchet—Tuning dial excitechome complete with mounting screws	1.05	1.05
		9405	Cabinet—Cabinet complete less equipment	47.30	47.30

R. C. A. VICTOR CO., INC.

MODEL R-11 AC Chassis Early

ever, due to the use of an automatic volume control tube, its action will defeat the use of an output meter. To overcome this, a "dummy" Radiotron UY-227 (one that has one heater prong removed but is otherwise O.K.) should be substituted for the tube in the automatic volume control socket. Do not make any adjustments with this tube removed from the socket. While apparently everything functions in the normal manner, the lack of tube capacity in the circuits will cause an incorrect alignment to be made.

R. F. OSCILLATOR AND I. F. ADJUSTMENTS

A reference to the RCA Victor Radiola Superette Service Notes will give the details for making correct R. F., I. F. and Oscillator adjustments. How-

MODEL R-11 AC
Chassis
Late

R. C. A. VICTOR CO., INC.

Wiring diagram of late production R-11

Late production of the RCA Victor Radiola R-11 has a slight change in the wiring, two changes in capacitor values and the addition of a 0.5 megohm resistor (R-20). Capacitor C-7 has been changed from 0.5 mfd. to 0.1 mfd. and C-13 from 0.1 mfd. to 0.05 mfd. Resistor R-20 has been added.

In previous automatic volume control receivers, the volume control was placed in the grid circuit of the automatic volume control tube, its action being to vary the control grid voltage of this tube. When operating sets of this character, the receiver jumped to full sensitivity when not tuned to a signal and if in a noisy location, this noise was very objectionable.

In this instrument, however, the volume control is not in the automatic volume control tube circuit, but in the grid circuit of the second detector. By means of it the signal voltage applied to the second detector is controlled and under no conditions can noise or other signals exceed the level for which it has been set. Electrically, the primary and secondary of the second I. F. transformer are shielded from each other so that there is no transference of energy except by means of a small pickup coil. The volume control is a potentiometer shunted across this coil which determines the amount of pickup that will be used. As a further means of controlling a strong signal, a second section is provided which places up to 10,000 ohms (R-21) in series with the tuned circuit of second detector grid. This effectively reduces even the most powerful signals received.

A 0.005 mfd. condenser connected in series with a 10,000 ohm resistor is

placed across the primary of the output transformer. This functions to reduce the third harmonic distortion, an inherent characteristic of the Pentode output tube. The direct plate and grid voltages are supplied from high voltage alternating current which is rectified by means of Radiotron UX-280. The filter is of the tapped reactor type which gives an output of well filtered D. C. The bias voltage for the Radiotrons RCA-247 is obtained by using a portion of the drop across the reproducer field. One 190,000 ohm and one 30,000 ohm resistors act as the voltage dividing resistors.

A tone control, consisting of a 0.008 mfd. condenser in series with a 200,000 ohm variable resistor connected across the two grids of Radiotrons RCA-247 is incorporated in this stage. The tone control functions to reduce the high frequency output as the resistance is reduced. At the extreme low position, the condenser and secondary of the A. F. transformer resonate at a low frequency and thereby further accentuate the bass response. The two 0.0004 mfd. condensers, connected in series with their mid-point grounded are connected across the secondary of the input transformer. The purpose of these condensers is to prevent audio oscillations and provide a high frequency audio cut-off.

The next circuit to examine is the first detector. The circuit is tuned by means of one of the gang condensers to the frequency of the incoming signal. Radiotron UY-224 is used in this stage. In the grid circuit there is present the incoming signal and the oscillator signal, the latter being at a 175 K. C. difference from the former. The first detector is biased so as to operate as a plate rectification detector and its purpose is to extract the difference or beat frequency, produced by combining the signal and oscillator frequencies. The beat frequency—175 K. C.—appears in the plate circuit of the first detector which is accurately tuned to 175 K. C.

The next stage is that of the I. F. amplifier. A single stage is used, requiring two I. F. transformers, consisting of four tuned circuits. The plate circuit of the first detector, the grid and plate circuit of the I. F. amplifier and the grid circuit of the second detector are all tuned to 175 K. C. Radiotron RCA-235 is used in this stage and its control grid voltage is also varied by means of the automatic volume control tube.

SERVICE DATA

Information pertaining to general service data for this type receiver may be obtained from the Service Notes already issued on the RCA Victor Radiola Superette.

MODEL RE-18
Schematic

IF PEAK 175 KC.

This is a combination radio and electrola incorporating a new type automatic volume control that is quiet between stations. The new type board equipment has a synchronous motor using the R. C. A. - Victor Inertia tone arm. The motor is fitted with a speed reducing gear that allows for the playing of both standard and Program Transcription Records.

In many respects this receiver is similar to the R. C. A. - Victor Model R-11 and methods similar to those used in servicing the R-11 can be applied to this Model, noting, of course, that there are some differences.

MODEL RE-13-A
Parts List

R. C. A. VICTOR CO., INC.

RCA Victor Radiola Electrola RE-18A is a nine-tube combination super-heterodyne radio receiver and electric phonograph. Except for the cabinet and tuning dial, the RE-18A is similar to the RE-18. A reference to the RE-18 service notes should be made for information relative the circuits and similar data. The replacement parts are listed below.

ELECTRICAL SPECIFICATIONS

Voltage Rating.....105-125 Volts
 Frequency Rating....25, 30, 50 and 60 Cycles
 Power Consumption.....25, 30 and 50 Cycles
 170 Watts, 60 Cycles 160 Watts
 Type of Circuit.....Super-Heterodyne using
 Super-Control Radiotrons and Push-pull Pen-
 tode output stage.
 Type and Number of Radiotrons...2 RCA-235,
 3 UY-227, 1 UY-224, 1 UX-280, 2 RCA-247—
 Total, 9
 Number of Radio Frequency Stages.....1
 Type of First Detector..Tuned Input Grid Bias
 Number of Intermediate Stages.....1
 Type of Second Detector.....Power Grid Bias
 Type of Automatic Volume Control...UY-227
 Controlled by signal voltage in turn controlling
 bias on R. F. and I. F. tubes

Type of Manual Volume Control.....Potenti-
 ometer used to regulate input to second de-
 tector
 Type of Tone Control...Variable resistance in
 series with capacitor connected across grids of
 output stage. Capacitor tunes transformer at
 "low" position
 Number of Audio Stages (Radio).....1
 Number of Audio Stages (Phonograph).....2
 Type of Magnetic Pick-up.....Low Impedance
 Type of Tone Arm.....Inertia
 Diameter of Turntable.....12 inches
 Type of Rectifier.....Full Wave
 Type of Loudspeaker.....8" Electro-Dynamic
 Undistorted Output.....4.0 Watts

FRONT

RCA Victor RE-19 is an eight tube Super-Heterodyne combination radio receiver and electric phonograph. The chassis used is similar to the R-12 with the exception that terminals for attaching a magnetic pickup are provided. The motor board assembly is similar to the RE-18. Reference to previous RCA Victor Service Notes should be made for service information relative to these assemblies. The replacement parts are given below and the diagrams on the following pages.

R. C. A. VICTOR CO., INC.

MODEL RE-20 Electrola Schematic

IF PEAK 175 KC.

Model RE-20, (1932)

Schematic Circuit

RCA Victor RE-20 is a ten tube De Luxe Super-Heterodyne combination radio receiver and electric phonograph. Except for the differences in cabinet and omission of the automatic record changing mechanism, the RE-20 is similar to the RAE-59.

Service work in conjunction with this model is similar to that of the R-50, R-55 and RAE-59. Reference to these Service Notes should therefore be made when such information is necessary. The replacement parts and the diagrams are given on the following pages.

Voltage Rating.....	105-125 Volts
Frequency Rating.....	25, 30, 50 and 60 Cycles
Power Consumption (Radio only).....	145 Watts
Power Consumption (Phonograph).....	160 Watts (Approximately)
Type of Circuit.....	A. V. C. Super-Heterodyne with Push-pull Pentode Output Stage
Type and Number of Radiotrons.....	3 RCA-235, 1 UY-224, 3 UY-227, 2 RCA-247, 1 UX-280—Total 10

The chassis and loudspeaker used in Model R-21 is identical with that used in the R-11 except for the dial and scale. A reference to the R-11 Service Notes will therefore give any information necessary in reference to circuit diagram, voltage reading and other service information. One change should be noted in later production of R-11s and all R-21s and that is the change in value of Resistor R-9 from 5 Megohms to 2 Megohms.

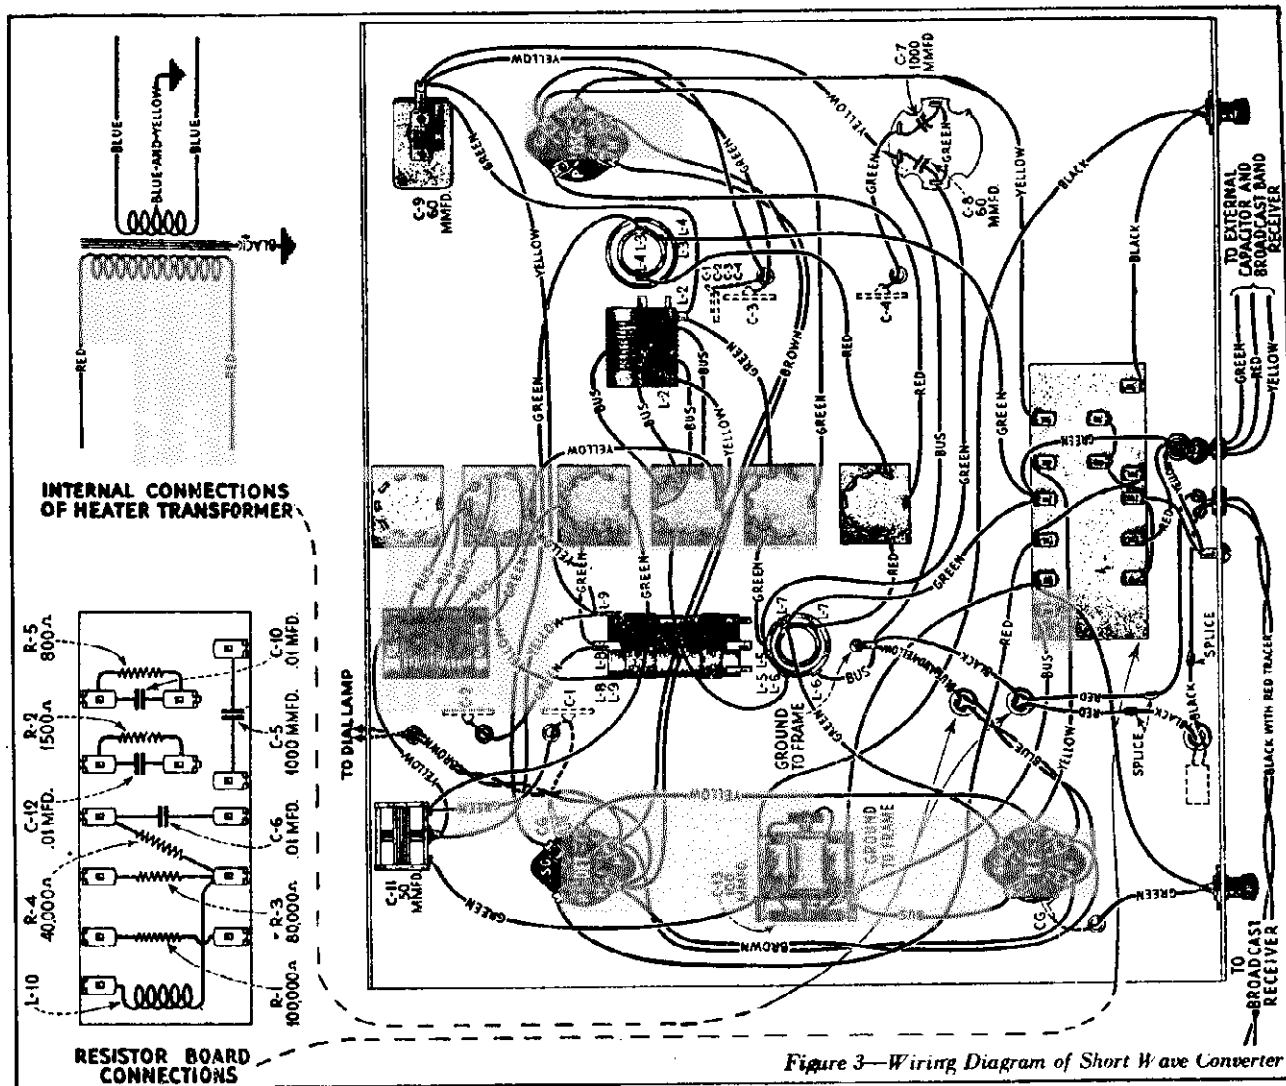

Figure 3—Wiring Diagram of Short Wave Converter

SERVICE DATA

Service information in conjunction with the broadcast receiver is covered in the Service Notes already issued on RCA-Victor Models R-8, R-10 or R-12. The Short Wave Converter is however somewhat different from the usual broadcast receiver and a discussion of its service problems will help the service man in the performance of his work.

ELECTRICAL DESCRIPTION OF CONVERTER CIRCUIT

The RCA Victor Short Wave Converter uses three Radiotrons, one UY-224 as an R. F. Amplifier, one UY-224 as a Detector and one UY-227 as an Oscillator. The purpose of the Converter is to amplify the incoming high frequency signal by means of the R. F. stage, beat it with a local Oscillator signal and produce a modulated beat frequency by means of the Detector, extract the beat frequency so that it may be amplified by means of the broadcast receiver. A special tuning Capacitor, for tuning the Oscillator and Detector stages simultaneously, is incorporated in this unit. A series of tapped coils in conjunction with a range switch provides for the shifting to various bands without interchanging coils as with the older style Converters. Also this switch changes the capacity used by the tuning capacitor so that the frequency range of each band is approximately the same. A small trimmer capacitor, known as the Resonator, is used to re-align the detector circuit with the Oscillator whenever the band is changed or the I. F. frequency is shifted. The shaft that controls the Resonator capacitor is also mechanically connected to the operating switch and the antenna switch. It is so made that when the power is turned "off," the antenna is shifted to the broadcast receiver so that broadcast reception may be obtained.

MODEL RO-23
Alignment Data

R. C. A. VICTOR CO., INC.

(1) ALIGNMENT OF CONVERTER CIRCUITS

If the Converter does not cover the bands indicated on the range switch, refer to Figure 2 and make the following adjustments. A calibrated oscillator or frequency meter is desirable although if the service man is familiar with the stations in the high frequency spectrum, the location of these stations on the scale can be used as a guide for making the adjustments. Also a calibrated short-wave receiver that has an oscillating detector may be used to check the Converter oscillator frequency. Adjust the broadcast receiver so that it is accurately set at 1075 K. C.—the short wave I. F. frequency. Set the "Range" switch at the 51.3-98.5 meter position.

Set the tuning capacitor at its minimum position. (Plates fully out of mesh.)

Place the external oscillator in operation at 5960 K. C.

Adjust the oscillator shunt capacitor C-8 so that the external oscillator will be heard in the loudspeaker or noted on an output meter.

Figure 2—Location of Adjusting Capacitors

If the calibrated oscillator is not available then a calibrated receiver may be used to receive and check the frequency of the converter oscillator. The capacitor C-8 should be adjusted until the oscillator frequency is 7035 K. C.

If a wave meter is the only standard available, then a second receiver should be calibrated from it by means of one of the several methods for doing this accurately.

If no standards are available a satisfactory adjustment can be made by increasing capacitor C-8 slightly more than the point at which the 49 meter broadcasting stations are heard when the tuning capacitor is at its minimum position on the 51.3-98.5 meter band. (With C-8 set at minimum the 49 meter band should be received.)

Now shift the tuning capacitor to its maximum position. The Converter oscillator frequency, as picked up on a calibrated receiver, should be adjusted for 4130 K. C. by the oscillator series capacitor C-7. So adjusted, the receiver will receive a 3055 K. C. signal with an intermediate frequency of 1075.

Again, if no standards are available, an adjustment of C-7 that will give a definite point of resonance near the center range of the Resonator control with the tuning dial at 50 will be satisfactory.

After checking each end of the 51.3 to 98.5 meter band, shift the range switch to the 38-51.3 meter position. Set the tuning capacitor at its minimum position (plates fully out of mesh) and the I. F. frequency at 1075. Adjust the oscillator shunt capacitor C-9 until the oscillator frequency is 9100 K. C. or the receiver will respond to a signal of 8025 K. C. If no standards are available, adjust C-9 until the 49 meter stations all fall within and near the center of the 49 meter markings on the dial. Unless this adjustment is properly made the short wave broadcasting will not fall within the bands marked on the dial.

Alignment at each end of the 51.3-98.5 meter band are also for the 98.5-200 meter band. The other alignment is for the five high frequency ranges. When these alignments are properly made, and an intermediate frequency between 1050 and 1100 K. C. is used, the Resonator control will function properly and the various short wave broadcasting services will fall within the bands indicated on the dial.

Special Notes on Effects of Aligning and I. F. Frequency Changes

Unless the line-up adjustments are carefully and properly made, the dial markings will be found to be incorrect. If it is necessary to replace the oscillator coil, the leads on the new coil should be made as short as possible and the alignment of the set checked. Also during operation it is preferable that the I. F. frequency of 1075 be used although any frequency between 1050 and 1100 will be satisfactory.

In unusual cases where local conditions preclude the use of a frequency between 1050 and 1100 K. C., considerably more variation in I. F. frequency without the loss of sensitivity will be permissible. However, the calibration will be shifted considerably, especially at the lower frequencies.

(2) DIAL INDICATOR

The indicator on the dial lamp should be so adjusted that the dial will read 100 when the tuning capacitor is at its maximum capacity position. It is important that this be checked before any alignment adjustments are made.

(3) BROADCASTING STATION HARMONICS

When tuning on the 98.5-200 meter band, the second and third harmonics of broadcasting stations will be heard and as there is no regular short wave broadcasting service on this band such signals may be discounted as better results will be obtained by listening to such programs on their regular wave band.

On the lower length bands, the short wave broadcasting stations will be received in the bands indicated for each position of the range switch with but few exceptions. Broadcasting received at other positions of the dial should therefore be viewed with skepticism unless it is definitely proved to be a short wave station and not a higher harmonic of a broadcast station.

(4) LOCAL STATION INTERFERENCE

When the receiver is located very close to a powerful transmitter, either broadcasting or code it is recommended that an antenna not exceeding 30 feet in length be used. However, if a longer antenna is necessary in order to obtain satisfactory reception, cross modulation from the local station may occur. Such a condition is evidenced by the local station coming in on unmodulated carriers on top of some short wave stations.

Under such conditions, it is advisable to use a tuned input circuit to the short Wave Converter. Such an input circuit can readily be made by winding 3 turns of No. 20 wire on a 1¼ inch tube, spacing the turns ¼ inch apart. The coil is tuned by means of a .0005 mfd. variable capacitor and should be connected from the antenna input to ground. Such a combination will tune broadly from 13.8 to 51 meters.

(5) ACOUSTIC FEEDBACK

If Acoustic feedback is experienced, it is an indication that the two chassis are not entirely supported on rubber. While with the usual broadcast receiver, such a condition is not so vitally necessary, with high frequency reception, unless each chassis is entirely floating in its rubber mounting and its shafts and knobs not touching the cabinet, howling will result.

(6) BROADCAST RECEIVER HARMONICS

When tuning through the various bands, at various points a slight breathing tone can be heard that is not a C. W. signal, but a harmonic of the broadcast receiver oscillator, being received. If an intermediate frequency of between 1050 and 1100 is used, these will not fall on any of the short wave broadcasting services. However, if they should and thereby cause a whistle, a slight shift—5 kilocycles of the intermediate frequency—will eliminate the interference. Returning the Short Wave Converter will be necessary to restore the signal to its normal intensity. Identification of these harmonics can be made by this means, a slight shift in the intermediate frequency causing them to disappear while an incoming signal will slowly diminish in volume.

R. C. A. VICTOR CO., INC.

(7) C. W. RECEPTION

Normally C. W. transmitters will not be heard unless they are modulated. However, such reception can be obtained by coupling an external oscillator loosely to the second detector of the broadcast receiver. This oscillator should be at about 174 or 176 K. C. so that a pleasing beat note will be obtained. Also a beat note may be obtained by means of an oscillator, the frequency of which is at the 1st I. F. frequency—1150 K. C.—and loosely coupled to the input of the Broadcast receiver chassis.

(8) HUM

In addition to the usual causes of hum in the broadcast receiver, the following points should be checked in relation to hum in the Short Wave Converter.

- (a) A. C. input cord near antenna wire. Keep these two leads separate as much as possible.
- (b) Slack in A. C. cord has been placed close to Converter chassis. Take up the slack near the outlet, not near the Converter.
- (c) Filament transformer center tap not connected.
- (d) One side of filament transformer grounded, thereby shorting one section of the secondary.

(9) RANGE SWITCH

A defective "Range" switch may cause any of the following conditions:

- (a) Noise. A corroded or loose wire or contact may cause excessive noise even when the switch is not being shifted. Check by removing the antenna to see if the noise decreases.
- (b) Resonator control not effective. Check the detector sections—1 and 3 from the front—for faulty contacts.
- (c) Oscillator not functioning. Check the oscillator sections—2, 4 and 5 from the front.
- (d) Shift of dial readings. Check for corroded or loose connections.

(10) ANTENNA RESONANCE COIL

An open antenna resonance coil will lower the sensitivity of short wave reception. Its purpose is to match the output of the Converter to the input of the broadcast receiver.

(11) ANTENNA TRANSFER SWITCH

The Resonator Control shaft also is used to shift the antenna from the Short Wave Converter to the broadcast receiver. Also the power switch to the converter is operated simultaneously. A failure of these switches will usually be due to the failure of the engaging lever to throw the switch. If such a condition develops, the switch may be raised so that it properly engages with the operating arm on the shaft. See that no oil or grease prevents proper connection to the shaft at the friction bearing or noise will result when the Resonator is adjusted.

(12) FLUTTER

Fluttering may be caused by either of the following:

- (a) Open capacitor C-14 or C-15. The purpose of these capacitors is to prevent flutter that may be encountered in a single Pentode receiver.
- (b) Antenna lead close to detector Radiotron. See that this lead is in its proper position and removed from the detector Radiotron in the Converter.

(13) VOLTAGE READINGS

The following voltages are obtained at the Converter Radiotron sockets when measured with the usual set analyzers.

RADIOTRON SOCKET VOLTAGES

120 Volt A. C. Line

PEAK FREQUENCY-175 KC

RCA Victor Radiola Automatic Electrola RAE-26 is a nine tube radio receiver combined with the perfected RCA Victor Automatic Record Changing Mechanism.

The Automatic Record Changing Mechanism provides for the continuous playing of ten 10-inch records. Provision is also made for a turntable speed of 33 1/3 R.P.M. as well as 78 R.P.M. This makes the mechanism adaptable for the playing of the Program Transcription Records as well as standard records, either manually or automatically.

SERVICE DATA

The Receiver assembly and Loudspeaker used in Model RAE-26 is exactly the same as that used in the R-11. A reference to the Service Notes for the R-11 will therefore give the details of any Service information required on these units.

A reference to the Service Notes on the RCA Victor Automatic Record Changing Mechanism gives details of any service work that may be required on this unit. It will also be found useful in identifying the replacement parts listed below. Figure 1 shows the schematic circuit diagram and Figure 2 the assembly wiring diagram.

SERVICE AND INSTALLATION NOTES

for

RCA Victor Automobile Radiola
Model M-30

INTRODUCTION

The RCA Victor Automobile Radiola, Model M-30, is a nine tube Super-Heterodyne radio receiver designed for automobile or motor boat use. Features of this receiver are: sensitivity and selectivity equal to that of high quality home receivers, high output Class B amplifier giving a large undistorted output with a small plate battery drain, permanent magnet dynamic loudspeaker requiring no external field supply, automatic volume control using entirely new principles of operation and extremely low battery consumption for both heater and plate supply. This feature allows the use of the automobile battery as "A" supply without imposing an additional load upon it that cannot be readily compensated for by a slight generator charging readjustment. The low plate current drain allows excellent "B" battery life. Use of the new automobile type Radiotrons eliminates the possibility of Radiotron failure due to vibration or varying heater voltage such as is encountered in automobile driving.

Figure 1—Receiver Assembly

In the design of this receiver, special attention has been given to the ease with which the installation may be made, and the elimination of interference originating in the ignition system. Thorough shielding of all parts together with proper design of the receiver makes it possible to reduce ignition interference to a negligible degree. This is done without any sacrifice in the sensitivity of the receiver.

A description of the various units follows.

RECEIVER ASSEMBLY

The receiver assembly, Figure 1, is housed in a metal case that acts as an effective mechanical and electrical shield. A bracket is provided for mounting so that dismounting is a comparatively simple operation, requiring the removal of but one screw.

The top section of this container is fastened by means of wing nuts. This provides for easy removal for checking or replacing Radiotrons. The battery and control box cable, the loudspeaker cable and the flexible tuning cable are all held in place by means of fittings which allow their easy removal in case the box is to be removed from its mounting. The case is finished in a dull smooth black that is not easily scratched and harmonizes with the usual car finishes.

CONTROL BOX

The control box, Figure 2, contains the station selector knob, the dial scale, the volume control and the key switch. It is provided with a felt strip and mounting clamp for attaching to the steering column of the car. The dial scale is marked in channels (multiply by 10 for kilocycles) and is of the non-glare type. The switch is provided with a key, which when removed, locks the radio at the "off" position.

Figure 2—Control Box

Figure 3—Loudspeaker

Figure 4—Battery Box

LOUDSPEAKER

The loudspeaker, Figure 3, used in the automobile equipment is of the permanent magnet, dynamic type. It is housed in a smooth black finished metal container which also acts as an effective baffle. Due to the presence of the strong magnetic field, even when the set is turned off, special provision has been made to prevent metallic substances from being drawn into the air gap of the speaker and thereby cause rattles. The speaker edge and center is entirely closed, thus preventing such entry from the front. A fine gauze covering is placed over the back, thus eliminating any such matter from entering from that side. The cord outlet is provided with a rubber bushing that closes up its opening. The speaker has excellent frequency characteristics and is of extremely rugged construction.

BATTERY BOX

A special heavy steel battery box, Figure 4, is furnished as optional equipment when it is either undesirable or impossible to install the batteries behind or under the seats or in the rear compartment of the car. This box is so constructed that the batteries may be mounted and connected therein and then lifted into position beneath the car. Four carriage bolts, each provided with two lock nuts, hold it in place.

Figure 5—Antenna Plate

ANTENNA PLATE

The antenna plate, Figure 5, is provided for use when a roof antenna is not already installed in the car. It is provided with special bolts and clamps that allow easy mounting to the frame of the car. Due to the high sensitivity of this receiver, satisfactory results may be obtained with the undercar antenna except in districts where the signal intensity of all stations is extremely low. In such cases a roof antenna must be erected in accordance with the instructions given in Part I, Section 3.

R. C. A. VICTOR CO., INC.

IGNITION EQUIPMENT

Six spark plug type suppressors, one distributor type suppressor and two 0.75 mfd. capacitors. Figure 6, are provided for the suppression of ignition interference so that it does not materially affect radio reception. The details of installing this equipment are covered in Part I and varies somewhat in different cars.

Figure 6—Ignition Equipment

PART I—INSTALLATION

Due to the nature of the installation it is advisable that the RCA Victor Automobile Radiola be installed by a competent radio service man in conjunction with an automobile mechanic. The usual automobile repair shop has the necessary tools and lifts that are desirable in making the installation. If it is necessary to erect a roof antenna, this work must be done by a competent "trim" shop working under direction of the service man. However, after making several installations the service man may feel confident enough to attempt all the installation work himself, with the exception of the roof antenna. For such work the following list of equipment is provided which will be found useful when performing such work.

- 1 Pair Gas Pliers
- 1 Pair Diagonal Pliers
- 1 Pair Long Nose Pliers
- 1 Small Crescent Wrench
- 1 No. 4 Spintite Wrench
- 1 Thin Shank 6" Screw Driver
- 1 Small Screw Driver
- 1 Large Screw Driver
- 1 Pair Tin Shears
- 1 Heavy Duty Soldering Iron
- 1 Medium Soldering Iron
- Supply of Rosin Core Solder
- Supply of Acid Core Solder
- Supply of 1/2" Belden Braid
- Supply of Sheet Copper
- 1 Electric Drill with Set of Drills Up to 1/2"
- 1 Set Seat and Door Protectors
- 1 Reamer—1/4" maximum
- 1 Set Analyzer or Miscellaneous Voltmeters

(1) LOCATION AND MOUNTING OF UNITS

The proper method of installing the equipment of the RCA Victor Automobile Radiola is covered in the Installation Instructions packed with each equipment. However, as there are many different types of installations, this information will be repeated together with a discussion of its numerous variations.

RECEIVER UNIT

Location The usual location for the receiver unit is on the right side of the engine compartment bulkhead directly under the dash. Figure 7 shows a typical installation. In some cars this will have to be on the opposite side directly over the steering column, Figure 8. It is important that the space selected have at least four inches clearance directly over the receiver, otherwise it cannot be removed from the mounting bracket. Interference with other equipment under the dash, and

interference of the mounting bolts with equipment on the engine side of the bulkhead must be avoided. Figure 9A shows an installation where the receiver is in the usual location, but the loud-speaker is in the center.

Figure 7—Usual Location of Receiver

Figure 8—Receiver Over Steering Column

In some cars, the ignition coil is on the compartment side of the bulkhead or under the dash. If there is a choice of places available, the one at the greatest distance from the coil should be chosen. This is important as it reduces the ignition noise considerably.

Mounting Using the card inside of the Receiver Carton as a template, determine the proper location on the bulkhead and mark the location of the three holes with a center punch. A space at least four inches high must be left above the receiver. Extra holes are provided in the bracket to be used in case the regular holes are not satisfactory. If the bulkhead is curved, the template must be used flat and not follow the contour of the curved surface. In some cases, the receiver unit bracket must be mounted away from the bulkhead to clear obstructions. The center punch must be held perpendicular to the template when marking the holes to insure proper alignment. Next drill three 3/8 inch holes as marked. Then attach the bracket to the bulkhead by means of nuts and lockwashers furnished as shown in Figure 9.

Figure 9A—Receiver on Right with Loudspeaker in Center

Figure 9—Details of Receiver Mounting

Remove the thumb-nuts from the top, front and sides of the receiver. Remove the packing material from around the Radiotrons and make certain that they are in the proper sockets. (See Figure 10).

Press the grid contact caps firmly over the contacts on top of all RCA-236 Radiotrons. Also make sure that the tuning capacitor rotor plates are fully meshed with the stator plates so that the flexible shaft may be easily mounted. If the positive terminal of the storage battery is grounded to the frame of the car, it will be necessary to remove the bottom of the receiver and change the yellow and blue wire from its normal position on the resistor board to that indicated by the dotted line in Figure 11. Replace the bottom, the cover and thumb-nuts making sure the nuts are tight. Hang the receiver on the bracket hooks, insert the clamp screw and washer at the bottom and tighten with a screw driver.

**MODEL M-30
Auto Radio
Notes Part 3**

R. C. A. VICTOR CO., INC.

ANTENNA PLATE

Location The antenna plate, if used, should be mounted under the car and as far to the rear as possible. Also it must be as low (close to the road) as possible and still maintain the clearance of the lowest point of the car from the road.

Usually, it is mounted on the opposite side from the Muffler and exhaust pipe to prevent crowding. See Figure 13. In some cases, it is desirable to mount the plate crosswise to the car chassis. Avoid any location that will place the plate in a position that will impede the free motion of the chassis parts such as springs, drive shaft, or axles, as damage to the antenna will result.

Figure 12—Position for Control Box in Order to Make Adjustments

Mounting After determining the proper location, fasten the plates together with the screws provided. Adjust the length so that the plate is as long as possible and still fulfill the foregoing conditions. Assemble the mounting bolts onto the plate as shown in Figure 5 and fasten the clamps to the car frame. Then tighten the bolt that holds the antenna plate to the bracket and the screw and lock nut that holds the bracket to the car frame. *Too much attention to the proper tightening of these screws is impossible, as any loosening of this plate that results in one end dropping while the car is driven at high speed may result in an accident.*

Figure 13—Typical Location of Antenna Plate and Battery Box

"B" BATTERIES

Location If possible, the "B" batteries should be mounted under one of the seats or behind the back of the rear seat. In cars having a rear compartment or trunk, the batteries may be located therein.

However, if such a place is not possible, then a battery box must be used. This box can usually be mounted under the car by fastening to the floor boards. Its location should be as far from the muffler and exhaust pipe as possible, as the heat from these parts will have a detrimental effect on the life of the batteries.

LOUDSPEAKER

Location The Loudspeaker may be mounted at several locations, in most automobiles. However, the preferable location is on the bulkhead facing the rear of the car and on the opposite side from that of the receiver. If several locations are available, choose the one that gives the best acoustical results. This can easily be determined by experiment by not mounting the speaker until the rest of the equipment is in place and the receiver operating.

Mounting The instructions for mounting the receiver assembly apply equally well to the loud speaker, with the exception that the loudspeaker is mounted direct, there being no bracket provided. A template is also provided for this unit. No clearance space above the loudspeaker is required.

Figure 10—Radiotron Socket Location

CONTROL UNIT

Location The control unit is mounted on the steering column at a convenient height for the driver. Due to the large size of the steering wheel hub on some cars, this distance must be adjusted for best visibility.

Mounting Place the felt around the steering column and hold it in place by means of string or a piece of tape. Remove one screw from the clamp and place the box and clamp around the felt. Replace the screw that was removed and tighten both screws equally.

FLEXIBLE SHAFT

Location The flexible shaft is used to mechanically connect the tuning capacitor in the receiver assembly to the drive and dial in the control box. It should be placed and fastened to the car so that it connects these two points together and is clear of any foot room or instruments. On some cars a special length shaft will be required. Such flexible shafts are listed in Part IV, page 24.

Mounting Turn the Station Selector until the flat side of the shaft may be seen through the hole in the side of the unit. Insert the end of the shaft into the opening at the rear of the Control Unit making certain that it engages the end of the shaft inside of the latter. Turn the shaft until the set screw is visible and tighten the set screw against the flat side of the shaft. Thread the coupling nut of the shaft onto the Control unit.

Turn the Station Selector knob clockwise so that the dial is at the extreme counter-clockwise position. Then insert the free end of the shaft into the opening provided on the receiver, turning the Station Selector knob back and forth until the shaft meshes. Tighten the collar that holds the shaft to the receiver unit.

After completing these two operations, slowly turn the Station Selector knob to the extreme clockwise and then to the extreme counter-clockwise position. Normally, this will insure the use of the complete range of the dial. If, however, it is noticed that a slight amount of tension is present at either end of the dial, then the control unit must be turned on the steering column in the direction of the tension, while making this adjustment. Then returning it to its normal position will relieve this additional tension. Figure 12 gives the details of this latter adjustment.

Figure 11—Wiring Change for Cars Having Positive Side of +1" Battery Grounded

R. C. A. VICTOR CO., INC.

MODEL M-30
Auto Radio
Notes Part 4

Mounting Using the cover of the battery box as a template, locate the cover on the floor boards under the car and mark the boards for the center of the four mounting bolts. Drill four 3/4" holes in the floor boards. Insert the four carriage bolts in the holes from the top. Make sure the hanger bolts are in place in the cover and fasten the cover to the four bolts in the floor board. In the case of cars having metal floor boards, machine screws with spacers must be used instead of carriage bolts. Make sure that the mounting bolts do not project too far down into the box so that they will fall to clear the batteries.

After fastening the top securely in place, place the "B" batteries in the box and connect them to the receptacle as shown in Figure 14. Slip the cambic cover over the fuse and place the paper strips and plate over the terminals. Then lift the box into place, swing the hanger bolts into place and tighten both nuts securely. Care should be taken to draw up on all four nuts gradually.

For mounting both the antenna plate and the battery box, it is desirable to place the car on a "lift."

Figure 14—Battery Box Connections

IGNITION EQUIPMENT

Two .75 mfd. capacitors, six spark plug type suppressors and one distributor type suppressor are furnished to be installed in the car's ignition system so that its R. F. radiation may be reduced to a point so as not to interfere with radio reception.

One .75 mfd. capacitor is connected across the output of the generator. Remove a screw from the generator frame, usually the one holding the cut-out, insert the screw through the hole in the capacitor clamp and replace the screw. Connect the lead from the end of the capacitor to the terminal on the generator side of the cut-out switch.

The other capacitor is connected from the battery side of the ammeter to the car frame. Usually, one of the screws on the underside of the dash can be used to hold the capacitor, thereby making the ground connection. Then connect the lead to the ammeter terminal.

The spark plug type suppressors are inserted in series with each high tension lead at its point of connection to the plug. The distributor suppressor is inserted in series with the high tension lead from the coil at its point of connection to the distributor.

There are a number of variations in the installation of this ignition suppression equipment that are covered in Part II.

(2) CONNECTIONS

Loudspeaker to Receiver Insert the plug on the end of the loudspeaker cable into the two-contact receptacle on the end of the receiver. Fasten the pigtail under the self-tapping screw as shown in Figure 9

Main Cable to Receiver A long cable, from the control unit and battery box, is attached to the receiver by means of a six point female plug. Insert the plug into the receptacle on the receiver. A metal cap is fitted over two studs at the same time. Fasten the nuts over these studs securely.

Main Cables to Batteries Drill 1/2" hole in the toe boards directly below the end of the receiver unit to which connections are made. (If any holes that may be used for this purpose are already available, drilling additional holes is unnecessary). Pass the free end of the cable through the hole and thence to the "B" Battery location. Possibly other holes must also be drilled. Connect the "B" batteries to the cable as shown in Figure 15. The metal braid must be pushed back from the free end and taped so that sufficient length leads are obtained for connecting the batteries. If the battery box is used, solder the four prong plug onto the end of the cable as shown in Figure 14.

The cable should be fastened to the chassis of the car by means of the clamps or staples provided. Take up any slack by making a loop and tape securely.

Figure 15—Cable Connections to "B" Batteries

Receiver to Antenna The antenna lead should follow the shortest practical path between the receiver and the antenna. It is very desirable to avoid passing it through the engine compartment or close to the ignition coil, if mounted on the dash or compartment side of bulkhead.

If a roof antenna is used, cut the lead from the antenna as short as possible and still allow length for connection. Then cut the antenna lead and shield from the receiver to a proper length, allowing about two inches extra on the shield so that it may be slit and braided into a pigtail. Solder and tape the connections securely. Then solder the frayed part of the pigtail and either fasten or solder it securely to the car frame. The pigtail should be as short as possible and a good electrical joint made to the car frame.

Figure 16—Proper Method of Grounding Shield When Using Roof Antenna

Figure 17—Proper Method of Grounding Shield When Using Floor Antenna

If the antenna plate is used, the antenna lead and shield should be cut in the same manner as for the top antenna, except that the pigtail must be slightly longer. An eyelet terminal is provided for soldering to the end of the antenna lead so that it may be held by the screw and nut at the end of the antenna plate. The pigtail should be fastened under one of the nuts that hold the plate to its mounting bolts. Figures 16 and 17 illustrate the correct manner in making both types of connections.

Receiver to "A" Battery One side of the "A" Battery connection is made through the frame of the car. The "hot" side is made by means of a single lead that is brought out from the main cable. This lead is provided with a lug that should be fastened under the nut that holds the battery connection to the starting motor switch.

This completes the installation. All cables should be fastened securely to the car so that interference with its operation is avoided. This is especially true of those under the dash which may

**MODEL M-30
Auto Radio
Notes Part 5**

R. C. A. VICTOR CO., INC.

interfere with the driver's foot room. The switch may then be turned "on" and the receiver operated in the usual manner. Normally, starting the car engine will not introduce any objectionable noise. However, if ignition interference is present that is objectionable, then a reference to Part II will give the details for clearing up this trouble.

(3) INSTALLATION OF ROOF ANTENNA

In cars not already equipped with roof antennae, the usual installation is that of the antenna plate. Due to the high sensitivity of this receiver, entirely satisfactory results are obtained from the plate antenna in most installations. However, if the car is to be operated in a locality remote from any stations and having a general low degree of signal strength, the erection of a roof antenna is advisable. The following details cover the procedure to be used in a majority of closed cars. This work should be done by a competent "trim" man as a degree of skill, only acquired by experience, is necessary in removing and replacing the fabric top of a car.

The antenna should be composed of copper screen having a total area of at least 10 square feet. It should be located as far to the rear as possible and insulated from any metal part of the car which may ground it. In some cars having a metal rib in the center, it will be advisable to make the antenna in two pieces and use insulated wire as straps for bonding it together. All joints together with the lead-in connections should be well soldered.

USE TINNED OR BRIGHT COPPER OR BRONZ WIRE SCREEN ONLY. DO NOT USE GALVANIZED OR OXIDIZED COPPER SCREEN

DROP THE HEAD LINING FROM FRONT OF CAR SO THAT IT CAN BE FOLDED ON REAR SEAT WHILE WORKING

USE S-SCREEN OF PROPER WIDTH TO AVOID CUTTING LENGTHWISE

CUT HOLE TO CLEAR DOME LIGHT AND SOLDER EDGES OF SCREEN

STAGGER TACKS TO PERMIT LISTINGS ON HEAD LINING TO BE TACKED OVER SCREEN

TIGHTEN AND IF NECESSARY SOLDER THE DOME LIGHT CONNECTIONS

TACK DOME LIGHT WIRING TO UPPER EDGE OF BEAM SO THAT IT WILL NOT SAG OR VIBRATE

Figure 18—Details of Roof Antenna

1. First determine if there is a grounded metal screen in the roof of the car, as some cars use such a screen for the top material support. A sharp pointed instrument, connected on one side of a continuity tester, the other side being grounded, should be used. Push the point through the top lining and fish around until it comes in contact with the wire screen. If any reading is obtained, even though very small, the screen is grounded and it cannot be used for an antenna. If not, however, one corner of the head lining may be removed and a connection soldered to the screen which will make an excellent antenna.
2. If the screen is grounded or if no screen is present, it will be necessary to remove the head lining and a strip clipped from the screen several inches from all edges and from the dome light or insert a copper screen approximately of these same dimensions. If there is a possibility of the screen shifting, tack it to one of the ribs and lace the sides with cord.
3. Solder a length of shielded wire to the right front corner of the screen. Then solder or bond the shield securely to the car frame. The lead-in is then run down the right front roof

support. Usually, this can follow the path of the dome light lines. It should be noted however, that if the ignition coil is mounted on either side of the dash, it is preferable to run the lead-in down the column further from the coil.

4. Again test the antenna from the set end of the lead-in to ground for any possible shorts. If none exist then replace the head lining. Figure 18 shows a typical roof antenna installation.

(4) INSTALLATIONS ON MODEL A FORDS

The Model A Ford presents a somewhat involved problem for the installation of the RCA Victor Automobile Radiola. The reason for this is that due to the gasoline tank being part of the cowl, the usual location for the set and speaker cannot be used. Two positions for the receiver and three for the speaker are possible, each having several disadvantages.

Figure 19—Location of Units in Model A Ford

The receiver unit may be mounted in the engine compartment as shown in Figure 19, more easily than at any other location. The disadvantage of this position is that due to the high noise level present even when suppressors are used, a satisfactory installation cannot always be made. The receiver is also subject to motor fumes, water and steam used in engine cleaning and the usual atmospheric conditions.

The other alternative position for the receiver is on the right side of the driving compartment as shown in Figure 20. The dimensions for a template to be mounted to the body to hold the receiver or loudspeaker are shown in Figure 21. The interference may be successfully eliminated at this location but the position of the receiver interferes with the leg room of the person riding beside the driver.

Figure 20—Alternative Position for Receiver and Loudspeaker

Figure 21—Dimensions of Bracket for Mounting Receiver or Loudspeaker to Side of Driver's Compartment

The loudspeaker may be mounted at either side of the car, using the same template for a bracket as that shown in Figure 21, on models not having pockets at either of these locations. On such models, such as the roadster, the loudspeaker can be mounted directly behind the gear shift lever and bolted to the seat base. This location is not seriously in the way and gives good acoustical results.

The batteries may be mounted behind the rear seat in the sedan models, in the rear compartment of coupes and roadsters or in a battery box on any model.

R. C. A. VICTOR CO., INC.

PART II—SUPPRESSION OF IGNITION INTERFERENCE

In general, the use of the ignition suppressors and capacitors as described in Part I of this booklet will reduce the ignition interference to a negligible amount. However, on some installations it will be found that the noise is still present to a degree that is undesirable. In such cases, the following hints will aid the installation man in clearing up this trouble.

(1) IGNITION ADJUSTMENTS ON MOTOR

The first step in clearing up a noisy installation is to thoroughly check and remedy any defects in the ignition system of the car. By this we mean the spark plugs should be cleaned and adjusted or replaced, the breaker points replaced or adjusted and synchronized if necessary, the distributor arm filled out with solder until it makes a full even contact, and the generator commutator cleaned and its brushes adjusted or replaced. Also all wiring should be cleaned and loose connections or poor joints remedied. This work is the first step in the clean-up job and it should be done by a competent ignition expert, who has been acquainted with the need of accurately making all adjustments.

Usually, such adjustments though made on a motor that is performing efficiently, will materially reduce the ignition noise in the radio receiver.

(2) BY-PASS CAPACITORS

In some installations a re-arrangement of the connections of the by-pass capacitors will be found beneficial. For example, the by-pass capacitor connected to the battery side of the ammeter, if connected to the battery side of the ignition coil may be more effective.

In other cases using an additional capacitor at the coil, a total of three for the installation, will remedy the trouble. In all cases the generator capacitor is used, although if a clicking is heard when the cut-out makes and breaks its circuit, the pigtail should be connected to the load side rather than the generator side of the cut-out relay.

On some cars, two capacitors—one on each terminal—at the ammeter will greatly reduce the noise. This is especially true of 1932 Studebakers.

(3) IGNITION COIL

The car ignition coil, due to the high electromagnetic field surrounding it, should be at as great a distance as possible from the receiver, preferably on the opposite side of the metal bulkhead. On cars that have the ignition coil mounted on the instrument board directly over the receiver unit, it may be necessary to place it in the engine compartment. Where the switch is mounted into one end of the coil, the switch assembly must be removed from the coil and a bracket provided for mounting it. The leads from the coil should be shielded and the shield grounded. (Use Packard High Tension Cable for the high tension lead to the distributor).

Another important point is that of the primary connections. While not affecting the ignition system in its relation to the car, due to the use of auto-transformers as coils, interchanging the primary leads to a coil will sometimes materially reduce the ignition noise.

(4) ANTENNA PLATE

If grounding the antenna at its point of exit from the shield reduces or eliminates the noise, then it is feeding in through the antenna. The remedy in such a case is to place the antenna further toward the rear of the car. Also lowering it, slightly will greatly increase its signal pickup. Care must be exercised when doing this, to ascertain that the road clearance of the car is not reduced. Another important point to check is the grounding of the outer end of the antenna shield. Grounding this end of the shield to the chassis in practically all cases, materially reduces ignition noise. However, in certain cases, grounding this shield may increase the noise. In such cases the shield should be insulated with tape and left ungrounded.

(5) CABLES

Proper placing of the various shielded cables may have a bearing on the ignition noise picked up as well as contact noise caused by a variable contact between the cable shields and the car frame.

The antenna lead should follow the shortest path between the receiver unit and the antenna. If there is any possibility of the shield rubbing against any of the car frame, the cable should be taped or clamped in place. The "B" battery cable should be taut and any slack taken up by means of a loop. It should also be fastened or taped securely.

SPUCE-IN TYPE SUPPRESSOR

PLUG-IN TYPE SUPPRESSOR

BINDING POST TYPE DISTRIBUTOR USING SPARK-PLUG TYPE SUPPRESSOR.

Figure 23—Installation of Various Types of Distributor Suppressors

(6) DISTRIBUTOR SUPPRESSORS

Three different styles of distributor suppressors are used, due to the variations in the distributor head connections. These are illustrated in Figure 23. The plug-in type is supplied with this equipment and is used in the majority of cars. The spark plug type with the end flattened is used in Packard and other cars having the binding post connection. The splice-in type is used on cars that do not have a readily removable connection to the distributor head. It is spliced into the high tension lead, as close to the distributor as possible. This type may also be used on cars not having much room at the spark plugs, such as the Buick. While not furnished with regular equipment, the splice-in type suppressor is listed in Part IV.

PART III—SERVICE DATA

Service work in connection with the RCA Victor Automobile Radiola is very similar to that of the usual broadcast receiver. However, the following description of the circuit and method of making adjustments will be found helpful in locating and remedying any failure that may occur.

ELECTRICAL DESCRIPTION OF CIRCUIT

The following description of the circuit will give the service man a better understanding of the functioning of the receiver and thereby help him in his work. Figure 22 shows the schematic circuit diagram.

The first tube is the tuned R. F. stage. This is the screen Grid Radiotron, RCA-236. The control grid bias for this Radiotron is varied by means of the automatic volume control tube.

The output of the R. F. stage is coupled inductively to the grid coil of the first detector. At this point the oscillator output is also coupled inductively to the grid coil of the first detector.

MODEL M-30
Auto Radio
Notes Part 7

R. C. A. VICTOR CO., INC.

If the other adjustments have not been tampered with—the intermediate tuning capacitors—the following procedure may be used for adjusting these capacitors.

1. Loosen the receiver unit clamping screw and dismount the receiver from its mounting bracket. Do not remove any of the connections or the flexible cable.
2. Procure an R. F. oscillator giving a modulated signal at exactly 1400 K. C. and 600 K. C. Also procure a non-metallic screw driver—Stock No. 7065 — and a No. 5 Spintite socket wrench.
3. An output indicator is necessary. This should be a current-squared thermo-galvanometer substituted or connected in parallel to the loudspeaker leads.

Figure 24—Location of Radio Frequency, Oscillator and Intermediate Frequency Adjustments

4. Remove the top cover of the receiver and remove the automatic volume control tube. Also ascertain that the tuning capacitor is fully meshed when the dial reads 150.
5. Place the oscillator in operation at exactly 1400 K. C. and couple it to the antenna. Set the dial at exactly 140 and adjust the coupling between the antenna and oscillator so that the output indicator does not give an excessive reading.
6. With the socket wrench, adjust the oscillator (see Figure 24), the first detector and the R. F. line-up capacitors until a maximum deflection is obtained in the output meter.
7. Set the oscillator at 600 K. C. Tune in this signal with the receiver and adjust for a deflection in the output meter. Now adjust the 600 K. C. series capacitor, Figure 24, until maximum output is obtained. Rock the tuning capacitor back and forth while making this adjustment.
8. Change the oscillator frequency to 1400 K. C. and set the dial at 140. Again make the adjustments given under 2, 3, 4, 5 and 6.

(2) I. F. TUNING CAPACITOR ADJUSTMENTS

A single intermediate frequency amplifier stage is used in this receiver. Two transformers are used and all circuits are tuned to 175 K. C. The circuits are peaked and when alignment adjustments are made, the capacitors are adjusted for maximum output. It will be necessary to remove the chassis from its mounting bracket as is the case of the R. F. adjustments.

This is a tuned grid circuit oscillator using a Radiotron RCA-237 and having a closely coupled plate coil that gives sufficient feedback to provide stable operation. The grid circuit is so designed that by means of a correct combination of capacity and inductance a constant frequency difference between the oscillator and the tuned R. F. circuits throughout the tuning range of the receiver is obtained.

The next circuit to examine is the first detector. The circuit is tuned by means of one of the gang condensers to the frequency of the incoming signal. Radiotron RCA-236 is used in this stage. In the grid circuit is present the incoming signal and oscillator frequencies. The beat frequency —175 K.C.—appears in the plate circuit of the first detector which is accurately tuned to 175 K.C.

The next stage is that of the I. F. amplifier. A single stage is used, requiring two I. F. transformers, consisting of four tuned circuits. The plate circuit of the first detector, the grid and plate circuit of the I. F. amplifier and the grid circuit of the second detector are all tuned to 175 K.C. Radiotron RCA-236 is used in this stage and its control grid voltage is also varied by means of the automatic volume control tube.

At this point it is well to consider the action of the automatic volume control tube as it controls the R. F. and I. F. amplifiers of the receiver. The grid of the automatic volume control tube, RCA-237, is connected direct to the cathode of the second detector.

The change in the bias voltage of the second detector, due to fluctuation of the signal, is applied to the grid of the A. V. C. tube. This produces a voltage drop across a resistor in the plate circuit which constitutes the control grid bias for the R. F. and I. F. amplifier. As the value of the plate current is a direct result of the voltage applied to the grid, a greater plate current gives a greater voltage drop across the resistor in its plate circuit and therefore a higher bias on the I. F. and R. F. stage. This results in less sensitivity and vice versa. The volume control varies the bias on the grid of the volume control tube.

The second detector is of the grid-biased type, using Radiotron RCA-237. The purpose of the second detector is to extract the audio frequency component of the R. F. signal which represents the voice or musical modulations produced in the studio of the broadcasting station. The audio component is extracted and used to drive the first A. F. tubes while the R. F. current is by-passed and not further used.

The output of the second detector is coupled by means of resistance coupling to the grid of the first A. F. Radiotron RCA-237. This audio stage is used as a driver for the Class B amplifier.

The output of the first audio stage is coupled by means of transformer coupling to the grids of the Radiotrons UX-112-A used as a push-pull Class "B" power stage. This stage is so biased that normally no plate current flows. However, as the grid swings positive due to the signal voltage being applied, plate current flows which is entirely of an audio character. As there is little residual current when no signal is present, this is a very economical amplifier as well as providing a high undistorted output—2 Watts.

The entire "A" battery current drain is 2.85 Amperes and the "B" current 12 M.A. minimum and 25 M.A. average maximum.

Filament and heater current is supplied from the storage battery in the car. Plate current is supplied by means of four medium size "B" batteries. A fuse is provided in both filament and plate circuits to protect the batteries and tubes.

(1) R. F. AND OSCILLATOR ADJUSTMENTS

Four adjustable capacitors are provided for aligning the R. F. circuits and adjusting the oscillator frequency so that it will be at a 175 K. C. difference from the incoming R. F. signal throughout the tuning range of the set. Poor quality, insensitivity, and possible inoperation of the receiver may be caused by these capacitors being out of adjustment.

MODEL M-30

Notes Part 9

R. C. A. VICTOR CO., INC.

General View of Typical Installation of Automobile Radio

(7) VOLUME CONTROL

Normally, turning the volume control to the extreme counter-clockwise position will reduce the output volume of the receiver to zero. However, in event a powerful local station does not reduce to a satisfactory level, then check the following points.

- a. Automatic volume control tube. Try interchanging it with others of a similar type or replacing it with a new one.
- b. Volume control. Normally the volume control is of 50,000 ohms resistance. If for any reason it should be less, then the fixed resistor R-16 must also be reduced in value so that the proportion of 50,000 ohms to 70,000 ohms is maintained. For example—if the volume control measures 30,000 ohms, the fixed resistor should be replaced with one of 42,000 ohms. Such a replacement is much easier than a replacement of the complete volume control.

Figure 27.—Internal Connections of Cables

PART IV—REPLACEMENT PARTS

On the following pages the parts that are required for replacement use are listed. It will be noted that several parts not included in the standard equipment are also listed. There are respectively, several types of ignition suppressors and special length flexible shafts. Reference to these parts has been made in the text and on some special installations they will be required.

Portable
Chassis-Notes

R. C. A. VICTOR CO., INC.

PORTABLE
RADIOLA P-31

Permanent magnet dynamic type loudspeaker. An extra winding, shunted by a capacitor, acts as a high frequency pick-off.

See page 2-59 for the RCA Victor Portable Radiola P-31 is similar to that of other RCA Victor Super-Hit only receivers. Adjustments of the R. F. Oscillator and I. F. stage should be made in a manner similar to that described in the Service Notes on the Automobile Radiola W-30. The location of the various line-up capacitors is the same as that of the W-30.

In making line-up adjustments on the P-31, there is one important feature that affects the operation that should be remembered. That feature is the automatic volume control. Due to it being a combined A. V. C. and second detector, it cannot be removed from its socket or replaced with a dummy Radiotron.

R. F. OSCILLATOR AND I. F. ADJUSTMENTS

The R. F. Oscillator and I. F. Adjustments in Model P-31 are similar to those of the Automobile Radiola W-30. However, due to the A. V. C. tube also being the second detector, it cannot be removed while line-up adjustments are made. The proper manner in making this adjustment is as follows:

- Set the volume control of the receiver at maximum.
- Reduce the output of the external oscillator or its coupling to the receiver until a definite reduction in output meter reading is obtained. The oscillator output should again be reduced until but a slight indication on the output meter is obtained. At this low input the A. V. C. action is not sufficiently flat to interfere with the proper alignment of the various circuits.

SERVICE DATA

The plate circuit of the first detector, the grid circuit of the I. F. amplifier, the plate circuit of the I. F. amplifier and the grid circuit of the second detector are all tuned to 175 K. C.

The Radiotron RCA-234 used as the second detector is also the automatic volume control. It is a double detector, being a straight rectifier, a radio audio amplifier and a bias control automatic volume control, the signal being applied to the filament and plate of the second detector, being rectified by straight diode action.

The audio output is taken from the control grid and filament by means of capacitor C-19. The tube then operates as an Audio Amplifier, the screen grid acting as the plate. In wiring the input circuit it will be noted that the signal current flows through resistors R-7 and R-8. The drop across resistor R-8 constitutes the control grid bias for the I. F. amplifier and the 1.5 volt bias is present on these tubes being the drop across the 65,000 ohm resistor of the voltage dividing system. Also the control grid bias for the second detector is obtained from the drop across the resistors R-10 and R-11, while R-9 and R-10 in parallel constitute a grid leak for its operation as an audio amplifier, C-19 being the coupling capacitor.

The output of the detector is then coupled by means of impedance coupling to the grid of the first A. F. amplifier tube. The grid leak is in the form of a potentiometer which is the volume control, the action controlled by the audio voltage applied to the grid of the first A. F. tube. The output of this tube is then applied to the grids of the two Radiotrons RCA-230 which are connected in Push-Pull as a Class "B" amplifier. The output of this stage is then transformer coupled to the cone coil of the

RCA-VICTOR CO., INC.

MODEL M-32
Installation Notes
Part 1

INTRODUCTION

This automobile radio receiver utilizes a highly-efficient six-tube Superheterodyne circuit, a remote control unit, and a newly-designed electrodynamic loudspeaker. Because of the inherently adverse conditions to which an instrument of this type is subjected, more attention should be given to its installation than is required by a modern radio for the home. Comparable performance, however, will be obtained if these instructions are carefully followed, both with respect to installation and operation.

Three new-type Radiotrons are used: (1) the "r-f exponential pentode" RCA-39, (2) the "duo-diode triode" RCA-85, and (3) the "a-f power pentode" RCA-89. These tubes incorporate the most recent engineering features and contribute materially to the outstanding performance of this receiver. An innovation in design is found in the use of Radiotron RCA-85 which combines automatic volume control with the normal function of the second detector in a single stage.

The receiver unit is extremely compact and is enclosed by a metallic shield case. The case may be quickly detached from its mounting bolts, thereby affording maximum convenience in replacing Radiotrons or other servicing. The remote control unit

is arranged for clamping to the steering column and thus places the volume and tuning controls and the key-operated power switch readily accessible to the driver. The dial scale, located only slightly below the normal driving line of vision, is glare-proof illuminated and is calibrated to facilitate frequency selection.

High-quality reproduction is obtained by use of the new electrodynamic loudspeaker. This unit is protected against mechanical injury by enclosure in an acoustically correct and attractive metallic container equipped with tone equalizers.

Plate voltage supply for the Radiotrons is obtained from an economical "B" battery eliminator unit which is furnished as a part of the standard equipment. (A special companion model of this receiver without the eliminator and suitable for operation from external "B" batteries, is available if preferred. See Appendix I.) Equipment for the suppression of ignition interference is included with the instrument.

The use of a roof antenna in all installations is recommended. Satisfactory results in many cases, however, may be obtained with a plate-type antenna mounted beneath the floor of the car.

PART I—INSTALLATION

Equipment

A. Equipment Furnished:

1. Receiver Unit—complete with the following Radiotrons:
 - (a) Three RCA-39.
 - (b) One RCA-37.
 - (c) One RCA-85.
 - (d) One RCA-89.
2. Loudspeaker—with cable and connector plug, washer, and nuts (2).
3. "B" Battery Eliminator Unit.
4. Outfit Package—containing:
 - (a) Remote Control Unit—with bracket, felt, screws, and interconnecting cable.
 - (b) Switch Keys (2) and Fuse—packed in instruction envelope (attached to control knob of item a).
 - (c) Flexible Shafts (2) and Set Screws (6).
 - (d) Antenna Coupling Connector Sleeve.
 - (e) Mounting Brackets (4) (for receiver and "B" battery eliminator units)—complete with screws (8), bolts (8), nuts (16), washers (8), and lockwashers (8).
 - (f) Insulation Bushing (for cable entrance slot in "B" battery eliminator unit).
 - (g) Wiring Clamp (for loud-speaker cable).
 - (h) Ignition Interference Suppression Equipment:
 - 6 Sparkplug type suppressors (additional obtainable from your Dealer).
 - 1 Distributor type suppressor.
 - 2 Capacitors.
 - (i) Instruction Book

B. Additional Equipment Required:

1. Antenna—

- (a) Roof (built-in) type recommended.
- (b) Plate (sub-mounted) type—alternative. A special plate antenna complete with mounting clamps, studs, and lead-in wire is obtainable from your Dealer, if required.

Location of Units

The arrangement of units shown in Figure 1 is applicable to the majority of automobiles. In certain installations, however, such locations may be considered impractical or not in accordance with personal preference, thereby necessitating a slight change in layout. The following suggestions will be of assistance in determining the most suitable position for each unit in any given case.

Receiver and Loudspeaker—In mounting these units, the adaptability of both to bulkhead (the partition between the engine and driving compartments) suspension should be determined initially. Consideration should be given to the space available and to the possibility of interference of the units with other equipment beneath the instrument panel or of the mounting bolts with apparatus on the engine side of the bulkhead.

Remote Control Unit—The control unit should be mounted on the steering column in a position chosen to afford greatest accessibility.

MODEL M-32

Installation Notes
Part 2

RCA-VICTOR CO., INC.

Antenna—

Roof Type: Best results will be obtained by use of a roof antenna. The majority of modern automobiles (closed body types only) are already equipped with such an antenna installed at the factory, the lead-in wire from which will usually be found coiled up beneath the instrument panel. Many other earlier cars employ a piece of metallic screen—for top material support—which, if ungrounded (not in electrical contact with the metallic frame), may be readily utilized as an antenna.

NOTE—The presence of a top support screen and of grounds in that screen may be determined without removing any portion of the top fabric. Consult your Dealer as to the proper procedure for making this test.

In order to use an ungrounded support screen, one corner only of the head-lining need be removed. A shielded lead should be first soldered to the screen and then carried down the front pillar post nearest the receiver unit. Its shield covering must be soldered or bonded to the car frame prior to replacement of the head lining.

Figure 2

If the top support screen is grounded, or if no screen is present, it will be necessary to remove the entire head-lining (see Figure 2). In the former case, the screen may be insulated by removal of a strip several inches from all edges and from the dome light fixture. The possibility of subsequent shifting may be eliminated by tacking the screen to one of the ribs and by lacing the sides with cord. Where no support screen is used, a copper screen having a total area of at least ten square feet should be inserted. It should be located as far to the rear as possible and insulated from all metallic parts grounded to the frame of the car. The lead-in wire may then be attached as noted above and the head-lining replaced.

NOTE—Since a degree of skill—only acquired by experience—is necessary in removing and replacing the top fabric material, such work should be allotted to a competent "trim" man.

Plate Type: For those cases where the installation of a roof antenna is considered impractical or too costly, satisfactory reception from local or semi-

distant powerful stations may be obtained by use of the special, plate-type antenna. This unit should be clamped to the frame of the chassis as far to the rear as possible. It is adjustable in length and may be mounted either lengthwise or crosswise of the chassis which position should be selected with due regard to the prevention of overcrowding. The plate must be placed as close to the ground as possible, but not below the lowest portion of the chassis at the desired location as sufficient road clearance must be retained. It is also important to avoid any position in which the plate will impede free motion of chassis parts such as springs, drive shaft, or axles in order to prevent antenna damage.

"B" Battery Eliminator—The "B" battery eliminator may be mounted at any convenient position in the car. It is preferable, however, to place this unit near the receiver and to use bulkhead suspension when sufficient space is available. To conserve mounting space, the eliminator may be fastened to the engine side of the bulkhead but, in such cases, it is important that the unit be located as far as possible from the exhaust manifold.

Mounting the Units

Details of mounting the various units are shown in Figure 1. The following procedures are recommended:

Receiver Unit—Assemble the mounting brackets (packed in receiver carton) to the rear of the shield case by means of the machine screws furnished. Support the unit in the proper location, allowing a clearance of at least one inch above the top surface to permit ready removal for servicing. On the proposed mounting surface mark the outlines of the four key-hole shaped, bracket slots. Then drill four $\frac{5}{16}$ inch holes, coinciding with the top of the slot markings, and insert the receiver mounting bolts loosely.

The front cover of the receiver unit case (held in place by four screws) must now be removed and all packing material—inserted for protection of the Radiotrons during shipment—withdrawn. Make certain that all tubes are in position and that the control grid clips are pressed down firmly over the respective dome terminals as shown by the diagram printed on the label affixed to the top of the case. Rotate the tuning control shaft until the plates of the variable capacitor are fully meshed and adjust both shafts to positions wherein the flattened portions face upward. Then replace the front cover and tighten the cover screws in place.

NOTE—In order to further examine the radio chassis, that unit may be withdrawn from the body of the case subsequent to the removal of three screws from the lower surface. The antenna lead and the associated shield pigtail, however, must first be passed through the case side—which operation may be facilitated by detaching the small rubber bushing secured in the entrance opening.

MODEL M-32

Installation Notes

Part 4

RCA-VICTOR CO., INC.

the five leads and, when replacing the cover, secured in the cable entrance slot. The shield pigtail should be brought out through the bushing and fastened beneath the nearest cover mounting screw.

The *special* four prong plug attached to the main wiring cable must be inserted in the corresponding socket located on the left side of the receiver unit and the shield pigtail should be secured beneath a convenient screw in the lower surface of the container.

Loudspeaker to Receiver—The *standard* four-prong plug attached to the loudspeaker cable must be inserted in the remaining socket located on the left side of the receiver unit. The pigtail extending from the cable shield should be secured beneath that container screw to which the shield extension from the adjacent main wiring cable is attached.

Antenna to Receiver—The shielded lead-in wire extending from the roof or plate antenna should be cut to a length sufficient to facilitate attachment to the coupling type connector (secured to the receiver antenna lead) and to eliminate excessive slack. Refer to the detailed view of this coupling connector in Figure 1, which shows clearly the connections to be made as follows:

The small copper sleeve (packed in Outfit Package) should be slipped over the shield braid of the lead-in wire and the small internal insulated conductor passed through the female portion of the coupling type connector. Solder this conductor securely to the end of the internal eyelet. Then slip the sleeve forward to a position wherein the adjacent ends of the connector and the shield braid are covered. Finally solder the sleeve both to the coupling and to the shield and connect the assembly to that portion secured to the receiver antenna lead. Make certain that the shield pigtail extending from the antenna entrance bushing in the receiver container is securely fastened beneath one of the cover screws.

Suppression of Ignition Interference

(1) Disconnect all wires from the spark plugs. Fasten one spark plug suppressor to the top of each plug and re-attach the wires to the free ends of the suppressors.

(2) If the distributor is of the plug-in type, disconnect the center wire from the head. Plug the distributor suppressor into the distributor head and insert the wire in the free end of the suppressor.

For cap-type distributors, proceed as follows: Exchange the distributor suppressor at your Dealer's for one of a special type. Cut the wire leading from the distributor to the coil and screw the suppressor into the end attached to the distributor. Screw the other end of the wire (leading to the coil) into the opposite end of the suppressor.

(3) Clamp one of the by-pass capacitors against the generator frame. The screw holding the cut-out ordinarily may also be utilized for securing this unit. Connect the capacitor lead to the terminal on the generator side of the cut-out switch. (In some cases, interference will be reduced by connecting the capacitor lead to the opposite side of the cut-out. The most suitable position for this lead must be determined by trial.)

(4) Clamp the other by-pass capacitor securely to the instrument panel (if metallic) or to a convenient portion of the metal frame of the car, and connect the capacitor lead to the battery side of the ammeter (usually the terminal with only one lead). In certain cases, interference will be reduced by connecting the lead of this capacitor to the battery side of the ignition coil instead of to the ammeter.

(5) It may be found necessary to secure the loudspeaker cable beneath the grounding clamp (packed in Outfit Package) in order to minimize ignition interference. This clamp (as shown in Figure 1) may be attached conveniently to the left side of the receiver container.

PART II—OPERATION

The instrument should be operated as follows:

1. Insert the key in the lock on the Control Unit and turn it to the "on" position clockwise.
2. Set the Volume Control (left-hand knob) at or near the extreme clockwise position. Then turn the Station Selector (right-hand knob) in either direction until a station is heard. (Note—The dial scale is calibrated in channels to aid in station identification. Add one cipher to the scale marking to obtain the actual frequency in kilocycles.)
3. After receiving a signal, turn the Volume Control counter-clockwise until the volume is reduced to a low level. Now, re-adjust the Station Selector to the position midway be-

tween the points where the quality becomes poor or the signal disappears. *This operation insures the best quality of reproduction.*

4. Finally, advance the Volume Control (clockwise) until the desired level is obtained. Except on weak signals, the automatic volume control will maintain the volume substantially at the latter level, thereby precluding further manual adjustments. (Fading of the signal may be experienced in extreme cases, as when passing under bridges or other metallic structures, since such structures almost completely shield the antenna.)
5. When through operating, turn the key to the "off" position, counter-clockwise. The instrument is then locked by removing the key.

MODEL M-32
Battery Operated
Terminal Data

APPENDIX I—"B" BATTERY OPERATED MODEL

As noted in the Introductory section, a special instrument is available for "B" battery operation. This receiver is identical to the standard model except that the "B" Battery Eliminator Unit is omitted and a specially designed interconnecting cable is used. For such operation, four 45 volt "B" batteries are required and may be obtained from your Dealer.

The following parts are furnished as standard equipment with the battery operated receiver:

- 1 Fuse (rated 0.50 amp.)
- 2 Fuse Leads (with clips)
- 1 Fuse Insulation Sleeve
- 3 Battery Jumper Wires

Certain body types, such as coupes or sedans, afford sufficient space to permit internal mounting of the batteries. In these cases, it is necessary only to clamp the units in a manner to prevent injury or grounding through undue motion while the car is in operation. In such installations, the batteries will probably be most conveniently stacked "end to end" as shown in Figure 3.

For other installations, a special battery box for external mounting (also available from your Dealer) will probably be found necessary or desirable. This box (as shown in Figure 1) may be located at any position under the floorboards of the vehicle except near the exhaust line or where interference with free-moving parts of the chassis will be encountered. If placed in close proximity to the exhaust pipe or muffler, the heat radiation therefrom will cause rapid

Figure 3

deterioration of the batteries. The box is of suitable dimensions to accommodate the following types of "B" batteries:

- Eveready—No. 485, No. 772, No. 796
- Burgess—No. 2305, No. 2308, D-308
- General—"Flying Squad" V 30 DX

If the battery box is used, it may be mounted most conveniently by drilling the required four (4) three-eighths inch holes in the floorboard with the box cover serving as a template. Insert the four

carriage bolts from above and fasten the box cover (with the hanger bolts inserted) in position beneath the floorboard with the nuts and lockwashers provided. Place the "B" batteries in the box and make all necessary internal connections (see Figure 4). With the fibre spacers in position above the batteries and the nuts on the hanger bolts unscrewed to the ends, lift the battery box into place, swing the hanger bolts into the case brackets and tighten all nuts. Make certain that both nuts are on each bolt and locked tightly. These operations, naturally, will be facilitated by placing the car on a lift.

Figure 4

With the battery operated receiver, it will be noted that a plate circuit fuse must be employed. If the cable is to be connected directly to the batteries, the metal braid on the outside of the cable must be pushed back for a short distance in order to obtain leads of suitable length. As indicated in Figure 3, one fuse lead must be soldered to the cable wire and taped and the other connected to the end battery. The leads are equipped with clips (to permit ready replacement of the fuse) which in assembly are protected by an insulation sleeve. The end of the cable should be wrapped with tape for a short distance in order to prevent fraying and grounding to the battery terminals.

If the battery box is used, slip the rubber cover and the plug cap over the cable and solder the lead into the connection plug as indicated in Figure 4. Then fasten the cap to the plug, push the rubber cover forward and insert in the receptacle. One of the fuse leads must be connected to the proper terminal of the receptacle and the other to the end battery.

Worn out "B" batteries cause noisy and weak reception. Renew the batteries when they fail to give a reading of at least 35 volts per block as indicated by a high resistance voltmeter with the set turned "on."

APPENDIX II—SERVICE DATA

Electrical Specifications

Radiotrons Required
1 RCA-237, 3 RCA-239, 1 RCA-85, 1 RCA-89, Total—6

"A" Battery Consumption—Loudspeaker... 1.35 Amperes
Receiver... 2.15 Amperes
Converter... 3.0 Amperes

Plate Power Consumption... 35 M. A.
Undistorted Output... 1.25 Watts
Intermediate Frequency... 175 K. C.
R. F. Line-up Frequency... 1400 K. C.
Oscillator Line-Up Frequency... 1400 Only

This six tube automobile receiver gives excellent performance in respect to sensitivity, selectivity and tone quality. When used with the converter unit, operation entirely from the car battery is obtained.

Figure A—Location of Radiotrons and Line-up Capacitors

Line-up Capacitor Adjustments

The receiver must be removed from its metal case to permit correct adjustment of the line-up capacitors. After being removed, a grounded metal plate must be provided for the receiver to rest upon, otherwise the adjustments will be found to be incorrect when the assembly is returned to its metal case. After removal from its case and placing upon the metal plate, proceed as follows:

I. F. Line-up Capacitor Adjustment—The I. F. Amplifier uses two transformers, one being of the untuned variety and one having each of its windings tuned by means of two adjustable capacitors. Figure A shows the location of these capacitors.

- (a) Procure a modulated oscillator giving a signal at 175 K. C. and having its output adjustable. A non-metallic screwdriver such as Stock No. 7065 is necessary together with an output meter.
- (b) Remove the receiver from its case, place it in operation and connect the output of the oscillator between the control grid and ground of the first detector. Remove the oscillator tube and connect the output meter—preferably a thermo-galvanometer—across the voice

coil of the loudspeaker. Then with the volume control at maximum, reduce the oscillator output until a small indication is obtained. Unless this is done, the action of the A. V. C. will make it impossible to obtain correct adjustments.

- (c) Adjust the secondary and then the primary of the I. F. transformer until a maximum deflection is obtained in the output meter. This is the correct adjustment.

Figure B—Loudspeaker Wiring Diagram

R. F. Line-up Capacitor Adjustment—The R. F., 1st detector and oscillator stages are aligned at 1400 K. C. A modulated oscillator giving a signal at 1400 K. C. a socket wrench and an output meter are necessary for correctly making these adjustments.

- (a) Remove the receiver from its metal case and place on a grounded metal plate. Connect the tuning control and place in operation. Connect the output of the oscillator between antenna and ground. Connect the output meter across the voice coil of the loudspeaker.
- (b) Place the oscillator in operation at 1400 K. C. and adjust its output so that a small deflection is obtained when the receiver volume control is at maximum and the dial set at 1400. Then adjust the three line-up capacitors until a maximum deflection is obtained. This is done by means of a socket wrench.

SERVICE DATA

Information pertaining to R. F. Oscillator and I. F. adjustments together with general service data for this type receiver may be obtained from the Service Notes already issued on the RCA Radiola 80.

The beat frequency—175 K. C.—appears in the plate circuit of the first detector which is accurately tuned to 175 K. C.: The tube used as a first detector is Radiotron UY-224.

R. F. OSCILLATOR AND I. F. ADJUSTMENTS

A reference to the RCA Radiola 80 Notes will give the details for making correct R. F., I. F. and Oscillator adjustments. However, due to the use of an automatic volume control tube, its action will defeat the use of an output meter. To overcome this, a "dummy" Radiotron UY-227 (one that has one heater prong removed but is otherwise O. K.) should be substituted for the tube in the automatic volume control socket. Do not make any adjustments with this tube removed from the socket. While apparently everything functions in the normal manner, the lack of tube capacity in the circuits will cause an incorrect alignment to be made.

In the RCA Victor Radiola R-50 and R-55 the I. F. transformers are adjusted for maximum output and no attempt at band pass tuning should be made when these adjustments are made.

It will be noted on the early Models of R-50 and R-55 that a small 9 mmfd. capacitor is inserted in series with the oscillator trimming capacitor. This capacitor is not used on later models that have a slightly different dial scale. When replacing a dial scale it may therefore be necessary to short this capacitor. A failure in the capacitor may be remedied either by replacing the capacitor or the dial scale.

Models R-50, R-55, RAE-59 (1931)

PEAK FREQUENCY-175 KC

The RCA Victor RAE-59 is a Combination DeLuxe Radio and Automatic Phonograph instrument that provides a large variety of home entertainment features. The radio receiver, amplifier and loud-speaker are identical with those used in Models R-50 and 55. The automatic record changing mechanism is of simple, sturdy design and may be operated at 33 1/3 R.P.M. as well as 78 R.P.M.

Excellent home recording is a feature of this instrument, its high quality being due to the use of a two button studio microphone and a high gain amplifier. Also a much greater power output is available, due to the use of Radiotrons RCA-247 in the output stage.

SERVICE DATA

A reference to the R-50 and R-55 Service Notes will give the details of any service work necessary in conjunction with the receiver and amplifier assemblies. Figure 1 shows the schematic wiring diagram and Figure 2 the assembly wiring. A reference to the Service Notes on the RCA Victor Record changing mechanism will give any details of service work in conjunction with this unit.

MODEL RE-73
Assembly Wiring

RCA Victor Radiola Electrola RE-73 is an eight tube screen grid tuned R. F. type radio receiver combined with a standard Electrola mechanism. The receiver assembly and amplifier of this model is similar to that used in the 1930 Victor Receivers, Models R-35, R-39, and RE-57. The loudspeaker used is similar to that employed in the RCA Victor Superette R-7.

A reference to the RCA Radiola 86 Service Notes will give the details of any service work necessary in conjunction with the motor board assembly.

REPLACEMENT PARTS

Stock No.	DESCRIPTION	List Price	Stock No.	DESCRIPTION	List Price
RECEIVER ASSEMBLY—Continued					
10838	Resistor—9000 ohms—Carbon type—Package of 5	\$2.50	3082	Screw assembly—Pickup pole piece mounting screw, nut, washer—Package of 10 sets	.50
10839	Resistor—130 ohms—Carbon type—Package of 5	2.50	3101	Switch—Record-radio toggle switch with mounting nuts and escutcheon plate—Located on top of motor board	1.25
10840	Resistor—2800 ohms—Carbon type—Package of 5	2.50	3102	Receptacle—Needle receptacle	.75
10841	Resistor—1½ megohm—Carbon type—Package of 5	2.50	3158	Screw assembly—Motor mounting screw assembly—Comprising 3 screws, 3 bushings, 3 metal washers and 12 cushion washers	.80
10842	Capacitor—10 mfd. condenser—Package of 2	.60	3162	Regulator—Speed regulator with mounting screws—Comprising cam and shaft, bushing and bracket	.80
10843	Shield—Radiotron shield body with cap—Package of 1 set	.90	3163	Escutcheon—Speed regulator escutcheon with mounting screw—Package of 5	2.00
10844	Shield—Coil shield body with cap—Package of 1 set	.90	3164	Control—Record volume control with mounting washer and nut—Lens knob	1.70
10851	Panel—Radio chassis escutcheon panel—Less dial	3.00	3167	Magnet—Pickup magnet	2.60
10920	Cable—Wiring cable—Used to connect receiver to amplifier	2.75	3168	Coil—Pickup coil	.85
10948	Spring—Tuning condenser spring—Package of 5	.50	3169	Shoe—Pickup pole shoe R. H.	1.45
10949	Link—Tuning condenser link—Bakelite—Package of 5	.60	3170	Shoe—Pickup pole shoe L. H.	1.45
10969	Roller—Tuning condenser roller and shaft with eyecot screw and nut—Package of 5	.50	3249	Sleeve—Spindle sleeve complete with set screw	.50
S. P. U.					
2721	Socket—UX-245 Radiotron double socket with insulator and rivets	1.00	6067	Lever—Speed control regulator lever for motor—Comprising lever, spring, mounting bolt, nut and washer	1.60
2722	Resistor—55 ohm—Mid-tapped—Wire wound—Filament resistor	1.00	6069	Coil assembly—Located nearest governor—105-125 volts, 60 cycles—Comprising 2 current coils, 1 voltage coil, laminated core and bracket, terminal board, nuts, bolts, screws and washers—Completely assembled ready for mounting	8.40
2723	Switch—Operating switch—Toggle—With mounting nuts and washer—Package of 5	3.00	6070	Coil assembly—Located farthest from governor—105-125 volts, 60 cycles—Comprising 2 current coils, 1 voltage coil, laminated core, end bracket, terminal board, nut, bolts, screws and washers—Completely assembled ready for mounting	8.40
2757	Strip—Terminal strip—Two contact	.50	RECEIVER ASSEMBLY		
2880	Resistor—70,000 ohms—Carbon type—Package of 5	3.00	2012	Condenser—1200 MMFD. condenser	\$0.55
2963	Resistor—8,000 ohms—Carbon type—Package of 5	2.50	2546	Resistor—1 megohm—Carbon type resistor—Package of 5	3.00
7053	Resistor—715 ohms—Wire wound	.70	2746	Socket—Dial lamp socket	.50
7054	Cord—Amplifier power cord with male connector plug	1.00	2747	Cap—Contact cap—Package of 5	.50
7075	Socket—UX-280 Radiotron socket	1.80	2748	Posts—Twin binding posts with lock washers and nut—Antenna and ground	.50
7224	Cover—Fuse cover with bushing and insulator	.50	2804	Knob—Volume or station selector knob—Package of 5	2.50
10845	Transformer—A. F. transformer	14.00	2966	Resistor—28,000 ohm—Carbon type—Package of 5	2.50
10907	Fuse—3 amperes—Package of 5	1.00	2970	Resistor—¼ megohm—Carbon type—Package of 5	2.50
10908	Cover—Terminal strip cover—Package of 2	.50	7124	Socket—UY Radiotron socket	.80
10909	Condenser—Condenser bank—60 cycles	16.00	7303	Dial—Station selector dial scale—Package of 5	3.00
10910	Capacitor—Extra filter capacitor for 25 cycles	5.00	10426	Screw—Cam wheel adjusting screw—Package of 20	.50
10911	Reactor—Filter reactor	4.50	10805	Shield—Round condenser shield	.75
10912	Strip—Terminal strip—8 contacts	.70	10806	Shield—Variable condenser shield	1.50
10913	Cable—Amplifier wiring cable	2.00	10807	Shield—White enamel lamp shield	.60
10915	Transformer—Power transformer—105-125 volts—25-40 cycles	16.00	10808	Indicator—Dial indicator—Package of 5	.50
10917	Transformer—Power transformer—105-125 volts—50-60 cycles	12.00	10809	Plate—Cover plate with screw—Package of 5	.50
PHONOGRAPH PARTS					
2614	Switch—Automatic brake contact switch	1.40	10810	Roller—Cam roller—Package of 5	.50
2615	Springs—Brake springs—Set of 4 springs—Package of 2 sets	.50	10811	Condenser—Variable condenser	3.50
2620	Cushions—Pickup rubber cushion—Comprising 1 damper and 2 pivot cushions—Package of 5 sets	1.25	10812	Shaft—Cam roller shaft with washer and nuts—Package of 2	.50
2622	Coil assembly—Located nearest governor—105-125 volts, 25 cycles—Comprising 2 current coils, 1 voltage coil, laminated core, end bracket, terminal board, nuts, bolts, screws and washers—Completely assembled ready for mounting	9.00	10813	Control—Tone control with plate washers and nut	1.60
2623	Coil assembly—Located farthest from governor—105-125 volts, 25 cycles—Comprising 2 current coils, 1 voltage coil, laminated core and bracket, terminal board nuts, bolts, screws and washers—Completely assembled ready for mounting	9.00	10814	Shield—Filter coil and capacitor shield with washers and nuts—Package of 2	.60
2691	Governor—Comprising shaft with worm, brake disc, weights, springs and screws—Assembled	5.25	10815	Coil—Filter coil and capacitor with mounting screws, lock washers and nuts	\$1.50
2692	Bearings—Governor shaft bearings—One set of 2	1.35	10816	Coil—3rd R. F. coil	1.60
2693	Gear—Governor drive worm gear with set screw	1.35	10817	Coil—Link coil	1.50
2695	Bearings—Threaded thrust bearing with lock nut for end of turntable spindle	.50	10818	Condenser—Bank of two condensers—0.25 and 0.75 mfd.	1.80
2759	Box—Needle box with lid—Package of 2	.60	10819	Condenser—Bank of three condensers—Three 0.1 mfd.	1.80
2765	Screw—Pickup needle holding screw—Package of 10	.80	10820	Condenser—100 mmfd. condenser	.50
2766	Screw—Pickup cover mounting screw—Package of 10	.50	10821	Coil—Resistor board coil	.80
2767	Spring—Pickup magnet spring—Package of 10	.50	10822	Wheel—Cam wheel with spring washers, cup washer and pin	2.60
2768	Armature—Pickup armature	.50	10824	Strip—Terminal strip with insulation and rivet—Two contact	.50
2770	Plate—Pickup damper plate—Package of 5	.50	10825	Inductor—Stabilizing inductor with screw, lock washer and nut	2.20
2771	Screw—Pickup damper plate mounting screw—Package of 10	.50	10826	Control—Volume control with nut, washer and locking plate	2.50
2787	Switch—Pickup shorting switch	1.00	10828	Coil—Antenna coupling coil	1.50
2789	Cord—Motor cord—Connects motor coil and starting switch	.60	10829	Coil—1st R. F. coil	1.60
2826	Cable—Shielded cable from shorting switch to record volume control	.50	10830	Coil—2nd R. F. coil	1.60
2829	Knob—Motor board lifting knob and screw—Package of 2	\$0.50	10831	Strip—Terminal strip with link	.70
2858	Rest—Pickup rubber rest with mounting bracket—Package of 5	.50	10832	Socket—UX Radiotron single socket with insulator	.60
			10833	Strip—Terminal strip with insulation and rivets—Six contacts	.70
			10834	Clip—Tube socket clips—Package of 10	.50
			10835	Capacitor—.01 mfd.	.50
			10837	Capacitor—Bank of three 0.1 mfd. capacitors	.75

Re-aligning
Tuning Condensers

R. C. A. VICTOR CO., INC.

Under normal conditions, the occasion will seldom arise when it will be necessary to re-align the tuning condensers. Low sensitivity and selectivity and improper dial settings over certain sections of the dial for stations of known broadcast frequencies are indications that the tuning condensers are out of line.

NOTE: Improper dial settings should not be confused with improper location of selector scale.

The parts required for re-aligning consist of a modulated oscillator such as stock No.A-6004; a special aligning wrench, stock No.A-6085; and a 0-8 a-c. voltmeter.

The Victor oscillator is accurately calibrated at 550,710,1000,1300 and 1500 kilocycles. These aligning frequencies, which are the correct values used in the factory, must be employed in all cases. If a standard wavemeter is not available for calibrating, the signals from a number of reliable broadcast stations, operating on known frequencies from 550 to 1500 KC, can be used by plotting a curve of oscillator dial settings against frequencies.

Proceed to re-align the tuning condensers in the following manner:

- a. Disconnect the link (on straight radio models) across the two terminals on the base of the amplifier, and connect one side of the 0-8 volt a-c. voltmeter to the terminal nearer the UX-245 Radiotrons. Connect the other side of the a-c. voltmeter to No.3 terminal (ground) on the amplifier terminal strip or clip to any clean metallic part of the amplifier base. The meter is thus connected in the speaker output circuit, but the voice coil is out of the circuit. Silent aligning can thus be accomplished.
- b. Connect the shielded leads from the oscillator terminals to the antenna and ground terminals of the radio set, making sure that the ground wire is still connected to the radio chassis.
- c. Remove the small metal plate in the center of the cam wheel by taking out the retaining screw.
- d. Place the radio set in operation with the volume control turned to maximum.
- e. Place the oscillator in operation at 550 KC. and move the tuning lever of the Victor Radio until the oscillator signal is heard. Adjust the oscillator output volume control to obtain a reading of 2 or 3 volts on the a-c. voltmeter.
- f. It will be noted on the inside of the cam wheel that there are five groups of five screws each, and that the first screw of each group is opposite a cam roller. Using the special socket wrench No.A-6085, adjust each of the first screws until the reading on the a-c. voltmeter is a maximum. As the condensers are brought into alignment, it may be necessary to decrease the setting of the oscillator volume control in order to prevent the voltmeter from going off the scale.
- g. Move the tuning lever of the Victor Radio to 710 KC. and set the oscillator dial at this same frequency. Now adjust the second screw of each group until a maximum reading is obtained on the voltmeter.
- h. Repeat this procedure for 1000 KC., 1300 KC., and 1500 KC. The alignment is now complete. The flexible cam strip around the outer edge of the cam wheel assures perfect alignment between the aligning frequencies mentioned.
- i. Remove all oscillator and meter connections, and reconnect the link (or wire in the case of combination models).

R. C. A. VICTOR CO. INC.

SERVICE NOTES

for

RCA Victor Automatic Record
Changing Mechanism

The RCA Victor Automatic Record Changing Mechanism is used in RCA Victor Models RAE-26, RAE-59 and RAE-79. Except for the finish of exposed parts, these units are identical. This mechanism is of simple, fool-proof design and will perform efficiently with a minimum of service requirements. Features of this mechanism are: continuous playing of one side of ten 10-inch records, operation at either 33 $\frac{1}{3}$ or 78 R.P.M. for playing standard or Program Transcription records manually or automatically, a special clutch to prevent jamming in case of failure of a part and a heavy duty motor operating at synchronous speed thereby eliminating any need for regulating devices. A general view of the mechanism is shown on the cover page. Figure 1 shows the schematic wiring diagram.

The Replacement Parts for this mechanism are listed in the Service Notes on each individual instrument. The identification nomenclature given on pages 10 and 11, will be found useful in identifying parts. Where parts are identical in all models the Stock Number of each part is given in addition to its name.

Figure 1—Schematic Diagram

INSTALLATION

After unpacking the instruments in which this mechanism is used, it is imperative that certain preliminary checks be made before they are placed in operation. These checks should be performed in the order given and any adjustments found necessary must be made.

- When installing the instrument it is advisable to see that all parts are properly lubricated without excess grease or oil on any parts. This is especially important in the speed reducing unit. A lack of oil in the spindle bearings or between the sprocket and the surface upon which it rests, may be the cause of a "wow" at slow speed. Also excessive grease on the gears or on the damper pads may cause this same condition. The motor should be lubricated with light oil once every six months. Oil holes are provided at each end of the motor. Once a year the turntable and speed reducing unit should be removed and all exposed gears thoroughly cleaned and lubricated with light grease. All bearings should be lubricated with oil. Be careful not to lose the spiral spring in the end of the spindle or the washers under the turntable and speed reducing unit.

- The motor board must be level. This should be checked both ways by means of a small spirit level. Placing the cabinet legs on the same surface will usually insure the motor board being level.

- A small spring is located in the center of the turntable spindle. Be sure that this is in position before placing the turntable on the spindle. After placing the turntable on the spindle make sure that the spindle nose may be easily depressed. If it is not, then remove the turntable and turn the spring upside down or replace it with a new spring.

Figure 2—Adjusting height of tone arm

Figure 3—Adjusting elevator pad

- Examine the wire cable that is attached to the back of the tone arm. It should be seated on the small pulleys over which it passes.
- Place a Home Recording needle into the pickup as far as it will go. Then lower the pickup on the side of the turntable. The needle should extend from $\frac{1}{8}$ " to $\frac{1}{16}$ " below the top of the metal edge of the turntable. If it does not, an adjustment can be made by means of a screw located under the tone arm. Lifting the arm provides accessibility to the screw. See Figure 2.
- If when starting the automatic mechanism, the needle lowers onto the smooth outer rim of the record but fails to swing into the first groove, it may be caused by the following:
 - Cabinet not level. Check as indicated in Paragraph 1.
 - Weak tension in spring. A flat spring presses against the tone arm lever on the under side of the motor board. See Figure 17 Page 11. Bending it so as to increase its tension against the tone arm lever will cause the needle to swing into the first record groove. Be careful not to bend it too much as excessive tension will cause the needle to skip several grooves.

- After the instrument has completed one record changing operation, a ten inch record should extend about three-quarters way over each elevator pad. If this condition does not exist, an adjustment can be made by means of the screws that hold the pads in position. A pair of pliers heavily padded with cloth or other soft material should be used to hold the elevator shafts while loosening and tightening the screws. The distance from the closest part of either pad to the edge of the spindle is approximately $\frac{1}{16}$ ". Figure 3 shows the method of making this adjustment.

If any adjustments are necessary other than the foregoing, a reference to the Service Data section of this booklet should be made.

Remember That the Control Lever Can Be Changed from Automatic to Manual Only When the Mechanism is Not Changing Records

MODEL RE-73
Notes Part 2
R. C. A. VICTOR CO., INC.
SERVICE DATA

The following Service information will be found useful in making any adjustments or correction of any irregular operation that may be necessary. All the major adjustments are accessible from the rear of the cabinet. For the sake of clearness the illustrations in this text do not show the cabinet background.

No special tools required other than a small offset screw driver. (Stock No. 2930) A stand consisting of three Stock No. 77-99 will be found useful in supporting the mechanism should removal from the cabinet be required.

(1) SPEED VARIATIONS (WOW)

A variation in the speed of the turntable evidenced by distortion on long sustained notes when playing Program Transcription records may be caused by any of the following:

- (a) Improper operation. It is very important when changing the speed shift lever from 78 R.P.M. operation to 33 $\frac{1}{3}$ R.P.M. operation, to place the hand on the turntable and hold it until it is positively engaged by the driving mechanism.

Figure 4—Adjustment of damper pads

- (b) Lack of proper lubrication. It is important that excessive grease on the gear reducing mechanism be avoided and that sufficient oil is present between the ratchet and the surface upon which it rests. Also clean and oil the spindle bearing and wipe off any excess lubricant that may be on the damper pads or the drive gear upon which it rests.
- (c) Improper Adjustment of the Damper Pads. The damping pads with the necessary springs are provided to place a load on the 33 $\frac{1}{3}$ R.P.M. driving gear at all times while it is in operation. Placing such a load on the gear takes up any possible play and reduces the possibility of a "wow" during operation at the slower speed. Adjust these pads by slipping each spring to one side and bend them until they are $\frac{1}{16}$ " beyond the opposite surface upon which they rest. (See Figure 4).
- (d) Washers Not in Place. A metal washer is placed directly under the speed reducing mechanism and a leather washer directly over it, both washers being over the spindle. These washers must be in their proper position. Also if the leather washer has become hard it must be replaced.
- (e) In some cases, removing the speed reducing mechanism and turning it approximately 90° and then replacing it, may eliminate a "wow" caused by improper meshing of the gears.

(2) ADJUSTMENT OF MAGAZINE ROLLER

The magazine roller should be set in such a position that the plane of the roller is 90° to a line drawn from the center of the magazine bearing to the center of the roller. The height should be adjusted so that it will just touch the magazine when it is empty.

(3) FAILURE OF NEEDLE TO LOWER PROPERLY

Failure of the needle to lower onto the smooth outer rim of the 10-inch records when the instrument is playing automatically may be caused by:

- (a) Improper Tone Arm Setting. Loosen the set screws as shown in Figure 5. With the mechanism out of its cycle, press the locating lever at a point near the flat spring until the lever strikes the stop screw. Holding the locating lever, Figure 17, in this position, move the front portion of the trip lever, Figure 15, until the pin against which the flat spring presses, is making contact with the locating lever. Holding the two levers in this position, move the pickup arm until the needle is $\frac{1}{16}$ " from the first groove of a standard 10-inch record. Now retighten the two set screws shown in Figure 5.

Figure 5—Adjusting position of tone arm

Figure 6—Adjusting tone arm locating screw

- (b) Improper adjustment of tone arm locating screw. This adjustment, shown in Figure 6, can be used to make a substitute adjustment for that described in (a), when the mechanism is out of the cabinet. Make the adjustment so that the needle will lower exactly $\frac{1}{16}$ " from the first groove on a standard 10-inch record. Loosen the lock nut on the adjusting screw by means of a No. 4 Spintite wrench on which the shoulder has been ground sufficiently thin for clearance. Do not attempt to make this adjustment without first loosening the lock nut. Tighten the lock nut when the proper adjustment has been made.

(4) FAILURE OF NEEDLE TO LOWER ONTO RECORD SURFACE

- Failure of the needle to lower onto the record surface may be caused by:
- (a) Cable out of pulley. Examine the tone arm cable and ascertain that it is seated in the pulley.
- (b) Shielded pickup wire improperly placed. Examine the shielded lead coming out of the tone arm base and make sure that it is free from the moving parts of the mechanism.
- (c) Incorrect setting of tone arm lowering screw. Check the position of the tone arm as described in Paragraph 5, Page 4.
- (d) Turntable washer not in place. A leather washer is supplied to fit under the turntable. If this part is not in place, the turntable will be too low, and may cause the needle not to lower onto the record.
- (e) Incorrect adjustment of cable tension screw. The cable tension screw shown in Figure 7 should be so adjusted that the needle will lower smoothly onto the record without dropping. When this adjustment is obtained, the cable will be slightly loose when the needle is lowered onto a record. Loosen the lock nuts, turn the screw to the right or left as required and retighten the lock nut. Check the adjustment to make sure that the needle clears the record on the return of the tone arm. The needle should rise $\frac{1}{16}$ " from the record before any horizontal motion takes place.

(5) NEEDLE FAILS TO CLEAR RECORD AFTER PLAYING

Failure of the needle to clear the record surface on the return of the tone arm is caused by loose adjustment of the cable tension. Adjust this tension as described in Section 4, Para

R. C. A. VICTOR CO., INC.

MODEL RE-73
Notes Part 3

(6) FAILURE OF RECORD TO DEPOSIT ON TURNTABLE

Incorrect lowering of the record onto the turntable may be caused by:

Figure 7—Adjusting base screw turntable eccentric

Figure 8—Adjusting spindle height

- (a) Improper turntable spindle height. The height of the turntable spindle nose should be approximately $\frac{1}{32}$ " above the inside bottom surface of the record magazine. Adjustment of this height made by means of the screw at the bottom of the motor. (See Figure 8).
- (b) Improper setting of magazine. The horizontal swing of the magazine should be so adjusted when the mechanism is out of cycle that the outer surface at its nearest point to the nearest side of the turntable spindle is $5 \frac{1}{16}$ ". This can be done by loosening the two screws as shown in Figure 9, moving the magazine to its correct position and retightening the screws.
- (c) Improper height of record transfer lever. The small plate on top of the motor board at the left side of the turntable should be so adjusted that it will depress approximately $\frac{1}{16}$ " when the magazine swings over the turntable. When this adjustment is made correctly, the transfer lever will engage the bottom record in the magazine as the latter is swinging back into the playing position. A small adjusting screw and lock nut are provided for this adjustment. See Figure 10.
- (d) Improper Position of Record Transfer Lever. When a ten-inch record is placed so that its edge touches both pins on the record transfer lever, a line drawn from the center of the hole of the lever to the center of the record hole should pass directly over the center of the spindle. See Figure 11. The two record transfer lever mounting screws can be loosened and the lever shifted until this condition exists. Also when a record is on the turntable it should just clear this lever. Unless this adjustment is properly made the record may not center properly over the spindle.

Figure 9—Magazine turntable eccentric

Figure 10—Record transfer lever adjustment

- (e) Weak spring on turntable spindle. The spring inside the turntable spindle which holds up the spindle nose should be adjusted to align properly with the turntable spindle and the spring tension is too weak or if the spindle nose is sticking inside the spindle. Access to the spring for retensioning the coils or for replacement can be obtained by removing the turntable.

7) RECORDS DISCHARGED IMPROPERLY FROM TURNTABLE

Failure of the Record on the turntable to be removed and placed in the magazine can be caused by:

- (a) Improper horizontal adjustment of elevator pads. The elevator pads Figure 16, should be so adjusted that the inside of the pad flange is $\frac{3}{16}$ " from the nearest side of the turntable spindle. See Figure 3. Loosen the screw on top of the elevator shaft, move the pad to its correct position, holding both the pad and the elevator shaft in position and tighten the screw. Care should be observed that the ridge in the elevator shaft is not turned against the slot in the elevator shaft actuating lever so as to cut the latter. Grip the shaft with padded pliers while this adjustment is being made in order to prevent the shaft from turning. If for any reason the elevator pads have been removed, always place the one with the rubber surface toward the front of the mechanism when replacements are being made.
- (b) Improper adjustment of elevator shaft. The elevator shafts should rise to such a height as to give $\frac{1}{16}$ " clearance between the lowest surface of the elevator pad bottom and the top of the empty magazine. This adjustment can be made by means of the screw and lock nut as shown in Figure 12.

(8) FAILURE TO TRIP ON ECCENTRIC GROOVE

Failure of the mechanism to change records when the eccentric groove is reached may be caused by:

Figure 11—Method of checking transfer lever lateral adjustment

Figure 13—Adjusting height of elevator shaft

- (a) Improper setting of the latch plate. Adjust the latch plate, Figure 17, by means of a small offset screw driver such as Stock No. 2930, until it makes proper contact with the latch trip when the eccentric groove is reached.
 - (b) Weak spring on trip lever. A weak spring on the latch trip lever will be a cause of failure to trip.
- (9) INABILITY TO SET FOR MANUAL OPERATION
- The manual operation lever should set in its back position so as to free the tone arm and prevent the mechanism from tripping. This change from automatic to manual operation should be made only when the mechanism is out of its cycle, otherwise the mechanism will reject continuously. The back position of the lever should be such that the end of the lever causes the latch trip to clear the latch plate by $\frac{1}{16}$ ". An incorrect setting of the latch plate may cause the trip lever to clear the plate at one position of the tone arm, but to make contact with the plate at some other position of the tone arm. Check this point when adjusting the latch plate.
- (10) FAILURE TO STOP
- Failure of the mechanism to stop after the "off" button has been pressed, and the mechanism has completed its cycle is caused by improper setting of the secondary stop switch. See Figure 17. The switch body should be so mounted that the contacts will open $\frac{1}{16}$ " when the cycle is completed, but will close as soon as the mechanism has tripped.
- (11) CONTINUED TRIPPING OF MECHANISM
- This condition may be caused by:
- (a) Manual operation lever set for non-automatic operation during cycle.
 - (b) Improper setting of latch plate.
 - (c) Improper timing of gears and associated parts. See Section 13 for the correct method of retiming.
- (12) CLUTCH SLIPPING
- Slipping of the clutch when the mechanism is passing through the cycle causing a loud clicking noise, may be caused by:
- (a) Weak spring on pawl carrier. Remove the pawl spring Figure 17, and increase its tension by removing two or three coils.

MODEL RE-73
Notes Part 4

R. C. A. VICTOR CO., INC.

Figure 14—Motor parts

Figure 15—Bottom view of mechanism showing parts

(b) To adjust spindle suit too low. This condition will cause binding between the pawl carrier and the tone arm wheel. Refer to the slide as shown in Figure 8. The binding may be in any of the moving parts. Such binding may be in the slide, the magazine, the tone arm lever, the tone arm shaft, or the tone arm shaft collars at the left are mounted on eccentric for adjustment. The tone arm shaft may be so regulated as to cause excessive binding between the tone arm shaft and the tone arm shaft collars. Examine all of these parts carefully, and take any necessary steps to relieve the binding.

RESETTING THE MECHANISM

When the mechanism is out of adjustment, it may be necessary to reset the mechanism after replacing parts, or because of continued operation. The mechanism should be reset in its extreme forwarding position. When this setting is reached the straight side of the cam, Figure 17, will be parallel with the side of the slide. The position of the trip lever and roller at this time to see that they are approximately as shown in Figure 13. If the various parts are not in their proper relation, the mechanism should be retimed.

Figure 13—Timing position

- Loosen the set screw in the clutch wheel and lift the wheel from the turntable spindle.
- Lift the pawl carrier until it disengages from the gear.
- Lower the pawl carrier into mesh with the gears so that the trip lever is touching the end of the pawl as shown in Figure 13, when the cable lever roller is engaged in the slot on the side of the pawl carrier as shown.
- Recheck to see that the straight side of the cam is parallel with the slide.
- Replace the clutch wheel and retighten the set screw, making sure that the set screw fits into the spot on the turntable spindle.

(14) REMOVING MOTOR BOARD

Should it be necessary to remove the motor board from the mechanism for replacement of any of the parts, the following procedure should be used:

- Remove nuts and washers from the bolts which hold the motor board to the cabinet, and disconnect the pickup leads and power wiring to the mechanism. Then lift the mechanism from the cabinet.
- Loosen the two set screws and remove the magazine lever Figure 9.
- Lift out magazine.
- Unhook tone arm cable from spring.
- Loosen the two set screws in the tone arm lever.
- Remove the three small screws in the tone arm base, taking care not to lose the lock nuts.
- Disengage the tone arm lever from the tone arm shaft and carefully lift the tone arm from the motor board, bringing the tone arm lever and the shielded cable up through the tone arm base hole in the motor board.
- Remove the screw and lock nuts in the bottom of the elevator shaft.
- Lift elevator shaft from mechanism.
- Unfasten wires from motor board.
- Remove the four motor board screws which support the bottom plate.
- Carefully lift the motor board from the mechanism.

Access can now be had to all the parts on the bottom plate. The parts can be assembled in the reverse order from that given above. It will then be necessary to make various adjustments after the parts have been reassembled.

MODEL RAE-79 Schematic

PEAK FREQUENCY 175 KC

Schematic diagram of Model RAE-79

The RCA Victor Model RAE-79 is a thirteen tube, super-heterodyne radio receiver incorporated in the same cabinet with the perfected RCA Victor automatic record changing mechanism.

The following features of the instrument are:

- Automatic change Radio Chassis incorporating Super Control Radiotrons, automatic volume control, a degree of quiet operation, remote control of tuning and volume, double push-button operation, Pentode Output Radiotrons, and twin loudspeakers. The automatic record changing mechanism provides a provision for playing continuously, one side of ten 10-inch records manually. The record changer on the RAE-79 reaches a new degree of perfection through the use of a double push-button mechanism and Pentode Output Radiotrons. Such records may be made either 75 or 33 1/3 R.P.M., giving a maximum of eight minutes of home recording on a 10-inch record.

A reference to the R-50 and R-50 Service Notes covers the general service data on this type of instrument.

SERVICING DATA ON REMOTE CONTROL UNIT

The Remote Control Contactor of Model RAE-79 are adjusted at the Factory with a 115 volt A. C. input being applied to the receiver. Due to the extreme selectivity of the receiver used, it may be necessary to readjust the motor contactors when the instrument is used on extremely high or low line voltage. The following test covers these adjustments thoroughly.

This is also true on Models used at frequencies other than that specified. For example, when a 60 cycle model is used at 50 cycles, the phonograph motor must be changed and the remote control contactors completely readjusted.

The remote control feature is unique in that it not only allows control of the receiver from a distant point but also pre-selects the desired station accurately. Manual tuning, other than necessary for the original setting of the selector buttons, is therefore eliminated. Selection of any one of four stations, adjustment of the volume control, turning the receiver "on" or "off" or changing from Radio to Record may be accomplished at one or more remote points from the receiver. Operation of the tone control or home recording must be done at the receiver.

One control box and twenty-five feet of flat cable are supplied. If desired, any number of additional units may be installed or the cable lengthened to seventy-five feet.

Electrical Description of Unit

The remote control feature consists of a standard R-50 chassis with a special gang condenser; a capacitor motor coupled to the gang condenser through a series of gears; a series of drums and contactors by which the motor is started in the right direction for a given station and stopped at the right point; a special volume control geared to the motor; a relay to turn the set "on" or "off" and a remote control box by which these operations are controlled.

The motor is provided with a tapped reactor and condenser for changing the phase angle of the applied current so that operation in either direction may be secured. The motor operates at 23 volts for the station selector and 18 volts for the volume control.

Referring to Figure 1 we see the normal position of the motor armature. It will be noted that a spring holds the armature so that the gear at one end is meshed with the volume control gears. At 18 volts, the voltage used for volume control operation, the gears remain in this position and operation of the volume control is secured. When the speed of the motor is increased by operating it at 23 volts, this voltage being used when the selector buttons are pressed, the end thrust of the armature causes it to move laterally, thereby disengaging the gear at the volume control end and engaging the gear at the station selector end. See Figure 2. The spring at the end of the armature causes it to always return to the volume control position when the current is "off" at the motor. As this action takes place with the motor operating in either direction, controlling the voltage at which the motor is operated determines its function. A sixty ohm resistor is placed in each motor circuit controlling the volume to reduce the voltage from 23 to 18 volts.

The proper direction of operation and stopping of the motor for selection of a desired station is controlled by a series of drums and contactors. Figure 3 shows a schematic circuit of the motor and its adjacent circuits. The drums hold the contactors in the proper position so that when a particular selector button is depressed, the motor will turn in the right direction. When the contactor is at the point on the drum where it is half way between each contact, the motor stops. This is 180° from the hole that is used to set the drum for a particular station.

The setting of the drums is made by the pins on the front panel. These are known as the "setting buttons." The selector button is pressed and the drum is moved by the motor until the corresponding contactor is midway between the contacts. The pin will now fall in the hole in the drum if pushed in by the finger. See Figure 4. Holding the pin firmly in the hole, the desired station is then accurately tuned in by means of the manual station selector knob. After tuning, the pin is then released. As the point on the opposite side of the drum is where the diameter of the drum changes, the contactor is half way between the contacts. Pressing the selector buttons will therefore cause no movement of the motor. If another button is pressed and the drum moved, pressing the original button will always bring the drum back to the position for which it was set.

Referring to Figure 10, the schematic diagram, it will be noted that a common lead is used for the pilot lamp and the selector buttons in the remote control box. By doing this, when a selector button on the box is pressed, the current through the common lead is increased, likewise the voltage drop in the lead is increased. The result is that while the motor is running the pilot lamp becomes very dim. As soon as the motor stops, the lamp flashes bright, thus indicating that the motor has stopped and the station is tuned in. If the station is not then heard, it is necessary to press the + volume control button a little at a time until the desired output level is obtained.

Special Installations

(1) INCREASING LENGTH OF REMOTE CONTROL BOX CABLE

The cable to the remote control box supplied with the remote control models is twenty-five (25) feet in length. This is ample for most rooms as it is very rare that a person wishes to listen to a program at a greater distance from the loudspeaker.

If, however, it is desired to place the remote control box at a greater distance from the set, any twelve conductor cable, the wires of which are No. 14 or larger in size, may be used to splice onto the regular cable and increase the total length up to seventy-five (75) feet. Figure 5 shows the method recommended for adding this additional cable.

(2) INCREASING NUMBER OF REMOTE CONTROL BOXES

One remote control box is supplied as standard equipment. Any number of additional boxes may be installed if desired although only one box can be used at a time for controlling the receiver. The boxes should be connected in parallel at the terminal strip on the rear of the Radiola. Figure 11 shows such a connection.

**MODEL RAE-79
Motor Adjustment**

R. C. A. VICTOR CO., INC.

Adjustments

(1) ADJUSTMENT OF MOTOR CONTACTORS

The four station selector motor contactors located at the rear of the motor may require adjustment due to changes in the amount of friction in the entire drive assembly. Need for adjustment is evidenced by the motor failing to stop at the exact point for a particular station.

In order to make these adjustments two tools are necessary. They may be constructed, see Figure 7, or obtained as a spare part, the replacement parts section listing them. The chart on page 4 gives the procedure to be followed for making adjustments. This procedure must be repeated on each contactor that is out of adjustment.

If all contactors are out of adjustment in a similar manner, then the friction screw, see Figure 8, requires adjustment. This should be either tightened or loosened, the exact adjustment to be determined by trial. The adjustment that is correct for one contactor will be correct for all, assuming the friction screw to be at fault.

(2) REPLACING OR ADJUSTING CONTACTORS

Six contactors are used for connecting the motor so that it rotates in the proper direction. To make this adjustment or replacement, a special offset screw driver will be required unless the unit is to be removed from the base. This is shown in Figure 12.

Referring to Figure 4 we see that when the setting button is in the hole in the drum, the contactor for that particular drum is exactly half way between the contacts. The holes that hold the contactors are elongated so that they may be raised or lowered until they rest exactly half way between the contacts when the setting button is inserted in the drum hole. This is the only adjustment required of these contactors, and with the special screw driver is quite easy to make.

(3) MAKING REPLACEMENTS

The operating relay, the resistors, the motor, the gears and other small parts may be replaced. All power transformers when replaced must have the primaries so connected that the pilot light on the remote control box lights properly. If the transformers are improperly phased, the lamp will brighten instead of dim when a selector button is pressed. The drum assembly is specially fitted and assembled and any individual replacements can not be made. If trouble is experienced in this assembly, a complete replacement of the unit will be required.

SELECTOR SWITCH AND MISCELLANEOUS INFORMATION

(1) BENDIX LOUDSPEAKER SWITCH

At the end of the selector switch motor a switch is located that shorts the cone coil when the instrument is changing from one function to another.

The switch is operated by the lateral thrust of the motor wherever it goes into operation. If for any reason, noise should be heard when changing from Radio to Record or Home Recording, it may be due to this switch not functioning. Bending the lever so that it makes proper contact will remedy this condition.

(2) PRECAUTIONS WHEN MAKING RADIO RECORDING RECORDS

When making radio recording records, it is necessary that the radio volume be adjusted for its greatest undistorted output if good quality records are to be obtained. While using the maximum undistorted output it is also important that the volume control should not be advanced beyond this point, as it is possible that the maximum distorted output, if fed into the pickup long enough, will cause the pickup coil to heat and its wax to run out.

(3) SERVICE DATA ON MICROPHONE

The Microphone used on Model RAE-79 is a two-button studio type that has excellent frequency characteristics and is simple and rugged in construction. Generally, any failure in the microphone can be remedied only by replacing the unit. However, an unbalance in the buttons may be corrected by means of a small adjustment. The following procedure details the correct manner in making this adjustment. Refer to Figure 9.

(a) Remove the microphone from its shell. Be careful not to lose its supporting springs. Measure the D. C. resistance of each button. This may vary from 200 to 1000 ohms, but each button should be measured within 50% of the other.

(b) Loosen the set screw shown in Figure 9, and adjust the pressure of the cup by either increasing or decreasing its pressure against the diaphragm. Increasing the pressure reduces the resistance and decreasing it, increases the resistance of the button. Usually it is best practice to match the buttons by increasing the resistance rather than by decreasing it. Be very careful however to avoid spilling any carbon granules.

MODEL SWA-2 SW Converter
Chassis - Parts List

R. C. A. VICTOR CO., INC.

MODEL SWA-2 SHORT WAVE CONVERTER

RCA Victor Short Wave Converter SWA-2 is a t' rce tube, single control short wave unit designed to convert all short wave signals from 13.8-200 meters to a single frequency so that they may then be amplified by means of the usual broadcast receiver.

One Radiotron UY-224 is used as an R. F. Amplifying stage, one UY-224 as the detector and one UY-227 as the oscillator. Heater current for these Radiotrons is obtained from a small transformer incorporated in the unit. Plate supply is obtained from the broadcasting receiver.

A wafer connector is supplied that may be inserted under the tube socket when a receiver using a UX-280 rectifier and a filter in the negative side of the line is used. Under these conditions—most modern receivers are so designed that this is true—the plate supply to the converter is obtained through the contact on the wafer connector to the UX-280 filament. On receivers where this condition does not exist, but where Pentode output tubes are used, the wafer connector can be used to make connection to the screen grid of the Pentode. On receivers where neither condition exist any connection that gives a filtered D. C. output of from 180 to 260 volts between the contact and ground will be suitable.

Due to the SWA-2 being identical with the converter chassis used in the RO-23, reference to the RO-23 Service Notes should be made for data pertaining to Service work.

MODEL 2-25
Portable
Victrola

RCA Victor Portable Victrola Model 2-25

The RCA Victor Portable Victrola Model 2-25 is a small portable type reproducing instrument built into a metal cabinet resembling a small suitcase. Excellent quality, high output and good mechanical construction are features of this instrument.

LUBRICATION

Premature wear, noisy operation and failure of parts are direct results of failure to clean and lubricate the motor at necessary intervals. The various bearings and gears of the motor should be cleaned and lubricated at least once every six months. In addition to the regular lubrication, all motor parts should be covered with a light film of oil to prevent rusting. Use only RCA Victor Motor Oil and Motor Grease when lubricating this instrument.

Initial Operation. When the instrument is first played, wind the motor and allow it to run down completely several times. This insures a complete distribution of lubricant within the spring barrel. Maximum run is dependent on this point.

The speed of the motor should be adjusted so that the turntable revolves at 78 R. P. M. This can be checked by means of a Stroboscope Disc in conjunction with a source of A. C. illumination of proper frequency for the disc used or by counting the revolutions. In both cases a record must be playing in the normal manner when the check is made.

Figure 1—Lubrication Diagram of Model 2-25

Motor. Figure 1 shows a view of the motor with the top plate removed. Before lubricating the parts shown in this illustration, a thorough cleaning with carbon tetrachloride (Carbona) or gasoline is necessary. If necessary disassemble the entire motor for such cleaning.

Tone Arm. The joint between the taper tube and the sound chamber must be free to swing easily without play and be sealed with grease. This bearing is accessible when the three mounting screws are removed. Failure to seal this joint will result in poor quality. Unnecessary friction will cause undue record wear.

MOTOR

The motor used in Model 2-25 is of simple design and will give excellent performance. If kept clean and properly lubricated, little service attention will be required. The

following points may prove useful when it is necessary to effect repairs. *Before doing any work on the motor the machine must be allowed to run down completely.*

Removing Motor from Cabinet. To remove the motor from the cabinet proceed as follows:

- (a) Unscrew the spindle cap and remove the turntable.
- (b) Remove the four machine screws that hold the motor in place. The motor may then be removed through the hole in the motor board.

Changing Motor Springs. Should a spring break and require replacement the best method to make a repair is to replace the entire spring barrel. While the cost of the spring barrel is greater than that of the spring alone, the saving in labor will usually justify such replacement. Unless the serviceman is experienced in handling springs of this type, the following directions should be followed carefully:

- (a) Disassemble the motor and remove the spring barrel. Remove the winding gear.
- (b) Place the gear flat on a piece of metal and file off the ends of the six rivets. Remove the rivets and gear.
- (c) Place the palm of the right hand over the closed end of the barrel, making sure that the fingers do not protrude beyond the open side. Firmly hold the barrel, open side downward over a large can or barrel. With the left hand pull the center turns of the spring out. As soon as the spring starts, pull the left hand clear of the can holding the spring barrel firmly until the spring is entirely clear.

(d) A new coiled spring may prove extremely dangerous if not properly handled. Read these instructions and work very carefully especially if not experienced in work of this kind. The new spring is furnished coiled and with a heavy wire clamp holding the spring tightly wound. Pull out about one foot of the spring. Then with the spring flat on a table gently tap the ring until it comes to the edge. Do not push the clamp so close to the edge that it will not hold the spring.

Place the hook end of the spring over the barrel hook. Wind the exposed end into the barrel and then insert the entire spring in the barrel allowing the clamp to be on the outer edge. Place a block over the entire spring and force the spring into the barrel thereby releasing the clamp.

(f) Place a tablespoonful of spring lubricant between the spring leaves and in the center of the spring.

(g) Place the gear in position and rivet it with six rivets to the spring barrel. Use a small punch for flattening the ends of the rivets. Place the gear on a flat surface while re-riveting the barrel to it.

(h) Reassemble the motor in the reverse manner of that used to dismantle it.

Winding Shaft Binding. A heavy jar may cause the motor to shift slightly on the motor board and produce binding of the winding shaft against the motor board. Loosening the motor mounting screws and shifting the motor to its proper position will correct this condition.

The RCA Victor Portable Victrola Model 2-65 is a small portable type instrument built into a cabinet resembling a small suitcase. Excellent quality, high output and good mechanical construction are features of this instrument.

LUBRICATION

Premature wear, noisy operation and failure of parts are direct results of failure to clean and lubricate the motor at necessary intervals. The various bearings and gears of the motor should be cleaned and lubricated at least once every six months. In addition to the regular lubrication, all parts should be covered with a light film of oil to prevent rusting. Use only RCA Victor Motor Oil and Motor Grease when lubricating this instrument.

Initial Operation. When the instrument is first played, wind the motor and allow it to run down completely several times. This insures a complete distribution of lubricant within the spring barrel. Maximum run is dependent on this point.

The speed of the motor should be adjusted so that the turntable revolves at 78 R.P.M. This can be checked by means of a Stroboscope Disc in conjunction with a source of A.C. illumination of proper frequency for the disc used or by counting the revolutions. In both cases a Record must be playing in the normal manner when the check is made.

Motor. Figure 1 shows a view of the motor with the top plate removed. Before lubricating the parts shown in this illustration, a thorough cleaning with carbon tetra-chloride (Carbena) or gasoline is necessary. If necessary disassemble the entire motor for such cleaning.

Tone Arm. The joint between the goose neck and tone arm and that between the tone arm and sound chamber must be free to swing easily without play and be sealed with grease. The goose neck is detached or adjusted by means of two collars that hold it in place. The bearing between the tone arm and sound box is accessible when the swivel and three mounting screws are removed. Failure to seal these joints will result in poor quality. Unnecessary friction at either of these points will cause undue record wear.

Figure 1—Lubrication Diagram of Model 2-65

AUTOMATIC STOP MECHANISM

The Automatic Stop Mechanism is simple of design and effective in operation. Figure 2 shows its principal parts.

Failure to Start. Should pulling the tone arm to the right and then placing the sound box on the record fail to start the motor, it may be due to:

(a) Improper location of base plate. Loosen the screws A, B, and C and shift position of mechanism counter-clockwise until proper operation is secured.

(b) Worn or rounded surfaces at point D. Square these points with a small file.

(c) Insufficient tension at spring E. Remove a few turns or replace spring.

Failure to Trip. Should the mechanism fail to stop the motor at the end of a Victor record having the eccentric groove, check the following:

(a) Improperly adjusted base plate. Loosen screws A, B, and C and shift the mechanism clockwise until proper operation is obtained.

(b) Loose or improperly adjusted latch plate.

(c) Insufficient tension at spring F. Remove several turns or replace spring.

Tripping during Operation. Premature tripping during the operation of a record may be caused by:

(a) Binding at bearing G. Clean and lubricate this bearing.

(b) Insufficient bite at point D. Loosen the screws A, B, and C and adjust the base plate so that a larger bite is obtained at point D.

MOTOR

The motor used in Model 2-65 is of simple design and will give excellent performance. If kept clean and properly lubricated, little service attention will be required. The following points may prove useful when it is necessary to effect repairs.

Removing Motor from Cabinet. To remove the motor from the cabinet proceed as follows:

(a) Unscrew the spindle cap and remove the turntable.

(b) Remove the eight machine screws that hold the motor board in place. The sound deflector is also removed.

(c) Remove the three motor mounting screws, together with the one holding the speed regulator lever. Remove this lever. The motor board may now be turned over and the motor pulled clear and placed in a position convenient for work. The various parts are

easy of access and adjustments or replacements are simple to make.

Changing Motor Springs. Should a spring break and require replacement the best method to make a repair is to replace the entire spring barrel. While the cost of the spring barrel is greater than that of the spring alone, the saving in labor will usually justify such replacement. Unless the serviceman is experienced in handling springs of this type, the following directions should be followed carefully:

(a) Disassemble the motor and remove the spring barrel. Remove the winding gear.

(b) Place the gear flat on a piece of metal and file off the ends of the six rivets. Remove the rivets and gear.

(c) Place the palm of the right hand over the closed end of the barrel, making sure that the fingers do not protrude beyond the open side. Firmly hold the barrel, open side downward over a large can or barrel. With the left hand pull the

Figure 2—Automatic Stop Mechanism

center turns of the spring out. As soon as the spring starts, pull the left hand clear of the can holding the spring barrel firmly until the spring is entirely clear.

(d) The new spring is furnished coiled and with a heavy wire clamp. Hit the spring flat on a table thereby driving the clamp to one edge of the spring. Grasp the exposed part of the spring firmly with the right hand and pull the clamp off with the left hand. Allow the spring to gradually release its tension in the right hand and then unwind it completely.

(e) Place the hooked end of the spring over the barrel hook and wind the spring into the barrel toward the center. Be careful to push each turn completely inside the barrel before winding on the next turn.

(f) Place a tablespoonful of spring lubricant between the spring leaves and in the center of the spring.

(g) Place the gear in position and rivet it with six rivets to the spring barrel. Use a small punch for flattening the ends of the rivets. Place the gear on a flat surface while re-riveting the barrel to it.

(h) Reassemble the motor in the reverse manner of that used to disassemble it.

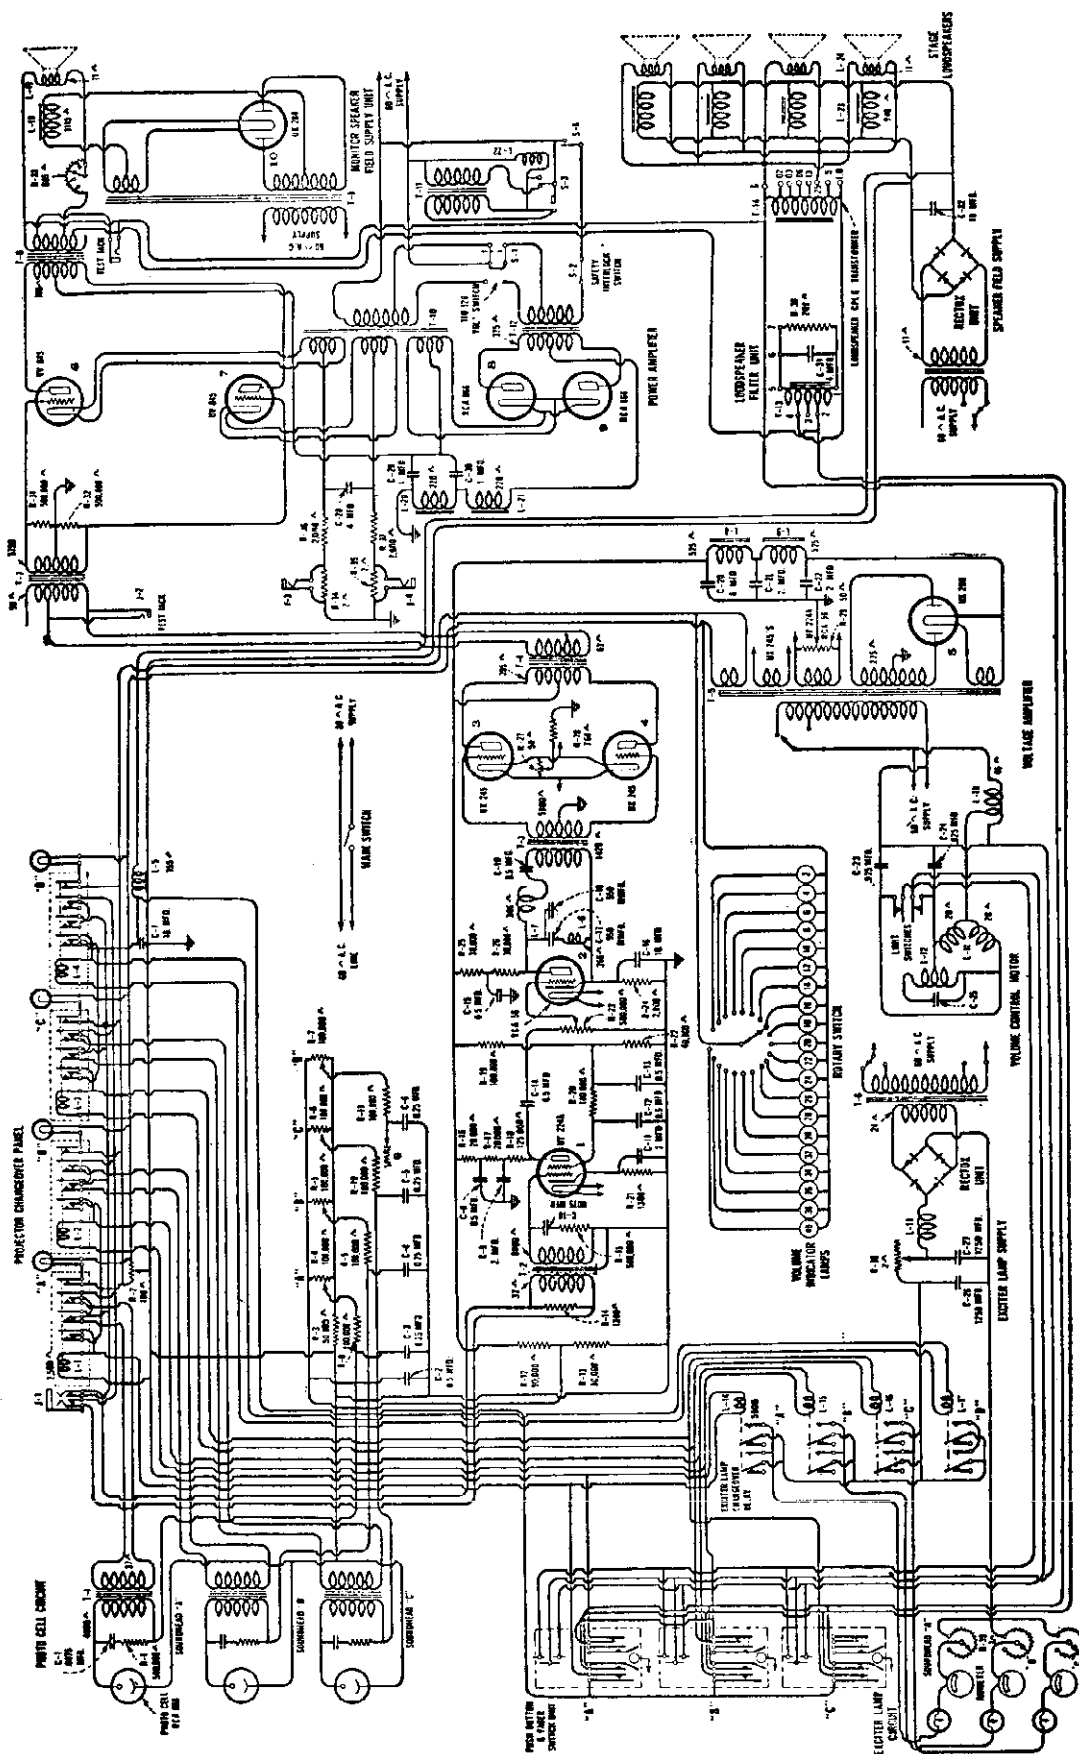

Winding Shaft Binding. A heavy jar may cause the motor to shift slightly on the motor board and produce binding of the winding shaft against the motor board. Loosening the motor mounting screws and shifting the motor to its proper position will correct this condition.

(2) RADIOTRON SOCKET VOLTAGES

The following voltages taken at each Radiotron socket with the amplifier in operating condition should prove of value when checking with test sets such as the Photophone K.R.-13 Multitester or the Weston Model 547, Type 3, or other giving similar readings. The plate currents shown are not necessarily accurate for each tube, as the cable in the test set will cause some circuits to oscillate, due to its added capacity. Small variations of voltages will be caused by different tubes and line voltages. Therefore, the following values must be taken as approximately those that will be found under varying conditions. The numbers in column 1 indicate the tube socket numbers shown in Figure 21.

Figure 21—Radiotron Socket Layout

Due to the voltage drop in the plate resistors caused by the current consumed in the test voltmeter, the screen grid and plate voltage readings obtained for the Radiotrons UY-224-A and RCA-56 are not true values.

To measure the plate current of the Radiotrons UY-845 a low range voltmeter or a millivoltmeter is required. The meter should be connected to a Yaxley No. 75 phone plug or a similar plug and the plug inserted into the plate current metering jacks on the base of the power amplifier.

Two millivolts read on the test meter equals one milliampere of plate current.

Set the LOCAL - DISTANCE switch on DISTANCE and the wave-changing switch on LOW. With the 180 K.C. signal attenuated so low as to be just audible adjust the four controlling trimmers of the I.F. for maximum signal.
The two I.F. transformers and their trimmers are located in the upper right shield cans at the extreme left of the chassis.
To make the dial run true to its Kilocycle markings, set the dial at or near 800 K.C. using an oscillator or a Broadcasting Station of known frequency. By tuning to an oscillator or station at or near 560 K.C. the dial may now be made to "track" by adjusting the radio set's oscillator series padding condenser. This is located next to the oscillator tube socket beneath the chassis but must be adjusted thru the hole in the chassis between the oscillator tube and the variable tuning condenser.

Control grid volts of the R.F. tubes and detector are measured from Cathode to Ground. 245 Grid volts Filament to Ground.

CIRCUIT DATA - The 25 cycle models are identical electrically with the 60 cycle models except for power transformer, filter condensers and omission of hum balance potentiometer. Characteristics are the same as the 60 cycle models. Voltages are slightly lower and there is a difference in the arrangement of parts. The volume control used on these receivers operates by varying the coupling between the primary and secondary on the antenna and R.F. stages. This variation in coupling is effected by moving the primary coils. The antenna and R.F. primaries are also moved by the rotation of the tuning condenser to maintain uniform sensitivity over the broadcast band. The detector primary is not moved to control volume but is moved by rotation of the tuning condenser. This system of volume control does not change the voltages or currents in the tubes. The new variable-mu, screen grid tube, -35, may be used interchangeably with the -24 in the R.F. stages only.

OSCILLATION - Oscillation in receivers employing the variable coupling volume control may be caused by (A) Leads to the movable primary coils too close together, causing interstage coupling. The pairs of leads should be spaced at least 1-1/4 inches apart throughout their length. (B) Movable primaries in wrong position. When the dial is set at 55, and the volume control set at maximum, the primaries should be at the position of maximum coupling. The U-brackets carrying the coils should have about 1/32 clearance from the plate which supports the RF coils. When the volume control is left at maximum and the dial turned to move the condenser to the higher frequency settings, the coils should remain approximately in line, the RF coils moving out slightly more than the detector primary. Adjustment may be made by moving stop collar on rear end of volume control shaft.

Speaker Field Voltage	100 Volts								
Total Plate Current	.075 amp.								

Note: Control grid volts are measured from cathode to ground or cathode to heater. 247 grid voltage from grid to ground or filament.

NOTE: In this set the hum across the field coil is used to buck out hum set up in the tube circuits. Causes of hum can be traced to defective detector or output tubes. (Interchange output tubes) Shorted condenser or open resistors in hum filter circuit. The hum filter circuit consists of a 2000 ohm resistor and a 0.5 condenser in the grid bias resistor circuit. This connects from the cathode of the detector to the negative side of the speaker field. Other causes of hum are Reversed speaker field, open or shorted condensers in detector circuit, open or grounded 20 ohm center tamped resistor, defective tone control, defective speaker or a defective electrolytic condenser.

Speaker Field Voltage	-	110									
Total Plate Current	-	80 ma.									

Note: All voltages measured with a 1000 ohm per volt meter, 250 volt scale, with volume level control at maximum. 247 output grid voltages were measured from filament to ground, and translator grid from cathode to ground. Grid voltages on the RF and IF will be variable when the set is operating. AVC plate voltages will be the grid voltages on RF, IF and translator tubes.

Notes - Causes of no signals can be traced to some of the following reasons. Grid slips shorted to tops of tube shields. Open or shorted condensers. Unsoldered leads. Solder under tube socket terminals. Defective tubes. Oscillator not working. Open image suppressor coil. Defective speaker or shorted tone control connection. Poor quality can be traced to defective output or detector tubes. Set not tuned properly. A poor 235 in the IF, RF or translator sockets will give poor quality and unsatisfactory volume control. Shorted or open grid

coupling condenser in the audio circuit, or open resistors in the audio circuits will also contribute to poor quality. Oscillation can be traced to defective tubes, grid leads of detector and IF too close, or an open condenser in the plate circuit of the translator.

VOLTAGE TABLE

Never check voltages until all tubes are fully warmed up to proper operating condition. The voltage table given below is taken at 115 volts line with a Model 547 Weston set checker. It must be remembered that the voltage readings taken vary directly as the line voltage and also with the accuracy of the meters used. A variation of 10% plus or minus is permissible.

<u>TUBE VOLTAGES</u>		115 V. Line Volume Control Full On				
Type of Tube	Position of Tube	Filament Volts	B Volts	C Volts	NORMAL PLATE M.A.	Screen Volts
227	Oscillator	2.4	62.5		4.75	
235	Radio Frequency	2.4	240	2.15	2.75	27
224	1st Detector	2.4	230	4.35	.5	65
235	Intermediate	2.4	237	2.15	2.75	72
224	2nd Detector	2.4	100*	2.1*	2.5	35*
247	Pentode	2.4	250	16.5**	32.5	250
280	Rectifier	4.95			27 ea. plate	

*These readings are only comparative and are not true voltages applied. The volt meter, when the readings are taken at these points, is in series with a very high resistance.

** To read the 247 bias, read between H.K. speaker socket and ground.

ALIGNMENT OF RECEIVER:

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need re-tracking. Only when an intermediate coil has become defective due either to an open or burned out winding, should it be necessary to re-adjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the top of the intermediate shield can. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then re-check the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away, the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1295, 880, 650 and 550 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are especially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

ANTENNA:

Satisfactory radio reception is largely dependent upon a proper antenna and ground installation. It is not possible to prescribe any definite form of antenna construction, as the most satisfactory aerial for any particular installation will vary in different locations, depending largely upon local structural details and sources of interference. Because of the enormous amplification obtained from the superheterodyne receiver, a large antenna is not desirable nor necessary. An antenna of from 15 to 35 feet, including lead-in and ground, will in most installations be ample. In congested districts an excessively long antenna will result in apparent loss of tone quality and increased hum. In isolated communities where distant daylight reception is desired, the length of the antenna may be increased so as to obtain satisfactory reception.

While in most installations A.C. receivers apparently work almost as well without a ground as they do with one, in no case should an installation be made where the receiver is not connected to a good ground. Water pipes and steam radiators generally make satisfactory grounds. The ground lead should be connected by means of an approved ground clamp or soldered to a section of the pipe that has been thoroughly cleaned. If neither are available a 6 ft. iron pipe driven in the ground, preferably in a position where the soil is moist, will be satisfactory.

MODEL 109

SENTINEL RADIO CORP.

TUBES:
 This Receiver utilizes the following tubes:
 Two (2) Type 224
 Two (2) Type 225 or 221
 One (1) Type 227
 Two (2) Type 229 or P.Z.
 One (1) Type 234
 One (1) Type 247
 One (1) Type 280

PEAK FREQUENCY = 175 K.C.

Sentinel Model-109.
 HIGH VARIABLE-INDUCTIVE
 ELECTRO-TONE SUPERHETERODYNE

VOLTAGE TABLE
 Never check voltages until all tubes are fully warmed up to proper operating condition. The voltage table given below is taken at 115 volts line with a Model 547 section set absorber. It must be remembered that the voltage readings taken vary directly as the line voltage and also with the accuracy of the meters used. A variation of 10% plus or minus is permissible.

Type of Tube	Position of Tube	Filament Volts	B Volts	B+ Volts	Normal Plate Grids	Screen Plate
227	Oscillator	1.4	21.5	21.5	4.75	27
224	Radio Frequency	2.4	4.35	4.35	2.75	65
228	1st Detector	2.4	2.15	2.15	2.75	72
229	Intermediate	2.4	2.1	2.1	2.5	25*
234	2nd Detector	2.4	10.0*	10.0*	22.5	250
247	Pentode	2.4	16.8**	16.8**	22.5	250
247	Pentode	2.4	20	20	22.5	250
280	Rectifier	4.56	115 V. Line	115 V. Line	47.5	250

*To read the 247 bias, read between H.K. speaker socket and ground.
 **To read the 247 bias, read between H.K. speaker socket and ground.

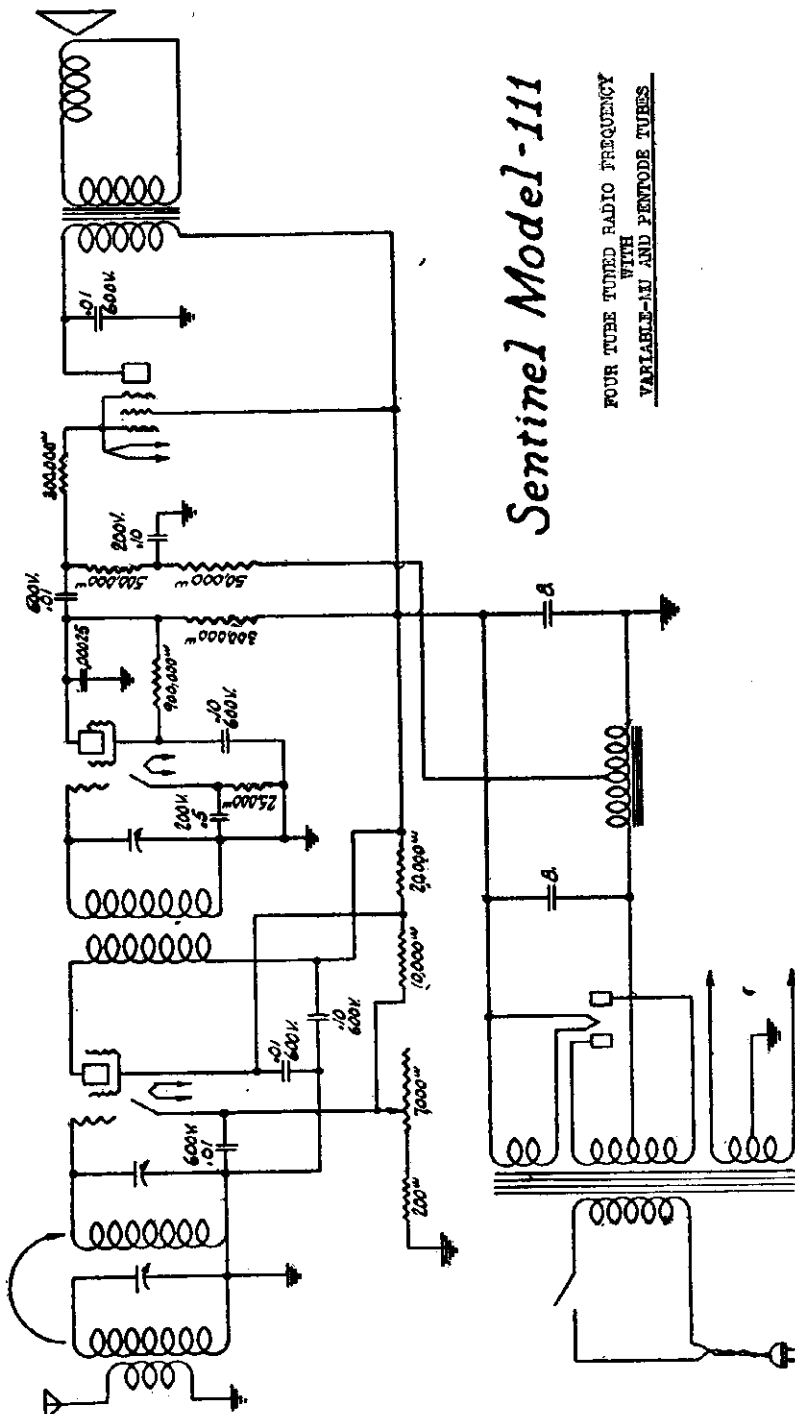

ELECTRO DYNAMIC SPEAKER:
 The electro dynamic speaker has a tapped field winding - one section of which is 565 ohms and is utilized as the second choke in the filter circuit. The other section, which is 175 ohms, is used to obtain the proper bias for the 247 tubes, as well as acting as an additional filter choke.

VOLTAGE REGULATOR TUBE:
 Shipped with each receiver is a fuse plug containing a 4 ampere fuse and one spare 4 ampere fuse. Frequent and continued burning out of the fuse is an indication that either there is a defective tube, or some part of the receiver is defective, and these possible sources of trouble should be carefully checked if this condition exists. In districts where the line voltage is excessively high or low or fluctuating, the fuse plug may be substituted by a line voltage regulator tube which will maintain the voltage applied to the primary more constant. Either an Aerovite #10-10 or Duresite #101 may be used.

MODEL 111

Sentinel Model-111

FOUR TUBE TUNED RADIO FREQUENCY WITH VARIABLE-MU AND PENTODE TUBES

ALIGNMENT OF RECEIVER:

To align receiver it is recommended that an oscillator and output meter be used, as much better results can be obtained than by aligning on a broadcast signal. However, in either case the procedure is the same. To align the variable condensers connect the high side of the test oscillator to the antenna lead and the low side of the oscillator to the ground lead and tune the oscillator to 1500 kilocycles, adjusting the output of the oscillator so that a convenient reading is obtained on the output meter. If during the alignment the meter goes off scale, adjust the output of the test oscillator or reduce the output by adjusting the receiver volume control. It is important that the receiver be tuned to minimum capacity stop. Then track the variable condensers at this point by adjusting the trimmer condensers, which are mounted on top of the variable condensers, to maximum reading on the output meter in the following order: Antenna, Coupling Stage and Radio Frequency Stage. The variable condenser sections are: (Antenna, Coupling Stage, and Radio Frequency Stage looking at the receiver from the front, reading toward the back.)

After the variable condensers are properly aligned at 1500 kilocycles by adjusting the trimmer condensers, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency, making sure that the receiver is tuned exactly in resonance with the incoming signal, and check alignment of the condensers at this point by bending the end plate of the rotors on the antenna, coupling stage and radio frequency stage in the order named, noting the change in reading on the output meter. If when the plates are bent in the point of the variable condenser and the end plate should be permanently bent; or if when the end plate is bent away the reading is increased, that section requires less capacity at that particular point, and the end plate should be permanently bent away from the stator. Each section of the variable condenser should be checked in this manner at 1295, 830, 750 and 550 kilocycles. These frequencies have been chosen so as to take advantage of the slots in the end plates of the variable condenser.

Model 111

ELECTRO DYNAMIC SPEAKER:

The electro dynamic speaker has a tapped winding, one section of which is 1320 ohms and the other section 300 ohms is used to obtain the proper bias for the 247 tube. The field winding is used as the filter choke.

Tube Voltage

235	Radio Frequency	2.4	250	2.5	4		90
224	Detector	2.4	65*	3.5*	4		37.5*
247	Output	2.4	230	16.5*	35	250	
250	Rectifier	5.			30 M.A.		

115 V. Line Volume Control Full On

*These readings are only comparative and are not true voltages applied. The volt meter, when the readings are taken at these points, is in series with a very high resistance.

SENTINEL RADIO CORP.

MODEL 114
Voltage- Data**ALIGNMENT OF RECEIVER:**

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need retracking. Only when an intermediate coil has become defective due to an open or burned out winding, should it be necessary to readjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the bottom of the chassis. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then recheck the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1295, 880, 650 and 550 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are especially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

Schematic Data

MODEL 716 Tuner & 683 Amplifier and Power Supply

There are two mounting holes left open on the tuner chassis for mounting the variable bass, and the high tone controls that are connected to flexible leads on the 683 amplifier.

Looking at the rear of the tuner, the antenna and ground posts are mounted on the top left of the chassis. On the right rear of the chassis is the output post marked "plate". This is connected to the input post on the 683 amplifier.

In the rear center of the chassis is a four terminal strip, color coded as follows: Red, Blue, Black, Black. A coded cable is furnished with the tuner for connecting this terminal strip to the 683 or similar amplifier.

The color code reads as follows: Red-B positive 240 volts, Blue-B negative or ground, Black, Black - 2½ volt heater or filament supply. The cable supplied with the tuner contains two heavy duty filament lead wires colored Green-Black and connect to the two Black terminals on this strip.

There are two sets of four terminal lugs on the back of the amplifier. Looking at the rear of the amplifier the set on the right are connections for the SM 855B speaker or similar type of speaker. Cable is furnished with the amplifier. This terminal strip is color coded as follows: red, black, blue, blue. The two blue leads connect to the speaker voice coil, the red and The SM 855B

SIMPLEX RADIO CO.

MODEL N D.C.
MODEL R A.C.

SHORT WAVE: Left hand knob when clear to the left is on Short Wave. A one-quarter inch movement to the right and it is on regular broadcast. Beyond this point it functions as a tone control.

PHONOGRAPH: Use a single pole switch mounted as near as possible to detector socket, connect in series with lead from ground end of grid coil of detector tube. Solder phonograph pickup leads to switch terminals.

Models N-DC

Model R (1932)

CAUTION: Do not attempt to operate on current other than that noted on instrument. Reverse attachment plug if set does not start operating in a few seconds after being turned on.

BALANCING: The intermediate stage is carefully phased and sealed to 175 K. G. and should not be tampered with.

PHONOGRAPH: Use a single pole switch mounted as near as possible to the second detector socket, connect in series with lead from ground end of the grid coil of second detector tube. Solder phonograph pick-up leads to switch terminals

SIMPLEX RADIO CO.

Schematic

MODEL P

CAUTION: DO NOT ATTEMPT TO OPERATE ON CURRENT OTHER THAN THAT NOTED ON INSTRUMENT.

INSTALLATION: "Ant" lead may be fed from "B'LT-IN-ANT" lead, indoor or out door aerial, radiator, bed springs or any large metal object, if desired. **BALANCING:** The intermediate stage is carefully phased and sealed to 175 K. C. and should not be tampered with.

TO RECEIVE ON 1500 TO 4000 KILO-CYCLES: Turn tone control knob to end of range until switch throws to 4000 k. c. band. To throw back to broadcast band turn tone control in opposite direction until switch throws.

PHONOGRAPH: Use a single pole switch mounted as near as possible to second detector socket, connect in series with lead from ground end of switch terminals

MODEL Q

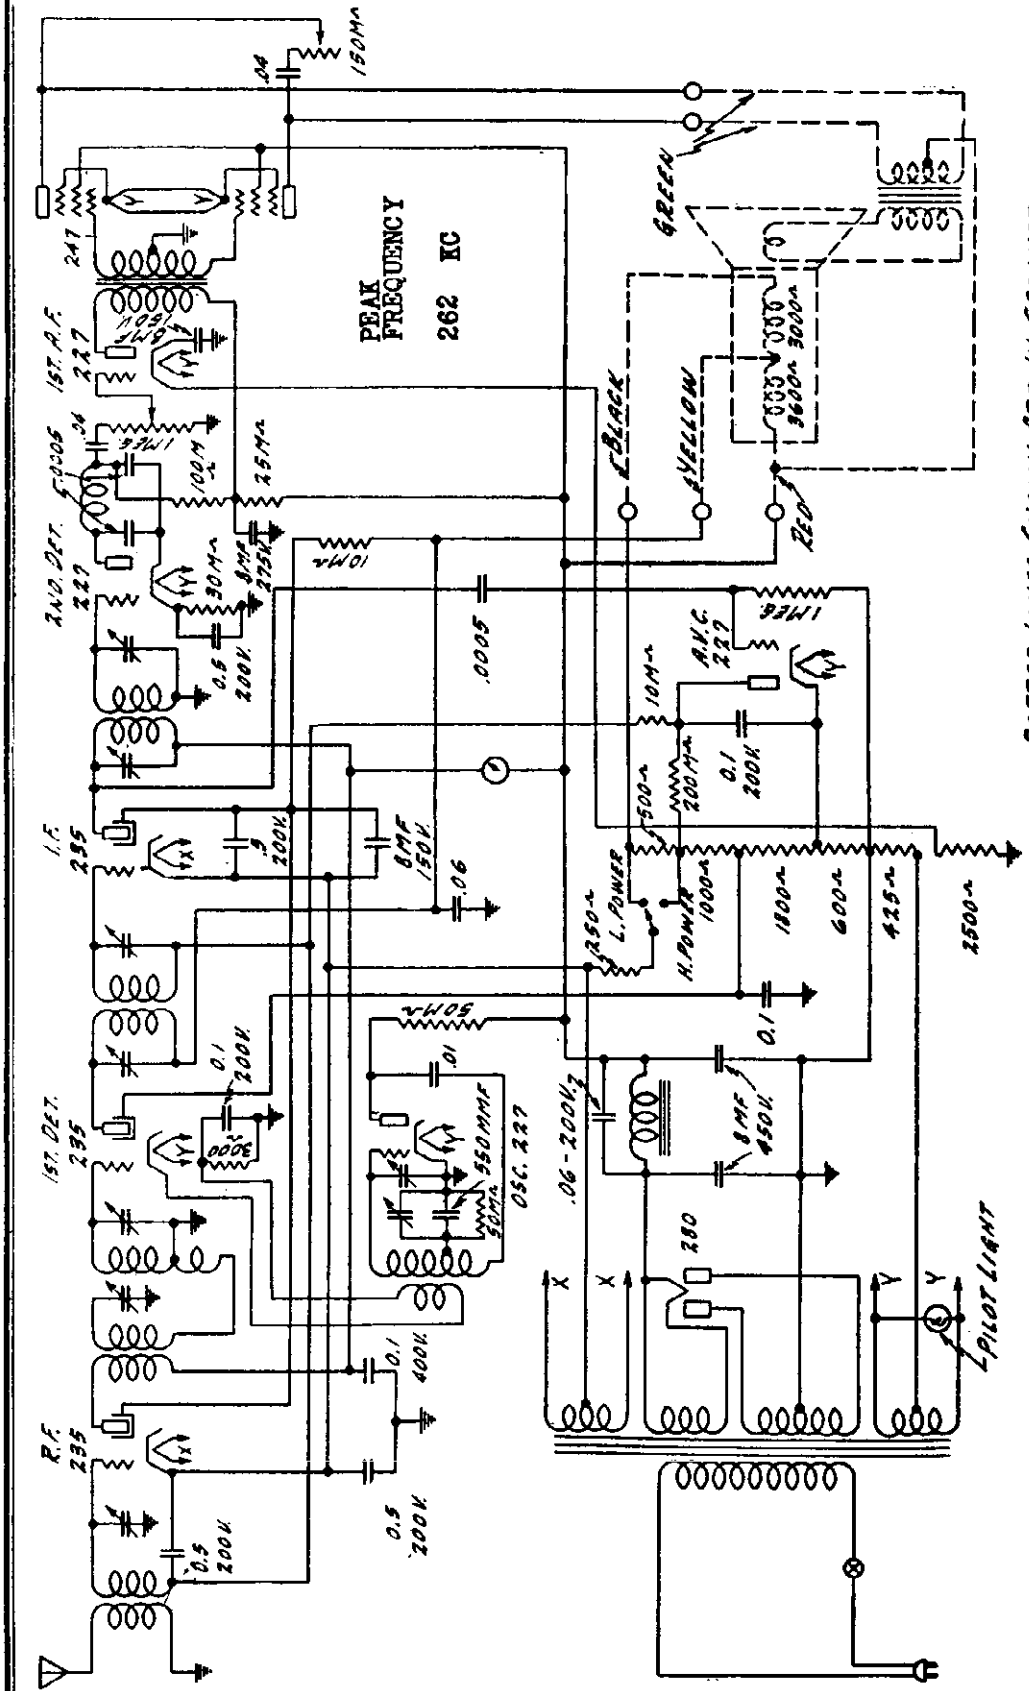

CAUTION: Do not attempt to operate on current other than that noted on instrument.

INSTALLATION: "ANT" may be fed from "B'LT-IN-ANT" lead, indoor or outdoor aerial, radiator, bed springs, or any large metal object, if desired. **BALANCING:** The intermediate stage is carefully phased and sealed to 175 K. C. and should not be tampered with.

PHONOGRAPH: Use a single pole switch mounted as near as possible to the second detector socket, connect in series with lead from ground end of

SONORA

MODEL 71, 72, 73 Schematic

The 25 cycle chassis can be operated satisfactorily from a 60 cycle power supply. If there is excessive hum it will be necessary to secure a .06 Mfd. condenser, Part No. 2854, and connect it in the circuit across the filter choke. The reverse is not true, that is, the No. 10, 60 cycle receiver cannot be operated satisfactorily from a 25 cycle power supply.

Aligning R.F. and Oscillator Condensers—For adjusting the R.F. and oscillator condensers the signal input from the antenna post should be made to the antenna post.

									Per Plate	

- (1) This voltage read across 800 ohm resistor.
- (2) Voltage as read with 600,000 ohm meter.
- (3) Varies with setting of localizer. Voltages read with high resistance meter
- (4) Current zero with no signal and localizer at normal position.
- (5) The voltage read across 200 ohm section of voltage divider.

SETTING THE LOCALIZER.

Turn the localizer knob counterclockwise as far as it will go. Then turn the knob one quarter turn clockwise. Next tune in a fairly strong signal and reduce the volume by means of the volume control knob on the front panel. Then turn the localizer knob to the extreme clockwise position. This will cause plate current cutoff in the RF and IF tubes. Then turn the knob slowly in a counterclockwise direction until the signal is again heard. With a slight additional turn in the same direction the signal builds up sharply to full strength and this is the correct position of the localizer setting. This adjustment should not be changed unless the set is reinstalled or the tubes are changed. Incorrect adjustment of this knob will control the action of the AVC tube in such fashion that the automatic action will commence too soon or too late.

Service Data

SPARKS WITHINGTON CO.

Service Data for Sparton Ensemble Model 30
Automatic Phonograph Mechanism

The automatic phonograph mechanism of the Model 30 SPARTON Ensemble consists of three principal divisions: The Power Source, the Tripping mechanism, and the Discard-Indicating mechanism. A description of the construction and function of each division is outlined in the following paragraphs.

POWER SOURCE

The Power Source consists of (Fig. 1) Motor 1381 mounted between Top Plate C-893 and Bottom Plate C-619, which are held parallel by (Fig. 2) Spreader 1251 and together by (Fig. 1) eight screws 1383. A worm in the Motor Shaft meshes with the Worm Gear, on the Turntable Shaft and causes the Turntable Shaft to revolve. A portion of this shaft protrudes below the Worm Gear Chamber. On this portion of the shaft (Fig. 2) Pinion 1207 turns freely. It is held in position by Thrust Washers bearing on the end of (Fig. 1) Sleeve 1266, on which Clutch Spool 1206 is mounted and held by Pin 1351. This pin holds the Sleeve integral with the shaft, but allows the Clutch Spool to travel up and down. The pin works in the Slot on the Clutch Spool. The Clutch Spool always revolves with the Turntable Shaft. Raising the Clutch Spool causes one of its three teeth to mesh with one of the two teeth in (Fig. 2) Pinion 1207, causing Pinion to turn with the Turntable Shaft. The teeth of this pinion mesh with the teeth in the (Fig. 1) Compound Intermediate Gear A-6138 causing it to revolve, then the teeth in the Compound Intermediate Gear mesh with the teeth of (Fig. 2) Cam B-3715 and causes the cam to revolve in a clockwise direction. The Compound Intermediate Gear and Cam are held in position by Pivot Studs in The Top Plate, and (Fig. 2) Pivot Bearings, 1262 which are adjustable, and locked into The Bottom Plate by means of Nut 733. These Pivot Bearings should be adjusted so the shafts turn freely, but do not move up and down. Cam B-3715 is the "heart" of the mechanism. All motions and power are derived from it, except the Power for (Fig. 3) Turntable C-617-A which is revolved by (Fig. 1) Rubber Washer 1392-1 acting against Metal Washer 1321-2 which is driven by a pin through

the top of the Turntable Shaft. The thrust from the Turntable Shaft is taken by (Fig. 1) Thrust Screw 1255-A, which is locked in position by Nut 773.

TRIPPING MECHANISM

When a record has been reproduced the needle in (Fig. 1) Pickup Unit A-6138 travels into the center of the record by means of the eccentric groove on the spiral groove depending upon the type of record. This motion is transmitted through Pickup Arm C-631 which is pivoted to (Fig. 3) Bracket 1269 by (Fig. 2) pivot screws 1270. (Fig. 3) Bracket 1269 is pivoted between the Top and Bottom Plates, at the top by (Fig. 2) Pivot Stud 1263 which is held in position by Top Support 1242-A, and at the bottom by Pivot Bearing 1262. The motion of (Fig. 1) Pickup Unit A-6138 causes (Fig. 3) Bracket 1269 to move on a vertical axis. In case of Spiral Groove records (Fig. 2) Pawl Arm 1234 attached to Bracket 1269 moves in and out, causing Spiral Pawl 1245 to raise Trip Lever 1238. In case of Eccentric Groove records Eccentric Pawl 1246 raises Trip Lever 1232. This causes Throw-Out Lever 1276 to be released, allowing it to travel downward and act on (Fig. 1) Clutch Lever 1277-A which pivots on Stud 1467. This allows the forked end to travel upward, which causes Clutch Spool 1206 to also travel upward, and its lugs engage with the lugs on (Fig. 2) Driving Pinion 1207, causing Pinion 1207 to turn which turns Cam B-3715 through (Fig. 1) Compound Intermediate Gear A-6138. When the cam (Fig. 2) B-3715 has nearly completed its cycle the Lug on it passes under the cam surface of Throw-out Lever 1275, causing it to rise and be held in position by allowing the notch in Trip Lever 1265 to engage under the projection atop in Throw-out Lever 1276. The Lug also prevents (Fig. 1) Clutch Lever 1277-A from rising. This holds Clutch Spool 1206 in mesh with (Fig. 2) Drive Pinion 1207 placing a strain on Spring 1366. When the Lug passes over the end of (Fig. 1) Clutch Lever 1277-A, the end snaps up, the forked end snaps down, and causes Clutch Spool 1206 to disengage from (Fig. 2) Pinion 1207. This stops the cycle operation.

MOVEMENT OF PICKUP

The (Fig. 1) Pick-up Unit A-6126 is moved by means of (Fig. 3) Follow Arm 1271 attached to (Fig. 1) Pick-up Unit Arm C-621 by (Fig. 3) Screws 13830-7 and 13830-9. The Follow Arm is moved by a Pin on the end of it which travels in a groove on the top of (Fig. 2) Cam B-3715. One quarter of the way around the top of the Cam there are two grooves. When the Pin is in the inner groove, the needle in (Fig. 1) Pick-up Unit A-6126 will lower at the starting position for 10" records. When the Pin is in the outer groove the Pick-up Unit will lower at the starting position for 12" records. Cam Track Switch 1268 (not shown) changes this pin into groove required. This is done by (Fig. 3) Switch Cam 1297 being raised up by Shift Lever 1303-A, which is pulled forward by Piston A-6133 in Solenoid A-6135-A which is energized by the Indicator Switch described in a subsequent discussion. When Switch Cam 1297 is pivoted on Bracket 1307-A, is in contact with Finger 1305-A it causes the inner side of (Fig. 2) Cam B-3715 to rise, making it engage on lower lug of Cam Track Switch 1268 (not shown). This changes the position of the Cam Track Switch, causing the necessary movement for the Pick-up Unit to lower to the starting position for 12" records.

DISCARD-INDICATING MECHANISM

(Fig. 3) Lift Lever 1302-A attached to Shift Lever 1303-A, is caused to rise at each revolution of the (Fig. 3) Cam B-3715 by a roller acting on a perpendicular surface inside of the cam. If (Fig. 3) Shift Lever 1303-A is in the proper position to raise Cam 1297 it also will cause end of Lift Lever 1302-A to rise under the low part of (Fig. 2) Roller Arm 1471, causing Roller 1243 to rise on largest perpendicular cam surface on Cam B-3715. This causes (Fig. 1) Discard B-3711-AA to be pulled back into the proper position to discard 12" records. If (Fig. 3) Shift Lever 1303-A is not in the forward position, Lift Lever 1302-A does not come up under the low part of (Fig. 2) Roller Arm 1471 and the Roller travels around on the smaller perpendicular surface of Cam B-3715 and the (Fig. 1) Discard B-3711-AA stays at the proper position to discard 10" records. These two discard motions are accomplished by the fork in (Fig. 3) Roller

Arm 1471 engaging in the fork of (Fig. 1) Yoke 1238 which is attached to the top and bottom plate by (Fig. 3) Links 1217 and (Fig. 1) 1440 so the entire Discard Mechanism B-3711-AA can travel back and forth being controlled by (Fig. 3) Roller Arm 1471, which acts on either of the perpendicular cam surfaces on Cam B-3715. To (Fig. 1) Link Yoke 1238 Links 1235 are attached. These Links are also attached to Discard Arm B-3711 and Shoe 1226. This gives a parallel motion to the Discard Arm up and down. This movement is accomplished by (Fig. 3) Lift Lever 1224 acting on (Fig. 1) Shoe 1226, when (Fig. 2) Lever 1223 is raised and lowered. Lever 1224 is raised and lowered by Lever 1279-A which is acted upon by the stud in it being in contact with the bottom surface of Cam B-3715. The inward motion of the Discard Arm is caused by the tension of Spring 1370 and is stopped by Stop Stud 1378. This relieves the pressure of Roller 1243 and allows Roller Arm 1471 to drop from the 12" record position to the 10" record position when the Roller is at the neutral part of cam surface. To prevent this roller from dropping down at any other time, (Fig. 1) Roller Arm Holdup 1453 is made use of, because (Fig. 2) Roller Arm 1471 is always over the vertical leg of (Fig. 1) Hold-up Arm 1453 when it is acting on the 12" cam surface. Repeat Lever 1377 is used when the continuous playing of one record is desired. This Lever when moved in, comes under Link 1226, making it impossible for Discard Arm B-3711 to Lower to the position to discard a record. (Fig. 3) Rest Hook 1249 is made use of when loading records. When Follow-Arm 1271 is placed on this hook, (Fig. 3) Discard Hold-up B-3712 is brought over (Fig. 2) Lever 1279-A, preventing it from acting to lower (Fig. 1) Discard Mechanism and remains in this position until it is pushed out by the Lug on (Fig. 2) Cam B-3715. This is why the Pick-up Unit can be brought to the center of the record and tripped without discarding the record, thus enabling the needle to start in the proper position, according to the record that is to be reproduced.

When (Fig. 1) pick-up Unit A-6126 causes mechanism to trip and begin a cycle of operation due to motion transmitted through it via the spiral or eccentric groove of the record, it is immediately swung away from the center of the record and pivoted above the edge of the turntable. At the same instant the pick-up Unit has

SPARKS WITHINGTON CO.

MODEL 30
Service Data

SERVICE DATA FOR SPARTON ENSEMBLE MODEL 30 PHONOGRAPH MECHANISM

lower parallel arm of the indicator switch rides when the shaft turns as described.
When the roller of the indicator switch rides on a 10° record, the other roller attached to another parallel arm, to which is also fastened another switch contact, does not rest on any surface and this switch remains unclipped.

When the switch sets on a 12° record both rollers rest on the record thus closing the switch. When this occurs, the closing of the switch energizes solenoid A-6135-A, which causes plunger A-6136 to be moved, which in turn actuates switch Cam 1297 attached to it.

The movement of switch Cam 1297 causes switch 1288 (not shown) to move the pin on the end of Follow Arm 1271 from the inner to the outer groove on (Fig. 3) Cam B-3715.

When this is done (Fig. 1) Pick-up Unit A-6126 lowers at the position to start a 13° record.

stopped in its travel away from the center of the record the Finger on (Fig. 2) Cam 1290 attached to the top of Cam B-3715 engages with indicator finger A-7689 attached to indicator unit shaft A-6099.

Cam B-3715 revolves further, exerts additional influence on the indicator finger causing (Fig. 3) indicator C-621 and kick-off arm A-6117 attached to it to describe a half circle. Kick-off Arm A-6117-A pushes record to be discarded into the receiving compartment.

When the Kick-off Arm A-6117-A has swung through its arc of travel outward, indicator Switch B-3710-AA rests on the top record of the group on the turn table. This switch reaches this position only when the arm has completed its arc of travel, and is not visible when the arm has reversed its direction of movement.

This is due to a sloping edge cut on the (Fig. 1) indicator shaft bushing A-6121 onto which the

IF SMOOTH PART OF RECORD FROM THE SMOOTH PART OF RECORD into the grooves it is probably due to the (Fig. 1) Pick-up Arm C-621 being tight or not properly adjusted. (Fig. 3) Bracket 1269 should be tilted toward the discard compartment at top, which gives a natural tendency for the (Fig. 1) pick-up Unit A-6126 to swing toward the center of record. This can be effected by loosening screws which hold (Fig. 2) Top Bearing Plate 1242-A and moving the Plate to the proper position. If Pick-up Arm is then out of center with the hole, it can be readjusted by Pivot Screws 1270.

ADJUST POSITION OF (FIG. 1) KICK-OFF ARM A-6117-A.
When the Kick-off Arm is in a stationary position the finger on the end should clear a 12° record by about 1/8", when the record is being raised from the turntable as shown in Fig. 1. The position of the Kick-off Arm is regulated by (Fig. 3) finger A-7689 bearing against Cam A-6128. This finger is adjusted by the adjusting screws in adjusting block A-7697. The adjusting block is fastened to spindle A-8022 by set screw 1371.

HEIGHT OF (FIG. 1) GUIDE RAIL B-3709-A. The height is regulated by the position of nuts A-47-N.
BE SURE THAT ALL JOINTS OPERATE FREELY AND SMOOTHLY. A little oil in all joints and wearing surfaces will insure this condition.
BE SURE THAT ENSEMBLE IS STANDING REASONABLY LEVEL.

Adjustments on the Model 30 Automatic Phonograph Mechanism

To this adjustment. It is possible to change this adjustment by bending the lever, in cases where (Fig. 3) Stud 1467 is not in a slot.
TO ADJUST (FIG. 1) DISCARD ARM B-3711 FOR HEIGHT use set screw in (Fig. 2) Lever 1279-A. The discard arm should be adjusted so that 12° records just clear the top of (Fig. 1) Spindle A-6137-A when the Arm is in its highest upward position.

TO ADJUST (FIG. 3) DISCARD TONGUE A-6099-A, adjust screw A-1255-8. The proper distance for this adjustment is when Roller A-6089 rests on record, (Fig. 1) Discard Arm B-3711 is in the down position, and there is just room for the tongue to pass under a normal size record.
TO ADJUST (FIG. 1) DISCARD ARM B-3711 IN AND OUT adjust (Fig. 3) Discard Tongue A-6099-A so that it will just come down behind a record in its lowest position, using screws which hold Roller Bracket (Fig. 2) 1472-A to Roller Arm 1471.

IF MECHANISM TRIPS HARD, it is probably due to the fact that the notch in (Fig. 2) Trip Lever 1233 is not smooth or not machined at the correct angle. Also, it may be due to the fact that Spring 1265 has too much tension. Throw-out Lever 1275 should rise high enough when the Lug in Cam B-3715 is passing under it to allow the notch in Trip Lever 1233 to enter under the Lug on Lever 1275.

CAUTION—Be sure that you understand exactly what the trouble is with the mechanism before starting to repair it. Do not attempt to "doctor" or "experiment". Remember, the mechanism operated perfectly at the factory.
TO ADJUST UNIT A-6126 COMES SO (FIG. 1) THE PROPER PLACE, adjust (Fig. 3) Screws 12630-7 and 12630-8 in and out as required. Keep the front surface of Follow-Arm 1271 parallel.

TO MAKE (FIG. 3) STOP SWITCH 1412-AA CUT OFF AT THE PROPER PLACE which occurs when (Fig. 1) Pick-up Unit A-6126 drops to its lowest position with no record on the Turntable, adjust screws which hold (Fig. 3) Stop Switch 1412-AA by loosening or tightening the front screw and the holdout screw where the Stop Switch fastens to the top plate.
TO ADJUST MECHANISM SO NEEDLE TRIPS ON INNER CIRCLE OF COLUMBIA RECORDS adjust (Fig. 2) Pawl Arm 1234 by means of screws which attach it to Bracket 1269 so that Pawl Spiral 1245 trips on vertical part of Trip Lever 1233. Spiral Pawl 1245 should clear serrated surface on Trip Lever 1234 by about 1/32".

TO ADJUST (FIG. 1) CLUTCH LEVER 1277-A, loosen Stud 1467 which is in a slot on Bracket 1244, until upper end of Clutch Lever clears the Lug on Cam B-3715 by about 1/32" when Clutch Spool is up as far as it will go. If Clutch rattles or fails to operate properly, it is

Service Data for Sparton Ensemble Model 35 Automatic Phonograph Mechanism
GENERAL OPERATION

At the completion of the reproduction portion of a record, the needle moves into the groove in the center of the record. The first oscillatory movement of the needle on an eccentric groove record, or the feed-in movement on a spiral groove record trips Trip Lever 814, figure 1.

Dog 813 figure 2 for eccentric groove records and Spiral Trip Dog 533 for spiral groove records is attached to Pick-up Arm Lever 811 by means of Adjusting Stud 860 and Adjustment for Pick-up Lever 812. Pick-up Arm Lever 811 is attached to Pick-up Unit 904, figure 3 by means of Yoke 867 and Pick-up Arm 866 which is connected to Bracket 810 figure 4, onto which Pick-up Arm Lever 811, figure 3 is attached by means of two screws 155 figure 4. This whole device is allowed to swing from right to left due to its attachment to Standard 788 by the Dog Point Set Screws 823 which fit into the Bearing in Bracket 810.

When Trip Lever 814 figure 1 is tripped, it allows Throwout Lever 822 to drop, and this causes Clutch Lever 816-C to push Clutch 826 into the Pins of Clutch, Collar 527-C which is revolving; acting through Worm Gear 514-C which is driven by the Worm in Drive Shaft 793 connected to Motor by means of Drive Spring 877. The connecting of this Clutch causes worm shaft 524-C which is meshed with Cam Worm Gear 528-C to cause Cam 789 to revolve and lower the Turntable to the "swing back" elevation. This is accomplished by Lift Lever 817 figure 2 which is operated by Cam 789 figure 1 acting on the bottom of Turntable Shaft 607-C, through Turntable Lift 516 figure 2 and Adjustment 618 to which the Turntable Shaft is attached.

Turntable 510-C figure 1 is driven in a clockwise motion by means of Worm Gear 583-C (not shown), which is meshed with Drive Shaft 793. This Worm Gear is provided with inside lugs which fit into the grooves in Turntable Shaft

507-C* and allows the Shaft to raise up and down without interfering with its turning motion.

DISCARD POSITION OF TURNABLE

Returning to the action of Cam 789 figure 1 as it rotates further, Turntable 510-C* drops to the discard position, allowing the record to come in contact with Discard Rubber 660 figure 4. This raises the record above Receiving Stud 508 figure 3 and the rotation of Turntable 510-C* then causes the record to be discarded into the Receiving Compartment.

"SWING BACK" OF PICKUP UNIT

Before the Cam 789 figure 1 allows the Turntable to be moved into the discard elevation, and while the Turntable is still in the "swing back" elevation, the Pick-up Unit is swung away from the record by means of Index Lever 815 figure 2 which is connected to the Pick-up Arm through Pick-up Arm Lever 811. The inner end of the slot in Index Lever 815 acts on Pin 763 figure 1 that revolves with the Cam in a clockwise motion. It is through this means that the Pick-up is swung away from the record.

SLIDE MOVEMENT FOR 10" RECORDS

When Cam 789 figure 1 starts to revolve, Eject Arm 790 figure 2 also starts to revolve as it is driven by Dog 822. Roller 662 attached to Eject Arm 790, travels in the slot in Drive Lever 550 and causes it to move from the left to right, which moves Eject Slide 835-C and brings the center of the record over Receiving Pin 508 figure 3 in Turntable 510-C*. This motion is caused by Drive Lever 560 figure 2 acting through Link 852 attached to Lever 865 which is pinned to Shaft 558 connected to Top Lever 863-C which acts on Transverse Lever 854-C through Link 866. The Transverse Lever is connected to the twelve inch record Regulating Lever 869 which is fastened to Eject Slide 835-C by means of the Stud in the "I" shaped slot. This Stud remains in the "I" end of Lever

869 and allows Slide 835-C to place a ten inch record in the proper position over Receiving Stud 508 figure 3.

SLIDE MOVEMENT FOR 12" RECORDS

In case a twelve inch record is on the Slide, Centering Lever 860-C figure 4 is pushed out by the record to a position where its tail end trips the twelve inch Regulating Lever 859 figure 2. Eject Slide 835-C moves forward, causing the Stud to leave the "I" end of the slot in Lever 859 allowing Eject Slide 835-C to travel just far enough to place a twelve inch record over Receiving Stud 508 figure 3.

Ten or twelve inch records can be used without discrimination. The engagement of the needle on ten or twelve inch records is controlled by Engaging Regulator Weight 872 figure 4 acting on Cable 900 which is attached to Index Lever 815 figure 2. When the Weight is allowed to act, Index Lever 815 is pulled over and the long slot engages on Pin 763 figure 1 causing the Pick-up Unit to swing into the proper place to engage on a 12" record. If Regulator Weight 872 figure 4 is not allowed to act, Index Lever 815 figure 2 is carried over by means of Drag Link 530 figure 1 so that the short notch engages on Pin 783 and the needle engages at the proper place to start a 10" record. Whether or not the Weight 872 figure 4 is allowed to act depends on Shaft 824 which, when under Weight 872, keeps the Weight from acting. Shaft 824 is controlled by Engaging Regulator Arm 787.

When a 12" record is fed out, Centering Lever 850-C figure 4 is pushed out. The Finger end of carries Arm 787 out with it, swinging end of Shaft 824 from under Weight 872, allowing 872 to act. Shaft 824 will remain in this position until a 10" record is fed out of the Hopper. Thus, a 12" record may be repeated on the Turntable as many times as desired. When a 10" record is fed out of the Hopper, Eject Slide 835-C figure 2 goes out further over the Turntable, allowing Pin 887 to come in contact with Arm 787 causing it to move so that Shaft 824

takes a position under Weight 872 and prevents it from acting. This position will be held until a 12" record is fed out of the Hopper, thus, a 10" Record will continue to repeat until the position of Shaft 824 is changed.

RECEIVING POSITION OF TURNABLE

Again returning to the motion of Cam 789 figure 1 further rotation of this Cam causes the Turntable to rise to receiving elevation, in time to receive the record which has been moved to the positions just described. The Turntable remains in this position while the Cam rotates further, allowing Roller 662 figure 2 which is attached to Eject Arm 790, to travel in the slot in Drive Lever 560 and return Eject Slide 835-C to its original position. As soon as Eject Slide 835-C has returned to this position, Cam 789 figure 1 has revolved to a position where it allows the Turntable to drop to the "swing in" elevation.

"SWING IN" MOVEMENT OF PICK-UP UNIT

At this time Pin 763 figure 1 has revolved far enough to connect with either the ten or twelve inch notch in Index Lever 815 figure 2. Its further revolution causes the Pick-up to swing in over the record so the Needle rests on the smooth part of the record as the Turntable is raised to reproducing elevation by means of Cam 789 figure 1. Regulating Weight Lever 872 figure 4 on Standard 788 now causes the Pick-up to move over from the smooth part of the record to the first reproducing groove. Reproduction of the record begins at once.

COCKING MECHANISM AND STOPPING CYCLE OF CAM

When the Pick-up Unit first swings away from the record, Pick-up Arm Lever 811 figure 2 passes under the tail of Throwout Lever 822 figure 1, causing it to rise to a position where the notch in Trip Lever 814 is allowed to enter its proper place under the lug in Throw-out Lever 822, holding Throwout Lever 822 in this

SPARKS WITHINGTON CO.

MODEL 35
Service Data

(Continued)

position after the Pick-up Arm Lever 811 *figure 2* no longer supports it. When the Throwout Lever is raised to this position, a spring tension is created which pulls on Clutch Lever 816-C *figure 1* attempting to pull back and open Clutch 826 but Clutch Lever 816-C is held in the engaging position by means of Control Disc 864-C until the Cam has completed its entire revolution when a notch in the Control Disc allows the Clutch Lever to follow the urge of the spring and disengage the Clutch.

REPEATING

In case it is desired to play the same record over, the repeat Button *figure 5* is moved to the left. This moves Repeat Lever 806 *figure 2* causing it to press against Drive Dog 822 causing the Dog to recede and not catch on Eject Drive Arm 790. Eject Drive Arm 790 remains stationary and the Eject Slide does not move. The Cam revolves and the Turntable goes through all of the elevating positions except the discard elevation. Eject Arm 790 does not allow Roller 845 to drop to the discard elevation in Cam 789 *figure 1*, thus the record will be repeated until the Repeat Lever is moved to the right.

CONTROL OF RECORDS

When Eject Slide 835-C *figure 4* comes forward, the bottom record is caught between the "Y" shaped plates 836 and 837 *figure 3* which brings the bottom record forward with the Slide. The other records slide over the top of these "Y" shaped plates and remain in the Hopper. Only the bottom record is allowed to come out of the Hopper onto the Turntable. Other records are prevented from coming out by means of the two Admitters 819-C which are devised so they gauge themselves according to the thickness of the record. Thick, thin or warped records are fed out through the action of the admitters without injury to the records or mechanism. The admitters are held down against the record by means of springs and are adjusted by Screws 902. Back Stops 871 prevent records from sliding too far back in Hopper.

If a ten inch record is on the bottom and is not in the center, it is forced into the center by the two Centering Levers 850-C *figure 4* and 848-C *figure 3* which are held in position under tension by Springs 569 *figure 1* and 565 *figure 2*. These Springs are right and left hand and are attached to bushings in Studs, which have right and left hand threads and have a tendency to keep the spring from unscrewing the studs and nuts which hold them.

These Springs hold the Centering Lever against the Stop Pins which are set so that they hold the Centering Levers just the right distance to allow a 10" record to pass through with a slight amount of tension. In case a 12" record is on the bottom, these Springs are allowed to open up and the Centering Lever 850-C *figure 4* acts to trip the mechanism as described under the paragraph about Slide Movement for 12" records.

THE STARTING BUTTON

In starting or rejecting records, the Starting Button *figure 5* is pressed. When this Button is pressed slightly, it causes the contacts in switch 897-A *figure 2* to be spread apart which changes the fields in the motor from a series connection to a parallel connection for a greater starting torque. Pressing down further causes Lever 662 *figure 2* to act against Throwout Lever Trip 814 and trip mechanism which discards the record. This is the same action as though it were tripped with the Dogs 813 or 814.

THE CLUTCH SWITCH

Clutch Switch 895-A on Bracket 876 *figure 1* is operated by Clutch Lever 816-C by means of a fibre switch Opener, the purpose of this switch is to allow switch 895-A *figure 4* to be opened when the Clutch is engaged and the Cam is in motion. This carries the current whenever Clutch is in motion and the Pick-up Unit is not resting on a Record.

FIGURE 5

THE PICK-UP UNIT SWITCH

Pick-up Switch 898-A *figure 4* is attached to the back of Standard 788. When the Pick-up is not resting on a record, the Pick-up Arm drops down, swiveling at Trunion Pin 641, *figure 3*. This allows the Brake Shoe on Pick-up Arm 866 to rise and press against Cork Insert 623 *figure 4* which is in the Brake Adjustment 686. This retards the Swinging action of the Pick-up and allows it to move only when forced by Index Lever 816 *figure 2*. This Brake Adjustment 686 can be regulated to bring the Pick-up to the height desired and is locked in place by a nut.

Through the center of Brake Adjustment 686 is a Fibre Rod 590 *figure 4* which also rests on Brake Shoe 974 and is raised whenever the Brake is closed. The upper end of this acts on the Contact Spring in Switch 898-A and causes it to open the Switch and break the entire circuit, acting the same as the Clutch Switch in parallel with it. With both of these switches open, the power supply is entirely cut off. Also, when this switch is open a contact is formed with the upper part of the Switch which cuts out Speed Regulating Rheostat No. 544 *figure 2* and allows the full power to be used while the Cam is in the operating cycle.

Lubrication on the Sparton Ensemble Model 35 Automatic Phonograph Mechanism

The Model 35 automatic phonograph mechanism is thoroughly lubricated at the factory when assembled and requires no oiling or greasing except as noted in this section.

THE ELECTRIC MOTOR ARMATURE SHAFT BEARINGS. Oil once every six months. Use nothing but light fine oil. Located on the

upper side of the motor board *figure 5* are two (2) pipe plugs marked "OIL." Remove these plugs and inject a quantity of oil in the tubes under them. This lubricates both armature shaft bearings. The wick type oil wells used on the bearings keep the bearings well lubricated for a six (6) months period of normal operation.

MODEL 35
Adjustments

SPARKS WITHINGTON CO.

consistency of vaseline, mixed with graphite if possible. In the main body casting, housing the turntable shaft and worm gears two (2) pipe (2) pipe plugs 687 *figure 4* marked "Grease." Remove these Plugs and inject a small quantity of grease in the openings.

KNUCKLES, JOINTS AND BEARINGS. Oil once every six (6) months. Use nothing but light fine oil.
AUTOMATIC MECHANISM GEARS AND BEARINGS. Grease once every year. Use nothing but a good grade of grease of about the

Adjustments on the Sparton Ensemble Model 35 Automatic Phonograph Mechanism

ADMITTERS 819-C. *FIGURE 3.* Use Adjusting Screw 902. Turning this screw in a clockwise direction raises the end of the admitter higher. The height of the admitter should be just enough to touch a record on the Eject Slide 835-C *figure 2* when the slide is out.

ALIGNMENT OF MOTOR DRIVE SPRING 877. *FIGURE 1 WITH DRIVE SHAFT 793.* Two adjustments are provided for this purpose. One for aligning the spring if it is horizontally off center with the drive shaft and the other for alignment if the spring is vertically off center.

To align the spring if horizontally off center loosen the four collars (see 574-C, *figure 1*) on Screw Studs 797. This will then allow either side of Motor 895-C to be moved back or forth on the studs as the case demands. To align the spring if off center vertically, the Hex. nut on Stud 799 should be loosened or tightened depending upon whether the motor is to be tipped up or down.

PICKUP UNIT TO STRIKE AT PROPER PLACE ON RECORD. Use adjusting Screw 535 *figure 2.* The needle in the Pickup Unit should strike about 1/8 inch in from the outside edge of the record.

PICKUP UNIT TO TRIP MECHANISM ON SPIRAL GROOVE RECORD. Use adjusting Screw 812, *figure 2.* The mechanism should trip

Eject Slide should carry out a 10 inch Victor record to a distance where the tip of Receiving Stud 508, *figure 3,* enters the hole in the record at the front side of the hole. If a 10" Columbia record is used to make this adjustment, the stud should enter the hole in the record at the rear side.

END PLAY IN CAM WORM SHAFT 524-C. *FIGURE 1.* Use Adjusting Screw 525-C. The end play in this shaft should be just enough to be detected when shaft is moved back and forth by hand. If end play is too great, the clutch will remain engaged and the mechanism will not automatically stop when the last record has been reproduced.

PICKUP SWITCH 898-A. *FIGURE 4.* This switch is adjusted by loosening the two screws turntable shaft and worm gears are located two by which it is fastened to standard 788, and moving it up or down so the contacts will close when the pickup unit is on a record in reproducing position.

CLUTCH SWITCH 896-A. *FIGURE 1.* This switch is adjusted by loosening the two screws

which hold Bracket 876 to the body casting and moving the bracket one way or the other so the contacts will close when clutch 526 is in gear. Clutch 526 is placed in gear immediately after a record has been discarded automatically or manually.

END PLAY IN DRIVE SHAFT 793. *FIGURE 1.* Use Adjusting Screw 706-C, *figure 4.* The end play in this shaft should be just enough to be detected when shaft is moved back and forth by hand. If end play is too great, the reproduction of a record will have a wavering effect.

SPRING TENSION ON CENTERING LEVER 842-C and 850-C. *FIGURE 4 and 3.* **RESPECTIVELY.** Use Adjusting Screws 847 and 849, *figure 4.* The spring tension on these levers must be equal and sufficient to hold the center of a record in a line with Receiving Stud 508, *figure 3.* If the tension is insufficient or unequal, Eject Slide 835-C, *figure 2,* will not center the record over turntable 510-C. Loosen these screws and turn them to the right or left to increase or decrease tension as the case demands.

Resistor Data

SPARKS WITHINGTON CO.

STANDARD RESISTOR COLOR CODE AND RESISTORS USED IN SPARTON RADIO RECEIVING SETS AND SPARTON ENSEMBLES

Standard Resistor Color Code

- 0—Black
- 1—Brown
- 2—Red
- 3—Orange
- 4—Yellow
- 5—Green
- 6—Blue
- 7—Violet
- 8—Gray
- 9—White

To determine the value of a resistor, the first significant figure of resistance value is represented by the color of the body of the resistor, and the second

figure of resistance value by the color of the tip of the resistor. The number of ciphers following the second figure is determined by the color of the dot or stripe in the center of the body of the resistor. For example, a 20,000 ohm resistor has a red body, black tip, with orange dot or orange stripe. A 2,200 ohm resistor would be red body, with red tip and red dot, or red stripe, and as all colors are the same, it would be a single color resistor.

How to Replace Cone Head in Magnetic Speaker in Model 51 and 52

First:

Remove the motor or speaker driving element by removing the four mounting screws, unsoldering the lead wires from the outside terminal lugs, and unsoldering the driving link from the diaphragm apex pin.

Second:

Remove the cone head and all paper rings from the speaker housing.

Third:

Coat the rim of the speaker housing where the paper ring on the diaphragm rests with an ample coating of cellulose cement (such as Du Pont's Household Cement or Ambroid).

Fourth:

Place the cone head (part No. B-3528) into position, set the speaker housing onto a flat surface with the opening of diaphragm down, place a weight on housing and leave until cement is dry.

Fifth:

Fasten the driving motor back into position with four mounting screws, making sure that the movable armature of the motor is in exact center between the pole pieces before mounting, and solder the lead wires to the terminal lugs.

Sixth:

Solder the diaphragm apex pin to the apex driving link, making sure not to exert any strain on the drive link which might put the motor armature out of center while soldering. The apex pin should be cut off before soldering, so that it will extend about ¼" along the drive link. Use ordinary soft solder.

Seventh:

Next cement the paper ring (part No. A-5847) and finally the paper ring (part No. A-5846) into position, using cellulose cement.

How to Adjust the Antenna Compensating and Equalizing Condensers

SPARTON MODELS 103, 235, 564, 570, 574, 578, 589, 591, 593, 600, 610, 620, 740, 750 AND 870. ALSO MODELS EQUIPPED WITH PHONOGRAPH PICKUP JACK MANUFACTURED PRIOR TO JUNE 1, 1936.

After the aerial and ground have been inspected and found to be in good order, and all tubes have been tested and placed in their proper sockets, the final operation in the installation of a SPARTON Radio Receiving Set in adjustment of the antenna compensating and equalizing condensers. This adjustment should ALWAYS be made with the use of a High Resistance Voltmeter as a resonance indicator. Using the ear as a resonance indicator should be resorted to only when it is impossible to employ a Voltmeter. Any 1,000 ohm per volt 0-60, 75 or 100 scale D. C. Voltmeter will serve the purpose. Connect two leads to the binding posts of the Voltmeter to be used, and terminate them in a phone plug which is then inserted in the Phonograph Pick-up Jack just far enough to touch the first inside contact. (See figure 2.) (DO NOT PLUG ALL THE WAY INTO THE JACK, as this will short out the Detector tube biasing resistor, and cause inaccurate readings.) Be sure that no Analyzer Adapters are connected to the end of the Analyzer Cord, or plugged into the Analyzer Socket, as this will short-circuit the Voltmeter.

NOTE: (When aligning Models 235 and 103, two small battery clips instead of a phone plug are fastened to the Voltmeter leads. On the Model 235 the leads are connected to terminals No. 11 and No. 13 of the terminal block located on the left-hand side of the cabinet. On the Model 103 the leads are connected to terminals No. 14 and No. 17 on the terminal strip.)

1. With aerial and ground wires connected to the set as they are to be permanently used, CALIBRATION OF DIAL STRIP ON SPARTON MODELS 103, 235, 410, 420, 564, 570, 574, 578, 589, 591, 593, 600, 610, 620, 740, 750 AND 870.
9. Note carefully whether or not a station around 600 kilocycles indicates correctly on the dial when tuned to the loudest volume.
10. If station reads off its proper setting, loosen the screws which hold the celluloid strip

PHONE PLUG INSERTED APPROXIMATELY 3/4 OF THE WAY INTO THE JACK OR JUST FAR ENOUGH TO OBTAIN A READING OF APPROXIMATELY 15 VOLTS WITH NO SIGNAL TUNED IN

11. Next, tune in a station between 1100 and 1300 kilocycles and see if it reads correctly on the dial.

12. If stations tune in to maximum volume at a setting different from station's correct kilocycle reading, turn dial to the reading the station should come in on according to its log-book reading. Then readjust the Condensers as explained in No. 1 to No. 5.

13. This final adjustment will scarcely affect the calibration of the stations around 600 kilocycles and will properly align the Selector Unit to its highest efficiency, and will cause the dial to read correctly over the entire broadcast spectrum. MODELS AR-19 AND 31

Due to the construction of these Models, it is not convenient to connect a Voltmeter at the proper place in the circuit so it can be used as a resonance indicator, therefore, a pair of ear phones are substituted for the speaker and are used as the means of determining when the antenna compensating and equalizing condensers have been properly adjusted.

1. With aerial and ground wires connected to the set as they are to be permanently used, tune in a DISTANT STATION between 80 and 90 or higher on the dial.
2. Turn Volume control down until station is barely audible.
3. Adjust Antenna Compensating Condenser with insulated handle screw driver to a point where the station sounds the loudest.
4. The Equalizing Condensers are numbered 1, 2, and 3, from front to back of receiver. Reduce the volume control until the station is barely audible and with the adjusting wrench, adjust

11. Next, tune in a station where the station sounds the loudest. Next adjust No. 1 and No. 2 in the same manner.

TO CHECK ADJUSTMENT

6. Tune in a station between 15 and 25 on the dial.

7. Readjust the Antenna Compensating and Equalizing Condensers No. 3, No. 1, and No. 2 in exactly the same manner as they were adjusted between the 80 to 90 setting of the dial. The purpose of this adjustment is to check the "tracking" of the four condensers. The volume of the station should decrease if any of the four original adjustments are properly adjusted. That is, the four tuned circuits must show alignment between 550 and 650 kilocycles on the ADJUSTMENT made at 1200 or higher kilocycle setting.

8. After the check at 550 kilocycles it will be necessary to again readjust the condensers as explained in No. 1 to No. 5 inclusive. This is necessary, due to the adjustments being slightly thrown off in the checking process.

in place and slide the strip so the reading is correct for the station being received.

NOTE: (On Models 410, 420—If station reads off its proper setting, loosen the screws which hold the dial drum to the condenser shaft and move the drum one way or the other, until the reading is correct for the station being received. When doing this be sure that the condenser shaft does not turn when the dial is moved.)

No. 3 to a point where the station sounds the loudest.

7. Next adjust No. 1 and No. 2 in the same manner.

TO CHECK ADJUSTMENT

6. Tune in a station between 15 and 25 on the dial.

7. Readjust the Antenna Compensating and Equalizing Condensers No. 3, No. 1, and No. 2 in exactly the same manner as they were adjusted between the 80 to 90 setting of the dial. The purpose of this adjustment is to check the "tracking" of the four condensers. The volume of the station should decrease if any of the four original adjustments are changed. That is, the four tuned circuits must show alignment between 15 and 25 on the dial on the adjustment made between 80 and 90.

TO READJUST

8. After the check between 15 and 25 on the dial, it will be necessary to again readjust the condensers as explained in No. 1 to No. 5 inclusive. This is necessary due to the adjustments being slightly thrown off during the checking process. SPARTON MODELS 410 AND 420

Follow the same procedure outlined for adjusting the antenna compensating and equalizing condensers for the SPARTON Models AR-19 and 31, except in this case ear phones are not substituted for the speaker as a means of determining when the condensers are properly adjusted. The speaker serves this purpose as it is, and as the dial is calibrated in kilocycles a station is tuned in between 80 and 90 as specified in paragraph No. 1, and the re-check is made between 500 and 600 kilocycles instead of between 15 and 25.

Resistor
Color Code

Standard Resistor Color Code and Resistors Used In Sparton Radio Receiving Sets and Sparton Ensembles

STANDARD RESISTOR COLOR CODE

0—Black	5—Green
1—Brown	6—Blue
2—Red	7—Violet
3—Orange	8—Gray
4—Yellow	9—White

To determine the value of a resistor, the first significant figure of resistance value is represented by the color of the body of the re-

sistor, and the second figure of resistance value by the color of the tip of the resistor. The number of ciphers following the second figure is determined by the color of the dot or stripe in the center of the body of the resistor. For example, a 20,000 ohm resistor has a red body, black tip, with orange dot or orange stripe. A 2,200 ohm resistor would be red body, with red tip and red dot, or red stripe, and as all colors are the same, it would be a single color resistor.

The resistance of the field as measured across the two large prongs of the speaker plug should be 1000 ohms.

The values of all resistors should check within not more than 20% when measured with an ohmmeter or bridge.

(Chassis 26)
Voltage, Data

STEINITE RADIO CO.

If a 175 kilocycle oscillator is available, the receiver may be aligned as follows: (all aligning operations should be made with bottom plate under act)

The output of the 175 K.C. oscillator is connected to the grid of the 1st detector tube and 125 m.a. thermo couple output meter is connected to the voice coil of the loud speaker. The two aligning condensers of each I.F. transformer should then be carefully adjusted for maximum output. These four condensers should be adjusted several times to be certain that all four circuits are tuned to exactly 175 K.C. (Use an insulated screw driver.)

After this has been done a station operating on about 1400 K.C. or preferably a modulated oscillator should be tuned in with the antenna or lead from the oscillator connected to the grid of the R.F. amplifier tube. The tuning dial should be set to correspond to the signal being used. That is, if a 1400 K.C. signal is being used, turn the tuning dial to read 1400 K.C. Then adjust the aligning condenser of the middle section of the gang condenser until maximum output is obtained. The next step is to remove the lead from the grid of the R.F. tube and connect it to the antenna binding post. DO NOT CHANGE THE TUNING DIAL WHILE DOING THIS. Then adjust the aligning condenser on the R.F. section of the condenser (the section at the rear of the chassis) until maximum output is obtained. After this has been completed the receiver is properly aligned at high frequencies.

Next set the oscillator at 600 K.C. or tune in a station near this frequency with the lead from oscillator or the antenna connected to the grid of the R.F. tube. Then adjust the oscillator aligning condenser (mounted in lower center front of chassis) for maximum output. This should be carefully done and at the same time the tuning dial should be changed slightly to see if maximum output is obtained. If it is found necessary to change the oscillator tuning condenser greatly it is well to repeat the aligning operation at the high frequency mentioned above.

	All filaments to ground-----	16.5 volts
	'51, '47, '27, and '24 filaments-----	2.4 volts
	'80 filament-----	4.7 volts

The following points should be checked if no signal are heard when a good set of tubes are used.

The oscillator may be checked for oscillation by reading the cathode voltage of the 1st detector. This is normally about 12 volts. Then touch the grid of the oscillator tube and if it is working properly the reading obtained on the cathode of the 1st detector will drop to about half the normal reading. If it is not oscillating various '27 tubes should be tried in the oscillator position and if still no oscillation is obtained connections in the oscillator circuit should be checked for continuity.

It will be seen from the wiring diagram that a special impedance coupling is used from the power detector to the power pentode. If the set "motor boats", check opens in this circuit or short circuit in the coupling condenser.

All filaments except that of the type 80 tube are taken from one winding of the power transformer. Bias voltage for '47's is obtained from the drop across a portion of the speaker field. This maintains the grid at a 16.5 potential relative to ground. The grid is connected through two 1/2 meg. resistors, by-passed at center by a .1 mfd. condenser. Should this condenser become open, a very pronounced hum will result. In case of excessive hum or poor quality, check these connections.

MODEL R-101, R-102
Service Notes

STEWART-WARNER CORP.

PENTODE SERVICE NOTES FOR MODELS R101-R102 series.

Pentode tubes in which the steady grid current is somewhat higher than average overload readily in the type of circuit used in the R101 and R102 series. Overloading of this type is evidenced in several ways;- by a distinct buzz in the speaker, by a peculiar fluttering reception that develops after the tube warms up and by short tube life. Troubles of this sort can be permanently eliminated by reducing the value of the resistance inserted in the pentode control grid circuit. Figure A shows the normal connection of the pentode control grid circuit in the above receivers. Shift the 500,000 ohm resistor from the normal position shown in figure A to that shown in figure B, namely between the blocking condenser and the junction of the grid leak and the control grid terminal of the pentode tube.

VOLUME DIFFICULTY IN R 102A.

If the output volume is below normal and the alignment is perfect, check the 2nd detector screen grid voltage and circuit. If it is appreciably below 20 volts when measured with a high resistance voltmeter, the 2 meg detector screen grid resistor is probably open circuited. Instead of replacing with a new unit, make the following changes, which as a matter of fact are now incorporated in the production models. The change consists of cutting out the 2 meg resistor and feeding the screen grid through the 500,000 ohm resistor that was previously used as the bleeder unit in this circuit. This change requires nothing more than the cutting of two wires and the soldering of two connections. This change will raise the screen grid voltage to about 30 volts. The diagrams below show the resistor terminal strip and the screen and plate circuits of the 2nd detector indicating the points at which the wires are cut and the new lead inserted. Cut wires at point marked "X" and make changes shown.

STEWART - WARNER CORP.

MODEL R-101, R-102
Service NotesADDITIONAL SERVICE NOTES FOR MODELS R101 and R102 Series

The following applies to oscillation troubles in the R102 series of receivers when the volume control is in an intermediate position. Tighten down all coil shields, then carefully realign the tuned circuits. This applies if the regeneration although excessive is not violently so. If the trouble is very pronounced, the aforementioned operations may not be of complete aid. In such cases the 2000 ohm suppressor resistor in the grid circuit of the oscillator tube should be cut out and shifted to the cathode circuit where it acts both as a suppressor and as a bias resistor. This resistor is the small red unit with the black end, that connects direct from the grid of the #27 oscillator tube to the oscillator coil. After disconnecting the resistor, resolder the open leads. Then remove the short bare wire from the cathode of the oscillator to the grounded lug on the padding trimmer condenser and connect the resistor between these two points.

Parasitic oscillation of the oscillator tube, evidenced by a continuous whistle, particularly upon the high frequency end of the dial is eliminated by the aforementioned change.

The phasing tool required to adjust the trimmers is part # T 70583 and is available at a cost of \$25. To align the tuned circuits it is necessary to remove the chassis. Remove the control knobs and the four hex head screws which hold the chassis in place. The speaker can be left in the cabinet since the leads are of sufficient length. The various trimmers are shown upon the chassis layout illustrated upon page 588-H. The IF transformers are of the tuned primary and tuned secondary type, each tuned by a separate trimmer. The IF trimmer adjusting screws can be reached thru small holes at the base of each shield, the primary in each case being at the left and the secondary at the right. If a commercial output meter is used it can be plugged into the television terminals, but a series condenser must be in one of the output meter leads. The test signal is fed into the 1st detector tube, the "A" lead of the oscillator being connected to the control grid, after the regular control lead has been removed. The IF peak frequency is 177.5 KC.

The RF and oscillator circuits require that the signal be fed to the receiver through the regular aerial and ground posts. Replace the control grid lead to the 1st detector. Ground the set and oscillator. Adjust the oscillator to 1400 KC. Tune the receiver to maximum output. Then reduce oscillator output until output meter reads half scale. Then tune "A" trimmer for maximum meter indication. If the output meter goes beyond full scale, REDUCE THE OSCILLATOR OUTPUT AND DO NOT CHANGE THE RECEIVER VOLUME CONTROL. Then adjust "B" and "O" trimmers for maximum output. The "O" trimmer adjustment is very critical. Then shift test oscillator frequency to 600 KC and tune receiver for maximum output. Then adjust receiver oscillator padding condenser for maximum output, RETURNING the set after each change in adjustment. Then increase test oscillator frequency to 1400 KC and carefully tune the set to this frequency. Then carefully adjust the "A", "B" and "O" trimmers for maximum output.

The following should be of interest in connection with the Models 203 and 204 speakers used in the present line of receivers. A high temperature developed by the field coil is not a sign of a defect. This is true even if the housing becomes too hot to touch, providing of course that the speaker is functioning in normal manner. This design is deliberate and proper provision has been made to safeguard against injury of the windings.

RADIO SERVICE NOTES (R-101 & 102)REPLACING POWER TRANSFORMERS

When replacing power transformers in Model 101 or 102 Radio Receivers, the following precautions must be observed, or the transformer is almost certain to hum badly.

After mounting the transformer but prior to clamping it tightly in place, paint the edges of the steel core of the transformer with a liberal quantity of shellac or medium thick clear lacquer to act as a binder and prevent the individual laminations from rattling. Allow the shellac to dry for several minutes and then using a heavy screw driver, tighten down the bolts with as much force as you can exert. A light screw driver will not enable you to tighten the bolts sufficiently. Do not omit the lock-washers under the screw-heads. Do not turn on the set until the binder has had a chance to dry, otherwise hum may not be eliminated.

When servicing a radio receiver in which the transformer hums, remove the two bolts holding it in position, thus loosening the transformer. It is not necessary to unsolder the leads. Drive in the wedge which you will find on one side of the center leg of the core between the core and coil. This tightens the center portion of the core and prevents it from vibrating. Now paint the transformer core liberally with shellac, insulating varnish, or medium thick clear lacquer, and replace as directed above.

For humming filament transformers in Model 301 receivers, remove the two screws holding the transformer to the set and pry off the U shaped metal clamp from about the steel core, taking care that you do not bend it out of shape. Paint the edges, with particular attention to the top I section, with a liberal quantity of shellac or lacquer as in the case of power transformers and replace the U shaped clamp. If necessary, bend in the side flaps of the clamp so that they press the individual laminations together more firmly.

REPAIRING SHORT WAVE CONVERTERS HAVING POOR VOLUME

Occasionally a short wave converter may be found which is very insensitive even though all circuits check perfectly and the tubes are in good condition.

Converters of this type may frequently be made to operate satisfactorily by RESOLDERING EVERY SOLDERED CONNECTION IN THE CONVERTER, even though these connections may appear to be entirely satisfactory.

A poorly soldered connection may have sufficiently high resistance to materially affect performance on short waves, yet not high enough to show up on a simple continuity test.

NOTES ON SHORT WAVE CONVERTER

When connecting the Stewart Warner 301 A short wave converter to any receiver other than the 102-A, the following points must be borne in mind.

The plate supply plug must connect to a source of filtered DC inside the radio receiver that will deliver approximately 5 milliamperes at 100 to 280 volts although the recommended plate voltage is 250 volts. If it drops below 180 volts the '27 oscillator tube may not oscillate at the higher frequencies. If it rises above 280 volts parasitic oscillations may be produced.

In tube broadcast receivers in which the speaker field is in the positive side of the plate supply, a connection to the high voltage side of the speaker

field will usually provide a satisfactory source of plate potential.

When the speaker field and filter choke are in the negative side of the plate power supply, the correct positive potential for the short wave converter can frequently be taken off conveniently at the filament terminal of the 280 rectifier tube socket.

When tapping into the plate supply of any broadcast set, make certain that no resistors are being overloaded by the added drain of the converter. It is always safest to tap as close to the output of the filter as possible. Should this give excessively high voltage, it may be cut down to the correct value by means of a separate series resistor, capable of carrying 6 milliamperes safely. The value of this external resistor will be roughly 175 ohms for every volt in excess of 250. For example, if the B supply voltage is 350, a resistor of 17,500 ohms will be required to reduce it to 250 volts, which is the recommended value.

As a check on the correct voltage, the plate voltages at the tube sockets of the converter may be measured. The '27 tube plate should be kept about 90 volts when in normal operating condition. It should never drop below 70 volts or rise about 105 volts. The attached circuit data sheet gives plate voltage as measured with a high resistance voltmeter, of both tubes at input voltages of 180, 250 and 280.

The negative return of the Converter B supply is made thru its ground binding post to the broadcast receiver ground which, in a great majority of A.C. receivers, is at B negative potential. However, there are some sets on the market in which the negative B supply does not connect to the chassis. When the Model 301-A converter is to be used with sets of this type, the ground binding post of the converter must not be connected to ground but to the negative of the B supply system at a point inside the broadcast set. The broadcast set should be grounded in the usual way.

The plate supply lead of the converter should never go direct to a plate terminal of the broadcast set, since this may result in detuning and objectionable regeneration in the broadcast receiver.

The following advice should also be of interest:

- "Don't tune above 33 meters for distant stations in daylight.
- "Don't tune below 25 meters for distant stations after dark.
- "Don't expect to hear many distant stations above 50 meters.
- "Don't skim over the dials. Tune slowly.
- "Don't expect to find stations on all parts of the dials. Short wave stations are widely separated except in a very few places.
- "Don't expect stations to tune broadly. Distant stations tune very sharply.

L ₂₃	Secondary of Power Transformer for Output Tube Filaments	
L ₂₄	Secondary of Power Transformer for Plates of Rectifier Tube	
L ₂₅	Secondary of Power Transformer for Rectifier Filament	
L ₂₆	First Ripple Filter Inductor	
L ₂₇	Second Ripple Filter Inductor	
L ₂₈	Speaker Field Winding	

TABLE II. RESISTOR IDENTIFICATION

Designation	Function	Value
R ₁	Grid Bias Feeder of Radio Amplifier	500 Ohms
R ₂	Filter Resistor Plate Circuit of Radio Amplifier	600 Ohms
R ₃	Grid Bias Feeder for Mixer of I. F. Amplifier	100,000 Ohms
R ₄	Grid Bias Feeder for Mixer Tube	500 Ohms
R ₅	Filter Resistor for Screen Circuits of Mixer and I. F. Amplifier	600 Ohms
R ₆	Filter Resistor for Demodulator Screen Circuit	10,000 Ohms
R ₇	Mid-tap Resistor Heater Circuit (at Mixer Tube)	3 Ohms
R ₈	Grid Bias Feeder for Demodulator	5 Megohms
R ₉	Grid Bias Feeder for Demodulator	100,000 Ohms
R ₁₀	Cathode Resistor of Demodulator Tube	20,000 Ohms

TABLE II. RESISTOR IDENTIFICATION—Continued

Designation	Function	Value
R ₁₁	Shunt Resistor for Primary of Push-Pull Input Transformer	250,000 Ohms
R ₁₂	Hum Balancer Potentiometer	400 Ohms
R ₁₃	Grid Biasing Resistor at Power Output Tube	750 Ohms
R ₁₄	Mid-Tap Resistor of Filament Circuit of Output Tube	10 Ohms
R ₁₅	Volume Control Potentiometer	1,000 Ohms
R ₁₆	Filter Resistor for Grid Bias Circuits	100,000 Ohms (10,000 Ohms 25 Cycles)
R ₁₇	Filter Resistor of Screen Circuits, 25 Cycles Only	40,000 Ohms
R ₁₈	Series Grid Resistor of Oscillator	500 Ohms
R ₁₉	Cathode Resistor of Mixer Tube	10,000 Ohms
R ₂₀	Cathode Resistor of Oscillator Tube	6,500 Ohms
R ₂₁	Auxiliary Voltage Divider Resistor	350 Ohms
R ₂₂	Section of Voltage Divider Resistor	780 Ohms
R ₂₃	Section of Voltage Divider Resistor	100 Ohms
R ₂₄	Section of Voltage Divider Resistor	8,900 Ohms
R ₂₅	Section of Voltage Divider Resistor	3,200 Ohms
R ₂₆	Section of Voltage Divider Resistor	4,760 Ohms
R ₂₇	Filter Resistor of Demodulator Plate Circuit	40,000 Ohms

TABLE III. CAPACITOR IDENTIFICATION

Designation	Function	Value
C ₁	Range Control Capacitor	.015 Mf.
C ₂	"Long Antenna" Aligning Capacitor	
C ₃	"Short Antenna" Aligning Capacitor	
C ₄	Unit of Variable Gang Capacitor	400 Minf. Max.
C ₅	Unit of Variable Gang Capacitor	400 Minf. Max.

Model 29 (1932)

The Stromberg-Carlson No. 29 Radio Receiver is a Superheterodyne employing nine tubes. An improved Automatic Volume Control circuit with Visual Tuning Meter is incorporated.

Four No. 235 tubes are used as R. F. Amplifier, Mixer, I. F. Amplifier, and First Audio Amplifier. Two No. 227 tubes are used as Oscillator and Demodulator-AVC. Two No. 245 tubes are used in the push-pull output stage. A No. 280 Rectifier is used in the power supply.

A Bi-resonator is used to couple the antenna to the R. F. amplifier to prevent any cross modulation. The R. F. amplifier is coupled to the mixer by an ordinary tuned R. F. transformer. This gives three tuning circuits (four gang tuning capacitor) for R. F. selectivity ahead of the mixer, thus the image response ratio is exceedingly high. The oscillator is coupled to the cathode circuit of the mixer tube in the regular manner. The I. F. output of the mixer tube is fed into a Tri-resonator (three tuned circuit transformer) and thence to the I. F. amplifier tube. This tube is coupled to the duo-diode demodulator-AVC tube by a choke-tuned circuit arrangement. The audio output of the duo-diode is fed through a radio frequency filter to the resistor unit of the Manual Volume Control which acts as a coupling resistor to the audio amplifier. The A. V. C. voltages from the other diode circuit are led back to the control grids of the first two tubes. A No. 235 screen grid tube is used in the first audio stage to obtain high amplification without distortion.

NORMAL VOLTAGE READINGS

These voltage readings correspond to a line voltage at 120 volts with the fuse in the "HI" position or 110 volts in the "LO" position. The fuse should be set in the proper position for the line voltage obtained before making measurements. When voltages are measured proper allowance should be made for a difference in line voltage above or below 110 or 120 volts. Be sure to make these readings with the Meter and Scale indicated, otherwise the results will not agree with those tabulated. Alternating voltages are indicated by italics.

Voltage	Meter	Scale	Where Measured	Approx. Value in Volts
Heater Voltages No. 227 and No. 228 Tubes	A. C.	0-4	Across Heater Terminals of Sockets	2.60
Filament Voltage No. 26A Tubes	A. C.	0-4	Across Filament of Audio Output Socket	2.60
Plate Voltage Radio Amplifiers	D. C.	0-250	Between Plate Terminal of R. F. Amplifier Socket (+) and Chassis Base	170

ELECTRICAL SPECIFICATIONS

Type of Circuit	Superheterodyne
Type and Number of Tubes	4 No. 58, 2 No. 56, 2 No. 45, 1 No. 80
Voltage Rating	105-125 volts
Frequency Rating	60 cycles and 25-60 cycles
Power Consumption	110 watts
Undistorted Electrical Power Output of Chassis	3.2 watts

CIRCUIT DESCRIPTION

The four No. 58 triple-grid tubes are used as R. F. Amplifier, Mixer, I. F. Amplifier, and Demodulator-AVC. The two No. 56 tubes are used as Oscillator and First Audio Amplifier. The two No. 45 tubes are used in the push-pull output stage. The No. 80 is used as the rectifier in the power supply.

A Bi-resonator is used to couple the antenna to the R. F. amplifier to prevent any cross modulation. The R. F. amplifier is coupled to the mixer by an ordinary tuned R. F. transformer. This gives three tuning circuits (four gang tuning capacitor) for R. F. selectivity ahead of the mixer, thus the image response ratio is exceedingly high. The oscillator is coupled to the cathode circuit of the mixer tube in the regular manner. The I. F. output of the mixer tube is fed into a Tri-resonator (three tuned circuit transformer) and thence to the I. F. amplifier tube. This tube is coupled to the diode-triode demodulator-AVC tube by a single tuned circuit transformer.

The load resistor of the diode portion of the diode-triode forms the resistor unit of the first potentiometer of the dual volume control. The AVC voltage and the rectified audio signal are built up across this resistor. The AVC voltage is fed back to the grids of the first two tubes through a suitable filter. The audio voltage is applied to the control grid of the triode portion of this system through the movable contact of the potentiometer. The screen of the tube acts as the plate of the triode portion of the system, thus forming the triode audio amplifier in conjunction with the diode rectifier.

The output of this "plate" circuit is coupled to the second unit of the dual volume control which feeds the grid of the first audio tube. The output of this first audio stage is coupled to the push-pull output triodes. The Adjustable Automatic Clarifier system is connected across the primary of the push-pull input transformer. The output transformer feeds the signal from the power triodes to the high quality electro-dynamic speaker.

The power supply system employs two stages of filter; the first being of the resistance type, and the second using the field of the speaker as a choke. The plate supply for the output tubes is tapped off between these filter sections, while the remainder of the voltages are supplied from the voltage divider resistor.

MODEL AC84,85
Schematic
Voltage

Model AC84 & AC85 receivers are designed for operation on 110 to 120 volt 50 to 60 cycle alternating current. The models 25-84 & 25-85 are to be operated on 110 to 120 volts 25 to 40 cycle alternating current only.

In the Model 84 & 85 receivers power is turned on by turning the right hand knob over to the right. Tone is controlled by turning the same knob continuously over to the right. The bass position being reached when the control is all the way over. Treble tone is obtained by turning the knob back over to the left. Volume is controlled by turning the left hand knob.

PEAK
FREQUENCY
175. KC.

READJUSTING TRIMMERS

To readjust the trimmers on these super-heterodyne receivers it will be necessary that a good design of 175 k.c. oscillator be employed and that a dependable broadcast test oscillator be on hand so that stages handling intermediate frequency and those handling radio frequency can be thoroughly checked. It is advisable to use a bakelite screw driver when making any of these adjustments.

First, connect the 175 k.c. oscillator output leads from the control grid cap of the first detector tube to ground. Do not remove any of the tubes from the sockets, and it is not necessary to disconnect the grid cap clip from the first detector tube. Reset trimmers No. 5, No. 6, No. 7 and No. 8 for maximum output. While this test oscillator is working into the intermediate frequency stages, no adjustment of the tuning condenser on the receiver will have any effect, inasmuch as the intermediate frequency stage is fixed tuned.

If your test oscillator is properly designed, it will supply exactly 175 k.c., and when trimmers No. 5, No. 6, No. 7 and No. 8 are set and turned for maximum output, they will be correctly adjusted.

Next, disconnect the 175 k.c. test oscillator and connect to the antenna binding post of the receiver, the output lead from your broadcast test oscillator or tune in a broadcast signal around 1400 k.c., then reset trimmer No. 2 and No. 1, respectively, for maximum output. This adjustment will track the first detector and r. f. stages.

To check calibration of the receiver, whether it be high or low, trimmer No. 3 (oscillator) should be reset until a station of known high frequency is brought in at the correct dial marking with peak volume. If your broadcast test oscillator is accurately calibrated, it might be used in place of the broadcasting station signal. In this adjustment, a broadcast station or test oscillator signal at about 1400 k.c. should be chosen. The setting of the trimmer at 1400 k.c. is more critical than it would be at 600 k.c.

The next adjustment is important and not easily explained in writing, so pay close attention to the following instructions. We will now balance the oscillator to the r. f. and first detector stages.

Tune the external broadcast test oscillator and the receiver both to 600 k.c., then slowly increase or decrease the capacity of No. 4 (oscillator padding trimmer), at the same time and continuously tuning back and forth across the signal with the receiver tuning condenser gang. The output meter needle will now be swinging up and down in step with the variation in tuning. Watch the peak of this swinging closely and readjust No. 4 trimmer until the swinging needle reaches its highest peak.

Retune the receiver and broadcast test oscillator to 1400 k.c. and re-check trimmer No. 3 to make sure that the adjustment of No. 4 has not thrown the receiver out of calibration. If it has, then readjust No. 3 until the calibration is correct, (as previously explained), and check on trimmers No. 2 and No. 1, to make sure that the adjustment of No. 4 has not reduced the sensitivity.

CONTINUITY TESTS

(Applicable to completely and partially in-operative sets and circuits)

A 175 k.c. test oscillator should be connected to the grid cap of the first detector tube so that the modulated signal can be reproduced in the loud speaker. This indicates that the first detector and intermediate frequency stages are operating. To determine if the oscillator is working, a broadcast test oscillator should be connected to the grid cap of the first detector tube. No signal will come through unless the oscillator tube and stage are functioning correctly. The r. f. tube, of course, can be checked lastly by connecting the broadcast test oscillator to the antenna and ground binding posts of the receiver.

MODEL AC-94, 25-94
 TRANSFORMER CORP. OF AMERICA Schematic - Voltage

Model AC-94 receivers are designed for operation on 110 to 120 volt, 50 to 60 cycle alternating current. The Models 25-94 are to be operated on 110 to 120 volts, 25 to 40 cycle alternating current only.

TRANSFORMER CORP. OF AMERICA

CLARION SERIES 100 SUPERHETERODYNE

CONTINUITY TESTS

Applicable to Completely and Partially In-Operative Sets and Circuits)

To determine which section of the receiver is defective, the second detector tube might be tapped with the finger, listening for a ringing noise in the speaker—this indicates that the audio end is O. K. A 175 K. C. test oscillator should be connected to the grid cap of the Super-autodyne tube so that the modulated signal can be reproduced in the loud speaker. This indicates that the Super-autodyne and intermediate frequency stages are operating. To determine if the super-autodyne is oscillating as it should be, a broadcast test oscillator should be connected to the grid cap of the super-autodyne tube. No signal will come through unless the tube is oscillating, and the stage functioning correctly. The R. F. tube, of course, can be checked, lastly by connecting the broadcast test oscillator to the antenna and ground binding posts of the receiver.

MODEL AC 100 Series
Trimmer Notes

TRANSFORMER CORP. OF AMERICA

CLARION SERIES 100 SUPERHETERODYNE

READJUSTING TRIMMERS

Number 1 is the antenna trimmer.

Number 2 is the gang condenser trimmer tuning the grid of the Super-autodyne.

Number 3 is the gang condenser trimmer tuning the plate (or oscillator of the super-autodyne).

Number 4 is the oscillator padding trimmer.

Number 5 is the Super-autodyne plate trimmer.

Number 6 is the I. F. grid trimmer.

Number 7 is the second detector grid trimmer.

To readjust the trimmer, it will be necessary that a good design of 175 k. c. oscillator be employed, and that a dependable broadcast test oscillator be on hand so that stages handling intermediate frequency, and those handling radio frequency can be thoroughly checked. It is advisable to use a bakelite screwdriver when making any of these adjustments.

First, connect the 175 k. c. oscillator output leads from the control grid cap of the super-autodyne tube to ground. Do not remove any of the tubes from the sockets, and it is not necessary to disconnect the grid cap clip from the tube. Reset trimmers numbers 5, 6 and 7 for maximum output. While this test oscillator is working into the intermediate fre-

quency stages, no adjustment of the tuning condenser on the receiver will have any effect, inasmuch as the intermediate frequency stage is fixed tuned.

If your test oscillator is properly designed, it will supply exactly 175 k. c., and when trimmers number 5, 6 and 7 are set for maximum output, they will be correctly adjusted and should be sealed.

Next, disconnect the 175 k. c. test oscillator and connect to the antenna binding post of the receiver, the output lead from your broadcast test oscillator, or tune in a broadcast signal around 1400 k. c., then reset trimmers numbers 2 and 1 respectively for maximum output. This adjustment will track the super-autodyne grid circuit of the R. F. stage.

To check the calibration of the receiver, whether it be high or low, trimmer number 3 should be reset until a station of known high frequency is brought in on the correct dial marking with peak volume. If your broadcast test oscillator is accurately calibrated, it might be used in place of the broadcasting station signal. In this adjustment, a broadcast station or test oscillator signal at about 1400 k. c. should be chosen. The setting of the trimmer at 1400 k. c. is more critical than it would be at 600 k. c.; calibration therefore more accurate.

The next adjustment is important and not easily explained in writing, so pay close attention to the following instruction. We will now balance the oscillator to the r. f. and first detector stages.

Tune the external broadcast test oscillator and the receiver both to 600 k.c., then slowly increase or decrease the capacity of No. 4 (oscillator padding trimmer), at the same time and continuously tuning back and forth across the signal with the receiver tuning condenser gang. The output meter needle will now be swinging up and down in step with the variation in tuning. Watch the peak of this swinging closely and readjust No. 4 trimmer until the swinging needle reaches its highest peak.

Retune the receiver and broadcast test oscillator to 1400 k.c. and re-check trimmer No. 3 to make sure that the adjustment of No. 4 has not thrown the receiver out of calibration. If it has, then readjust No. 3 until the calibration is correct, (as previously explained), and check on trimmers No. 2 and No. 1, to make sure that the adjustment of No. 4 has not reduced the sensitivity.

UNITED AMERICAN BOSCH CORP.

Antenna Adjustment—The antenna adjustment must be made when any change is made in the antenna.

Alignment Instruction

1. Connect the 175 KC output of the oscillator to the grid cap of the 1st detector.
 - a—Align Primary of 2nd IF Transformer (C9).
 - b—Align Secondary of 2nd IF Transformer (C10).
 - c—Align Primary of 1st IF Transformer (C7).
 - d—Align Secondary of 1st IF Transformer (C8).

(It is advisable to go over these adjustments twice to insure accuracy).

2. Reset the Oscillator for 1400 KC, connected to the 1st detector grid as before.
 - a—Align the Oscillator tuning condenser C6 by unscrewing two full turns, then turning slowly to the right until the first peak is reached.
3. Connect the 1400 KC output to the Antenna Connection of the set.
 - a—Align Antenna Trimmer and 1st detector C3.

Alignment Adjustments

4. Retune the receiver to 600 KC and set oscillator to this frequency.
 - a—Align the oscillator low frequency adjustment C11. Rotate the dial slowly back and forth over a range of perhaps 1/4", at the same time rotating C11 back and forth until the maximum output is reached.
5. Return to 1400 KC (Receiver and Oscillator).
 - a—Re-align C3, C6 and the Antenna Trimmer.

UNITED AMERICAN BOSCH CORP.

MODEL 31, 32
Schematic
Data - Socket

Antenna Adjustment—The antenna knob, located as shown on the drawing (figure 1) is for the purpose of obtaining the most efficient adjustment of the receiver to the antenna. Simply tune in a semi-distant broadcast station at reduced volume and turn the adjustment knob until the point of loudest reception is found. Select if possible a station received near 140 on the dial. The adjustment is permanent, and need not be disturbed unless the antenna is changed.

Line Voltage—The model 31 receiver is designed for use on 50 to 60 cycle alternating current, 105 to 120 volts. The model 32 is designed for 25 to 50 cycle, 105 to 120 volt alternating current. If excessive line voltage is encountered, some type of series resistance or "voltage regulator" should be employed.

Tone Control—The tone is varied from treble to bass by means of a two position snap switch operated by the right hand knob. The range of motion of this switch has been reduced from that found on previous models and care should be taken not to force the switch beyond the stop position.

Main Power Transformer

The various transformer windings may be identified for testing purposes as follows: Four leads are brought out on the terminal strip side and five on the opposite side.

Primary Winding—two terminal strip terminals nearest rear of set.

551, 224, 227 Filaments—heavy wires, terminal strip side.

Plate Center Tap—terminal nearest front of set.

280 Plates—stranded wires, opposite side.

280 Filaments—solid wires, opposite side.

Resistors

The resistors used in the models 31 and 32 receivers conform to the RMA standard of marking and may be identified by the following table of value and colors

Value	Body Color	Tip Color	Dat Color
300 ohms	Orange	Black	Brown
350 "	Orange	Green	Brown
1000 "	Brown	Black	Red
5000 "	Green	Black	Red
10000 "	Brown	Black	Orange
20000 "	Red	Black	Orange
30000 "	Orange	Black	Orange
50000 "	Green	Black	Orange
100000 "	Brown	Black	Yellow
1/2 megohm	Green	Black	Yellow
1 megohm	Brown	Black	Green
2 megohm	Red	Black	Green

ALIGNMENT

The following instructions for the alignment of the condensers in the models 31 and 32 describe the operation as done with any type of special oscillator designed for the adjustment of superheterodyne receivers. Such an oscillator is essential for anyone who handles more than a small amount of service work. Such oscillators are designed to provide ordinary broadcast frequencies, and in addition, a 175 kilocycle for the alignment of the intermediate frequency (I. F.) stages.

Alignment Instructions:

1—With 175 KC on the grid of the 551 IF tube Align C9

2—With 175 KC on the grid of the 551 1st detector Align C7, C8 and re-check C9

Set the condenser gang at the maximum position and move the dial until the line of light indicator is 1/4" to the right of the 55 division.

3—With 1400 KC on the grid of the 551 1st detector Align C6

4—Set gang at 600 KC and with 600 KC input on grid of 1st detector

Align C10

Re-check as in 3 above.

5—Set gang at 1400 KC with input on antenna connection

Align C1 and C5

Main Filter Condenser

The main filter condenser unit contains buffer condenser C26, by-pass condensers C27 and C29, and condenser C28 which "tunes" the speaker field coil. The unit is connected as follows:

- Red lead —Speaker plug socket (see wiring diagram)
- Green lead—"F" terminal of 280 socket
- Blue lead —110 volt terminal at main transformer
- Black lead—to R15 (350 ohms) on resistor strip

- Test C27 from Black to Green
- Test C28 from Green to Red
- Test C29 from Red to Ground
- Test C26 from Blue to Ground

MODELS 31-32 Superheterodyne

**MODEL 80
Installation
Notes**

UNITED AMERICAN BOSCH CORP.

Capacitor Plate:

In Figure 5 is shown the means by which this plate is supported underneath the chassis of the automobile. The insulation has been very carefully considered and is so designed that it is unaffected by mud, water, or dust. A location on either side of the car frame or one across the rear, parallel to the axle, will be satisfactory. The plate is adjustable and it is desirable that it be lengthened as much as is possible without interfering with the mechanism of the car. Do not, however, bring the plate too near the motor compartment. Make sure that the clamping nut of the capacitor plate supporting bolt is tightened before fastening the clamp in place on the car frame with the pointed screw. The clamping nut, besides locking the supporting bolt, also serves to reinforce the "C" clamp against any tendency to open. Complete the installation by tightening the set screw and lock nut. The capacitor plate must be mounted as low as possible without interfering with the road clearance, and not too closely to large metal objects, such as "B" battery box, muffler, or car frame.

Fig. 5—Capacitor Plate.

Chassis:

The chassis mounting is a rigid frame "D" having two adjustable brackets, "C" to support it against the dash board. Refer to Figure 2. In the installation of the set these brackets are assembled and the frame work used as a template to locate the holes in the dash board for the holding bolts. The bracket must be so located that clearance will be obtained for all obstructions. On the engine side, care should be taken to avoid interference with the vacuum tank or other devices mounted there. In using this bracket as a template, do not fail to use the radio set as a guide to obtain clearance for the projection of the set and for the control shaft and the battery cable. Drill the holes as located, using a 5/16" diameter drill in order that unavoidable irregularities in the location of the holes may be taken care of when the set is screwed in place. Next, mount the chassis on its rubber cushions and secure the entire assembly in position. Drive the holding bolts from the front and pull the set securely in place. In some cases, where the dash-board is free of all obstructions, it is possible to dispense with the brackets "C" and bolt the mounting frame directly against the engine bulkhead. This type of installation provides slightly more leg room. The frame is used as a template for laying out the mounting holes as before.

Capacitor Coupler:

This unit must be mounted at the nearest convenient point to the capacitor plate. The mounting bracket is permanently fastened to the coupler and it is only necessary to bolt the bracket to the car frame. See Figure 6.

The coupler is provided with two connecting leads. The red lead should be cut to a length just sufficient to reach the capacitor plate and the spade terminal (which is shipped loosely clipped to the wire) soldered to the

Fig. 6—Coupler.

end. Connection is made at the capacitor plate by means of a terminal screw and clip.

The shielded lead from the receiver must be tightly clamped in the cable clamp provided on the coupler unit. Connect the wire in the shielded lead to the black wire from the coupler and carefully solder and tape the joint. Be careful that the woven shielding is effectively grounded through the clamp provided on the coupler, and is kept back from the joint in order to prevent a short circuit.

Data

UNITED AMERICAN BOSCH CORP.

MODEL 100 SUPERHETERODYNE
MOTOR CAR RADIO

This is a seven tube, superheterodyne receiver with full automatic volume control, push-pull pentode output and electro dynamic speaker. The Magmotor, a source of "B" current, is supplied as an accessory.

TUBES are furnished with receiver as follows:

- | | |
|---|---|
| 1 type 236, radio frequency amplifier. | 1 type 238, diode triode which functions as a second detector, and audio-amplifier, and with its related circuit, furnishes voltage for automatic volume control. |
| 1 type 237, oscillator. | |
| 1 type 236, first detector. | |
| 1 type 236, intermediate frequency amplifier. | |
| 2 type 238, as push-pull audio amplifiers. | |

The type 238 tubes used in the last three positions named above, are pentode power output tubes. All of the tubes used in this receiver are designed especially for automobile use to withstand the vibration and heater voltage fluctuation to which they are subjected.

CHASSIS contains the tubes, tuning condensers and elements of the electrical circuit. (See circuit diagram). It is enclosed in a metal box provided with mounting hooks for easy attachment to a MOUNTING PLATE designed to be mounted either side of the bulkhead. Shielding is complete and internal filtering is so arranged that a minimum of engine interference obtains. Speaker, battery box, control head and plate antenna, find easy attachment to the chassis through cable plug connections inserted on the under side of chassis.

CONTROL UNIT fastens to the steering column and regulates the station selection and volume level. Cable is connected internally with plug for chassis connection.

FLEXIBLE SHAFT connects control unit and chassis drive. It consists of three layers of five strands of wire wound in alternate directions, enclosed in flexible tube: provides accurate tuning unaffected by excessive vibration.

LOUD SPEAKER of electro dynamic type consumes $1\frac{1}{2}$ amperes from storage battery. Cable is connected internally with plug for chassis connection.

MAGMOTOR using permanent magnet field delivers 40 M. A. of plate current at 160 volts (at the tubes) with an "A" battery drain of 2 amperes. Self-enclosed with filtering to eliminate brush interference. Cable connected internally with plug for chassis connection.

IGNITION SUPPRESSION is accomplished through use of 9 resistors in ignition circuits and grounding of cable shields.

BATTERY BOX of heavy weather proof steel, for optional use to contain 3 special Heavy Duty automobile type "B" batteries. Battery box hangs from floor boards of car, access from the top. Cable furnished with plug for chassis connection.

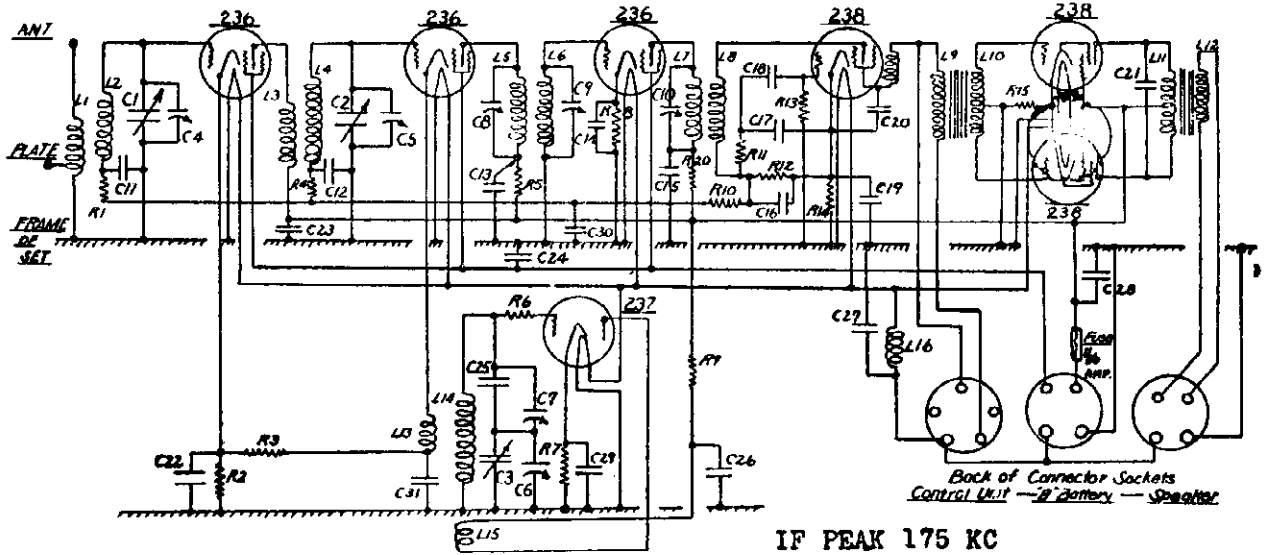

PLATE ANTENNA for optional use when there is no roof antenna in car: clamps to frame of car with hardened set screws. Step down transformer fastened to bracket; cable attached to plate with plug for chassis connection.

UNITED AMERICAN BOSCH CORP.

ADJUSTMENT OF THE RECEIVER.

After the receiver has been installed it is necessary to adjust it to the frequency of the transmitting station. Even if the set has been shipped with the proper setting, a slight readjustment will be necessary. The procedure is the same in both cases.

The positions of the four alignment condensers which take care of the adjustment are shown on the installation drawing. The car should be in the vicinity of the transmitting station when the alignment is made, in order to assure adequate signal strength. Proceed as follows:

1. Switch the receiver "on" and turn the volume and sensitivity control to maximum position.
2. Adjust OSCILLATOR condenser until the signal is picked up, using a special screw driver with an insulated tip. (Such an American Bosch Service Tool #432).
3. Reduce the sensitivity control until the station can just be heard, and re-adjust the OSCILLATOR until the signal is loudest.
4. Reduce the sensitivity control until the station can just be heard and adjust the HF alignment for maximum volume. As the volume increases, reduce the sensitivity as far as possible. This permits a sharper adjustment to be made, as the ear is more sensitive to changes in volume when the signal is faint.
5. Screw the SERIES antenna condenser in as far as possible. Pay no attention to the signal while doing this.
6. Attempt to find a position of the SHUNT condenser which will give maximum volume. Always reduce the sensitivity control when increased response of the set results from the various adjustments which you are making.
7. If no position of the SHUNT condenser will give a point of maximum volume or "peak", unscrew it as far as possible and slowly unscrew the SERIES condenser until the adjustment is obtained. Endeavor to obtain this adjustment with the SERIES condenser screwed IN as far as possible.

The relative position of the shunt condenser is unimportant.

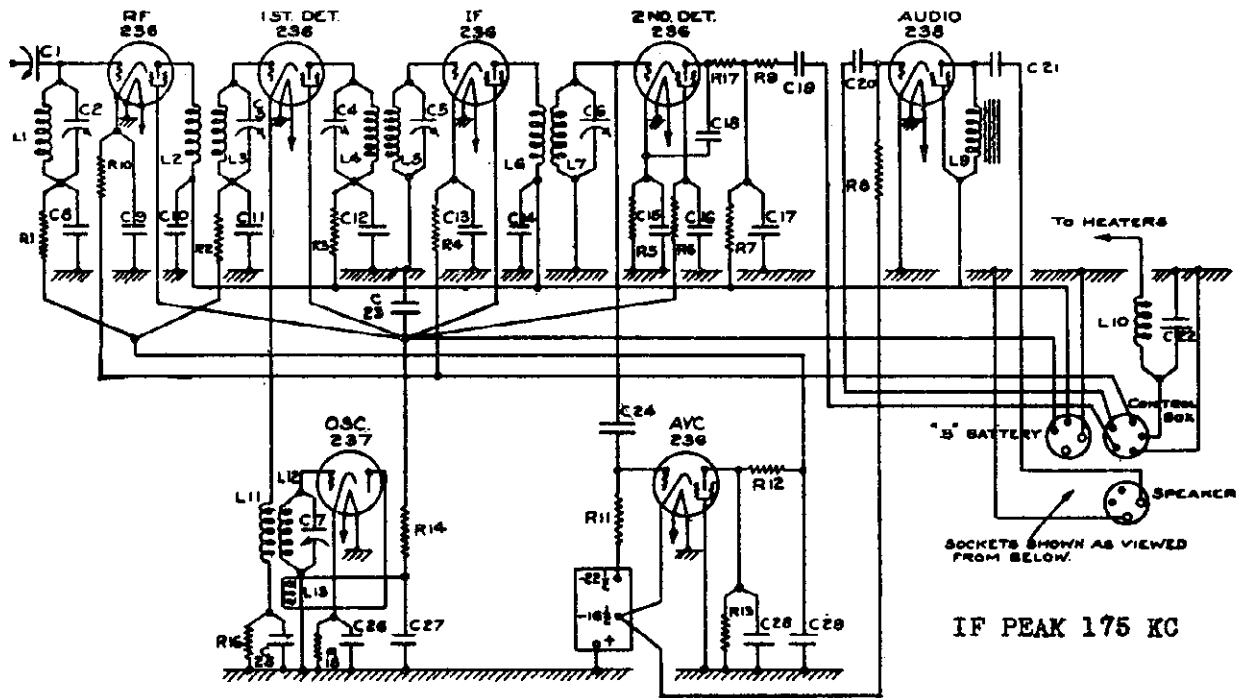

FUSES

A 1/16 ampere fuse is located in the B Battery jumper wire, as described under "B" Battery Cable". The "A" fuse is located in the control box and may be reached for replacement by simply removing the cover.

Rect.	280	4.8	Plate current of each plate · 20				

The readings were made with the volume control in the full "on" position.

*These voltages are the correct values. The average test kit will give much lower readings, (as low as 1/10 of these values) due to the low resistance of the meters compared to the high resistance included in the detector plate and screen circuits and the audio grid circuit.

IMPORTANT

Antenna Adjustment: The small knob located on the loud speaker must be adjusted at the time of installation to obtain the best reception. Make this adjustment on a weak station which is received at some point near 30 on the dial and then re-check the adjustment at several other points to make sure that it has been accurately done.

Chassis: The chassis may be removed by pulling off the knobs and unscrewing the felt feet.

MODEL 312,313
Adjustments

UNITED AMERICAN BOSCH CORP.

TEST OF SENSITIVITY ON MODEL #312

NOTE While making adjustments on chassis make sure that the signal does not overload any of the tubes, otherwise incorrect adjustment will result.

I. F. ADJUSTMENT

- a. Set volume control on max. tone control on treble and ground antenna lead.
- b. Connect the 175 Kc. I.F. signal generator to the grid of the 1st. det.
- c. Align secondary of 3rd I.F. transformer for max. output.
- d. With the lossor on the grid of the 2nd I.F. tube, adjust condenser on primary (front one) of 2nd I.F. coil. (e) Holding the lossor on the plate side of 2nd I.F. coil, adjust the condenser on secondary (rear one) of 2nd I.F. coil.
- f. With the lossor on the grid of the 1st I.F. coil, adjust the condenser on secondary (front one) of 1st I.F. coil. (g) Holding the lossor on the plate side of the 1st I.F. coil, adjust the condenser on secondary (rear one) of 1st. I.F. coil.
- h. Check sensitivity of I.F. Sensitivity limits are 200 mv. on 1st. det. grid. 700 - 312 on 1st I.F. grid. 18,000 on 2nd I.F. grid.

OSCILLATOR ADJUSTMENT

- a. Adjust pointer to mark past 550 Kc. (b) Connect ant. lead of the R.F. signal generator to grid of 1st. det. (c) Set the microvolter dial at 1400 Kc.
- d. Adjust oscillator alignment condenser until max. output is obtained.

NOTE When adjusting the oscillator 2 peaks may be obtained. Set the align. condenser down tight; turn to the right, one peak at (1575 Kc.) will be noted about $\frac{1}{2}$ of a turn out. Set on the (1575 Kc.) peak, otherwise the oscillator will not track in the center of the scale. (e) Connect ant. lead to microvolter. DO NOT TOUCH OSCILLATOR CONDENSER.

- f. Adjust antenna, R.F. and detector alignment condensers for max. output.
- g. Set the signal generator dial to 600 Kc. and pointer of the chassis to 600.
- h. Adjust the condenser on the oscillator coil (on side of chassis) until max. output is obtained and note sensitivity.

NOTE Disregard the pointer reading entirely during this adjustment. This is best obtained by adjusting the trimmer, retune & noting the output, then readjust & retuning until maximum output is obtained.

R. F. ADJUSTMENT

- a. Set the dials at 1400 Kc. and readjust all trimmers peaking oscillator condenser first; note sensitivity at 1400, 1000, 700, 550.
limits are 7 3 3 5.
- b. Check switch, volume control action and tone control. (c) Check power output. Should be 5 volts. (d) Check for hum, note any distortion while making tests.
- e. Check A.V.C. action by tuning meter. Should A.V.C. at 40 mv.
- f. Tap the 2nd. det. tube & check noise. (g) Check relay at 954 Kc. with control at maximum. It should release at 300 mv.

AIR TEST

- a. Connect ant. lead to outdoor ant. (b) Check for tone quality and carrier hum
- c. Check for selectivity & stability. (d) Check vol. control action & switch. (e) Check for power output. Should be ___ volts 10 watts. (f) Check for noise with ant. grounded.

**MODEL 7
Alignment
Voltage
Data**

U. S. RADIO & TELEVISION CORP.

Condenser Alignment

Aligning Intermediate Condensers—First align the screw driver is preferable for this. Adjust the signal generator for a signal of 282 K.C. The location knob should be at the normal position as explained in the section on this control or else it may be turned to the extreme counterclockwise position. One of the best ways of reading the output is by means of a rectifier type meter. This meter, if of low range, is connected across the secondary of the output transformer in series with a large condenser to prevent the flow of D.C. plate current through the meter. In either method of connection, opening the voice coil of the speaker will give a better deflection on the output meter.

Remove the grid cap from the grid connection of the 224 1st detector tube and connect the lead from the signal generator to the grid of the 224 1st detector. The tube shield should be on end of the chassis grounded. One way to make this connection is to bring the antenna lead from the signal generator through the place in the shield through which the grid wire passes. A grid cap on the end of the antenna lead of the signal generator will facilitate making this connection. This lead, of course, should be insulated. Another way of making this connection is to cut a hole of about 1" diameter in No. 7 chassis tube shield about 1" diameter in No. 7 chassis tube shield lead can then be passed through this hole to the grid connection of the 224 tube. Connect the ground lead of the signal generator to the ground post of the chassis.

The oscillator coil must be shorted out by grounding the lead from the tap on the secondary. This can be done conveniently by connecting a jumper from ground to the lug on the 3,200 ohm resistor at the end which connects to the oscillator.

The intermediate condenser adjusting screws are reached from the bottom of the chassis. There are two on the porcelain base of the oscillator and one on the porcelain base of the 2nd I.F. transformer assembly, Part No. 3571 and one on the porcelain base of the 2nd I.F. transformer assembly, Part No. 3544. The volume control should be at maximum setting. Attenuate the signal from the signal generator until the output is 75 volts or less in order to prevent any action of the A.V.C. Then adjust the three intermediate condenser screws until maximum output is obtained on the output meter, keeping the output at 75 volts or less. After all three have been adjusted the first time, go over them again and check the setting for maximum output.

Aligning R.F. and Oscillator Condensers—For adjusting the R.F. and oscillator condensers the signal input from the signal generator should be made to the antenna post. Adjust the signal generator for a signal of exactly 1400 K.C. Then turn the tuning condenser rotor until the pointer is at exactly 1400 on the dial scale. Then adjust the three trimmers on the tuning condenser for maximum output adjusting the oscillator trimmer first (trimmer nearest back of chassis). Turn the screws up or down until greatest deflection on output indicating meter is obtained. Keep the output below 75 volts as explained above.

The next step is to adjust the oscillator 600 K.C. trimmer condenser. The adjusting screw for this condenser is reached from the top of the

chassis and is located just in front and to the side of the 1st I.F. and oscillator assembly. Adjust the signal generator for a signal of 600 K.C. and turn the tuning condenser rotor until the output is at maximum. To correctly adjust this oscillator 600 K.C. trimmer it will be necessary to turn the screw to several different positions, using a nonmetallic screw driver preferably. At every position of this adjusting screw turn the tuning condenser rotor until maximum output is obtained. For each position of the adjusting screw there will be a maximum output and the correct position of the adjusting screw is the setting at which the deflection on output indicating meter is the greatest.

Next set the signal generator again for a 1400 K.C. signal and check the adjustment for tuning condenser trimmers at this frequency for maximum output. Then set the signal generator for a signal of 1000 K.C. and turn the tuning condenser rotor until the output indicating meter shows maximum deflection. Then bend the slotted rotor plate sections of the R.F. tuning condenser sections which are last in mesh. In or out until maximum output is obtained. In some instances it may be necessary to bend the oscillator condenser rotor plate sections also in order to get maximum output but this should be done only as the last resort as it tends to throw the dial calibration off. Tune in a signal at 750 K.C. and then at 600 K.C. and follow the same procedure bending the rotor plate sections last in mesh until maximum output is obtained. Do not change the setting of the oscillator 600 K.C. trimmer in any way after it has once been set as indicated above.

NOTE—In the No. 7 Receivers, starting approximately with Serial No. 1074054 the oscillator 600 K.C. trimmer is replaced by a condenser of fixed value and a different dial chart is used. The procedure for aligning the R.F. and oscillator condensers of these receivers is as follows:

Loosen the drive plate set screws and turn the tuning condenser rotor counterclockwise as far as it will go so that the rotor is completely in mesh. Turn the drive plate until the lowest frequency mark is directly under the dial pointer. Then lightly tighten one set screw.

Set the signal generator for a signal of 1400 K.C. and turn the drive plate until the 1400 K.C. mark is under the pointer. Adjust the three trimmer condensers at this frequency until maximum output is obtained, adjusting the oscillator trimmer first (trimmer nearest back of chassis).

Set the signal generator for a signal of 600 K.C. and tune the receiver exactly to this signal. Loosen the drive plate set screw and adjust dial drive scale. Then tighten the drive plate set screw lightly.

Set the signal generator again for a signal of 1400 K.C. and tune the receiver to this frequency. Readjust the trimmer condensers if necessary until the signal is received with maximum volume when the pointer is at 1400 on the dial chart.

Recheck the calibration at 600 K.C. for maximum output and if it is correct tighten both drive plate set screws firmly, care being taken that the rotor shaft does not slip.

Then set the signal generator for signals of 1000, 750 and 600 K.C. and check the two R.F. plate sections for resonance. Bend the slotted rotor plate sections last in mesh of these two banks until maximum output is obtained.

280	7	Rect.	4.9					39	Per Plate	

(1) This voltage read across 800 ohm resistor.
(2) Voltage as read with 600,000 ohm meter.
(3) Varies with setting of localizer. Voltages read with high resistance meter.
(4) Current zero with no signal and localizer at normal position.
(5) The voltage read across 200 ohm section of voltage divider.

SETTING THE LOCALIZER.

Turn the localizer knob counterclockwise as far as it will go. Then turn the knob one quarter turn clockwise. Next tune in a fairly strong signal and reduce the volume by means of the volume control knob on the front panel. Then turn the localizer knob to the extreme clockwise position. This will cause plate current cutoff in the RF and IF tubes. Then turn the knob slowly in a counterclockwise direction until the signal is again heard. With a slight additional turn in the same direction the signal builds up sharply to full strength and this is the correct position of the localizer setting. This adjustment should not be changed unless the set is reinstated or the tubes are changed. Incorrect adjustment of this knob will control the action of the AVC tube in such fashion that the automatic action will commence too soon or too late.

U. S. RADIO & TELEVISION CORP.

MODEL 7
Transformer
Data 25 cycle.

-Wiring Diagram, Osc. and I.F. Assembly

5 Section Condenser Internal Wiring

-Power Transformer Terminals

No. 7X Chassis—25 Cycle, 115 Volt

Chassis No. 7X is almost identical in construction with chassis No. 7, except that it is designed for 25 cycle, 115 volt operation. All parts as used in the No. 7 chassis are used in the No. 7X chassis with the exception of the power transformer, .1 Mfd. choke tuning condenser and 2 Mfd. electrolytic filter condenser. These items are replaced by a 25 cycle power transformer, .35 Mfd. choke tuning condenser and a 4 Mfd. electrolytic filter condenser. All of these items for the 25 cycle receiver are shown in the parts list.

The description and testing as covered in the No. 7 Service Notes also applies to the No. 7X.

Referring to Fig. 1 it will be noted that in the 60 cycle, No. 7 chassis the filter choke is tuned with a .1 Mfd. condenser. The purpose of this condenser is to tune the choke so as to offer maximum opposition to the 120 cycle ripple component. In the No. 7X chassis a .35 Mfd. condenser is used to tune the choke so as to offer maximum opposition to the 50 cycle ripple component which is present when 25 cycle power is used. Also in the No. 7X chassis there are three 4 Mfd. filter condensers used, while the No. 7, 60 cycle chassis uses two 4 Mfd. units and one 2 Mfd. unit.

The No. 7X, 25 cycle chassis can be operated satisfactorily from a 60 cycle power supply. If there is excessive hum it will be necessary to remove the .35 choke condenser and replace it with a .1 Mfd. choke condenser, Part No. 2927. The reverse is not true, that is, the No. 7, 60 cycle receiver cannot be operated satisfactorily from a 25 cycle power supply.

- ⁵ Across 550 ohm series resistor
- ⁶ Per Anode.

The No. 8X chassis is the same as the No. 8 except that it is intended for use on 25 cycle lines. The major difference is found in the power transformer and in the use of an untuned filter system. The .06 mfd condenser shown in the model 8 schematic connected across the filter choke is not employed in 8X. The 8X chassis may be used on a 60 cycle line. If the hum is bad, add the .06 mfd condenser.

For special service data see Heterodyne and Motorboating notes and RF, Oscillator and IF trimmer condenser data

U. S. RADIO & TELEVISION CORP.

DRWG. #3254. MODEL 10.

DOTTED LINES SHOWN ARE IN SPEAKER

No. 10 Series Super-Heterodyne

The No. 10X, 25 cycle chassis can be operated satisfactorily from a 60 cycle power supply. If there is excessive hum it will be necessary to secure a .06 Mfd. condenser, Part No. 2854, and connect it in the circuit across the filter choke. The reverse is not true, that is, the No. 10, 60 cycle receiver cannot be operated satisfactorily from a 25 cycle power supply.

Chassis No. 10X is almost identical in construction with chassis No. 10, except that it is designed for 25 cycle, 115 volt operation. All parts as used in the No. 10 chassis are used in the No. 10X with the exception of the power transformer and .06 Mfd. choke tuning condenser. The correct power transformer for the No. 10X chassis is shown in the parts price list.

 5 Across 600 ohm section of shunt resistor
 6 Per Anode.

Heterodyne Whistle

A heterodyne whistle in the Super-heterodyne Receiver may be caused by a beat between a harmonic of the I.F. signal and an R.F. signal.

A whistle can be brought about at 786 K.C., 1048 K.C. or 1310 K.C. if the 2nd detector filter choke is shorted or if the antenna lead is under this choke. The above mentioned frequencies are harmonics of the intermediate frequency of 262 K.C. and as they fall within the broadcast band can cause an audible beat with an R.F. signal.

A whistle can also be brought about between 540 and 600 K.C. if the I.F. tuning condensers are adjusted at too high a frequency rather than at 262 K.C. If they are adjusted, for example, at 280 K.C. the second harmonic is 560 K.C. which falls within the broadcast band and can beat with an R.F. signal.

Blocking or Motorboating

Blocking or motorboating in the No. 10 chassis may be due to an open grid in the 1st detector or I.F. stage. Check these circuits if motorboating is experienced. Motorboating may also be caused if the 10,000 ohm series resistor in the LF. and R.F. screen line is shorted.

If the A.V.C. tube is not operating properly motorboating may result. Try out a new tube and check the A.V.C. circuit. Blocking or motorboating may also be due to open R.F. and I.F. screen by-pass condenser and to various other defective filter and by-pass condensers.

Voltage

Notes

SPEAKERS

The output of the receiver is fed into the primary of the transformer for the speakers. In the chassis No. 1001 matched speakers are used. Both are D.C. baffle mounting electrodynamic speakers—one having a cone diameter of 10 inches and the other an 8 inch cone.

The fields of both speakers are energized by the power system and are a part of the total resistance shunted across the power system from which the required voltages are obtained. The 5000 ohm field coil is a component part of the 10 inch speaker—Part No. 3846—as is the output transformer. The 5000 ohm field coil is above ground potential whereas the 2000 ohm field coil is below ground potential, as can be seen by referring to Fig. 1. The ground potential side of each field coil winding is grounded to the speaker frame. The voice coil of each speaker is connected in parallel across the secondary winding of the output transformer.

CAUTION—Do not use any other type of speakers with the No. 1001 chassis than the two supplied with it. It can readily be appreciated from the above that the speakers are especially designed for this chassis.

An open or shorted voice coil in either of the speakers will cause poor audio quality. Check voice coil tips (blue and white) at speaker terminal strip for good electrical contact. A shorted 2000 ohm speaker coil will cause distortion as will also an open 5000 ohm speaker coil, and in both cases, the needle of the tuning meter will swing to the extreme left.

The polarity of the leads connecting the voice coils of the two speakers in parallel should be checked. If the blue and white wires making these connections are reversed, distortion and motorboating will result, because one cone is moving out while the other is moving in, and vice versa.

If one of the pilot light terminals is grounded, the second audio bias will be shorted out and there will be distortion present.

If the 2000 ohm field coil of the No. 3847 electrodynamic speaker is open lack of volume will be experienced and will be evidenced by the needle of the visual tuning meter, swinging almost to the extreme right. The same will be true if the 5000 ohm field of the No. 3846 electrodynamic speaker is open. However, in this case the needle of the tuning meter will swing to the extreme left. The yellow wire connecting the speakers to the chassis ground should be checked for good electrical connection. If this lead is making poor contact loss of volume will result. The tuning meter will register approximately a 50% reduction in swing at no signal.

MICROPHONIC HOWL

The No. 1001 Chassis is mounted in the console cabinet on sponge rubber washers to prevent any microphonic action that might otherwise arise due to vibrations set-up between the speaker and tube elements.

At the time of installation of the receiver the two bolts, one at the center of the flange at each end of the chassis should be removed. These bolts are used to securely anchor the chassis to the cabinet shelf and are intended only for shipping purposes. If they are not removed vibrations of the speaker will be transmitted to the tube elements and a microphonic howl may result.

This howl may also manifest itself when the chassis and speaker are being tested on a service bench thus making it very difficult to service the unit. The chassis or speaker should be cushioned as a preventive.

 (5) Measured from B. to A.V.C. Cathode.
 (6) Measured across 425 ohm bias resistor. B. to "Y" filament.

U. S. RADIO & TELEVISION CORP.

No. 1000X AND No. 1001X CHASSIS

Chassis No. 1000X and No. 1001X are almost identical in construction with chassis No. 1000 and No. 1001 except that they are designed for 25 cycle, 115 volt A.C. operation. The parts used in the 60 cycle chassis are also used in those chassis designed for 25 cycle operation with the exception of the power transformer and .06 Mfd. filter choke tuning condenser. The correct power transformer for the 25 cycle chassis as well as the correct filter choke tuning condenser are shown in the Parts Price List.

SUPPLEMENTARY NOTES FOR No. 1000 CHASSIS

The No. 1000 and No. 1001 Chassis are identically alike as regards the schematic circuit and the electrical constants. Referring to the schematic wiring diagram it will be noted the visual tuning meter is not drawn in solid lines but instead dotted lines are used. The significance of the dotted lines is to illustrate that the tuning meter is a component part of chassis No. 1001 whereas in chassis No. 1000 the meter is omitted the electrical circuit being completed by the joining of the two leads ordinarily connected to the meter leads on the 1001 chassis.

The electrical constants of the dual speakers used with each chassis are alike, however, the 1001 chassis has one 8 inch and one 10 inch

The description and testing as covered in the service notes for the 60 cycle chassis also applies to the 25 cycle chassis.

The 25 cycle chassis can be operated satisfactorily from a 60 cycle power supply. However, there may be excessive hum in which case it will be necessary to change the No. 1375 .45 Mfd. choke condenser to a No. 2854 .06 Mfd. condenser. The reverse is not true, that is, the 60 cycle chassis cannot be operated satisfactorily from a 25 cycle power supply.

electrodynamic speaker whereas the No. 1000 chassis utilizes two 8 inch speakers. The speakers for their respective chassis carry entirely different part numbers and these dissimilarities including other changes in a few of the parts for each chassis are enumerated in the parts list to follow.

It will be noted a number of the speaker parts for the No. 1001 chassis are interchangeable with the component parts of the speakers for the No. 1000 chassis and therefore it has not been thought necessary to make a repetition of these parts numbers in the accompanying list of the changes in parts for the No. 1000 chassis.

(1) (3) Computed value. Reading with voltmeter will be lower.
(2) This voltage read across 55 ohm section of shunt resistor.
(4) This voltage read across 935 ohm section of speaker field and 55 ohm section of shunt resistor.

Tuning Condenser Alignment

The tuning condensers are aligned at the factory with oscillators and output meters and the receiver will not normally lose its alignment unless mishandled or tampered with. When the condenser is out of alignment one or more of the sections are not in resonance and the receiver may receive a weak, broadcast band, or tune in a signal at two or more points of the dial.

The chassis should be grounded but the antenna is not connected. In case a strong enough signal is being received from the oscillator, connect a wire six foot length of wire to the antenna and run it over towards the oscillator. Next set the oscillator for a signal of 1,400 K.C. and carefully tune to resonance by turning the tuning condenser rotor slowly back and forth until maximum output is obtained. Now adjust the trimmer condensers to resonance. Adjust the volume control until the pointer of the output meter is at about half scale. The oscillator signal should not be too great in intensity as distortion will be introduced. The trimmer condensers are adjusted by raising or lowering the center screw. Turn the screws down until the volume starts to drop. Then adjust the trimmers to resonance, by raising or lowering the screws until maximum deflection is obtained. Adjustment may be made by turning a metal screw driver as the rotor is at its maximum potential.

Important point to remember in adjusting trimmer condenser is that the screws should be turned completely down. If they are turned in too tightly the capacity of the trimmer

condenser which is added to the capacity of the tuning condenser will be so high that the receiver cannot be tuned to a high frequency signal.

After the trimmer condensers have been adjusted at 1,400 K.C., they should not be changed in any way when aligning the tuning condensers at different frequencies as explained below.

Next set the oscillator for a signal of 1,000 K.C. Then turn the tuning condenser rotor carefully until maximum deflection is obtained on output meter. The second slotted section of the rotor will be approximately half way in mesh with the stator as shown in Fig. 3. Bend this section of the two end rotor plates of the first section of the tuning condenser in or out until maximum reading is obtained on the output meter. Follow the same procedure with section two of the tuning condenser. The corresponding slotted section on both ends of any rotor section should be bent in or out about the same amount for each adjustment.

After each material adjustment of a slotted rotor plate section, the tuning or setting of rotor for resonance should be checked. In other words, after every bending turn the tuning knob back and forth until maximum deflection of output meter is obtained before proceeding to make the next adjustment.

Next tune in a signal at 750 K.C. Follow the same procedure. Lastly, tune in a signal at 600 K.C. and again follow the same procedure. The condenser will then be properly aligned.

CENTER ROW OF LUGS USED AS WIRING TERMINALS ONLY

Power Transformer Terminals

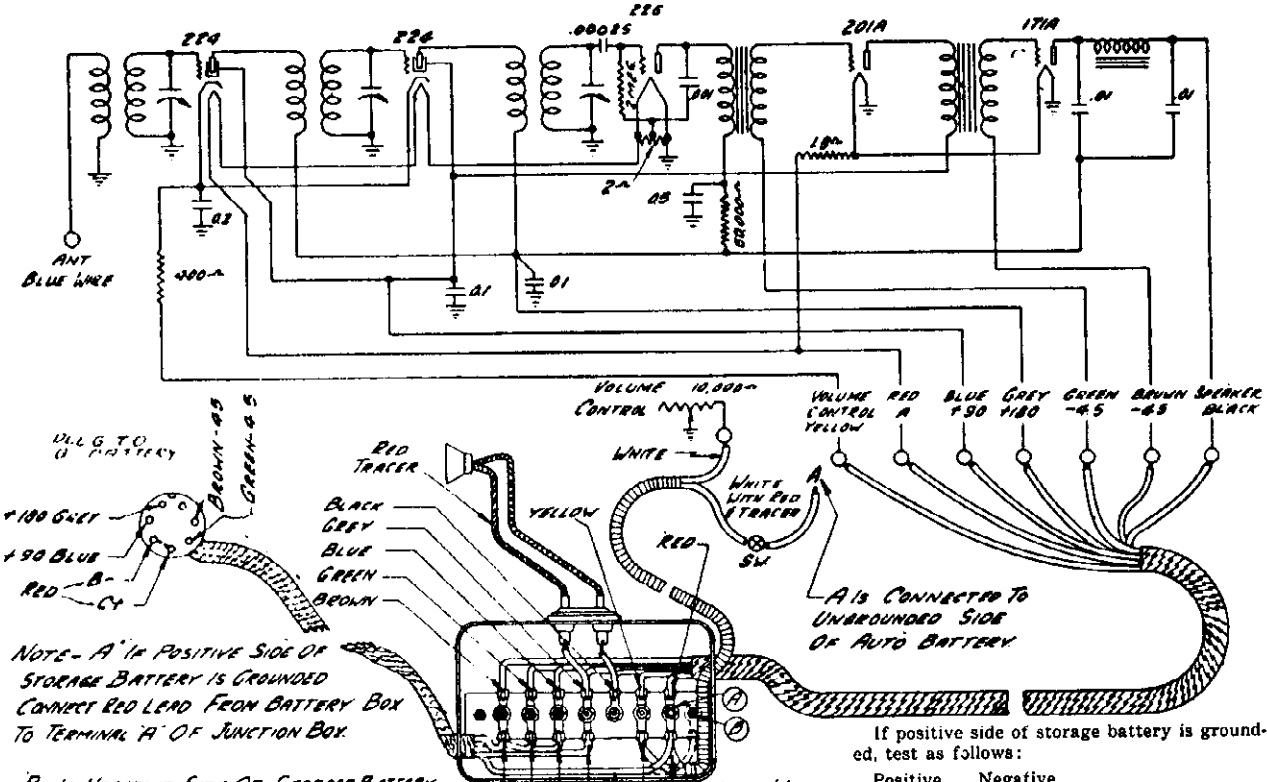

Electrodynamic Speaker

An especially designed electrodynamic speaker is supplied with the No. 20 chassis. The field of this speaker is energized by the power system of the chassis and is a part of the power system. For that reason no other speaker should be used with the No. 20 chassis than the one supplied with it.

Care should be taken in servicing the No. 20 receiver not to reverse the leads to one of the field sections as the fields will then "buck" and low signal strength will result. The field winding also acts as a filter choke.

MODEL 30 Auto Radio

ALL G TO BATTERY
 +100 GREY
 +90 BLUE
 RED - B
 RED - C

NOTE - A IF POSITIVE SIDE OF STORAGE BATTERY IS GROUNDED CONNECT RED LEAD FROM BATTERY BOX TO TERMINAL "A" OF JUNCTION BOX.
R IF NEGATIVE SIDE OF STORAGE BATTERY IS GROUNDED CONNECT RED LEAD FROM BATTERY BOX TO (GND) JUNCTION BOX MOUNTING SCREW AT "B"

If negative side of battery is grounded, test as follows:

Positive Lead on Terminal	Negative Lead on Terminal	Reading
Ground	1	45 Volt C
Ground	2	4.5 Volt C
3	Ground	90 Volt B
4	Ground	180 Volt B
7	Ground	6 Volt A

If any reading is below the lower limits as shown on the following list, a new battery box unit will be required.

Regular Rating	Lower Limit
180 Volt B	140 Volt
90 Volt B	70 Volt
45 Volt C	35 Volt
4.5 Volt C	3.5 Volt

If positive side of storage battery is grounded, test as follows:

Positive Lead on Terminal	Negative Lead on Terminal	Reading
7	1	45 Volt C
7	2	4.5 Volt C
3	7	90 Volt B
4	7	180 Volt B
Ground	7	6 Volt A

MODEL 99 Series Schematic

No. 99 Series

Power Transformer Terminals

There are certain features to be noted in this receiver. The mixer is of the autodyne type, wherein it functions as a mixer (1st detector) and also as an oscillator. Also that the grid lead from the mixer tube joins the grid coil at a tap upon this winding. This tap is so apportioned that the circuit acts to suppress the transmission of image frequency signals, in this case 524 KC higher than the frequency setting of the tuned circuit. The IF transformer is also of special structure combining the frequency setting and also the oscillator system. The structure of this transformer-oscillator is illustrated upon the next page.

MODEL 99 Series
Alignment
Voltage - Socket

U. S. RADIO & TELEVISION CORP.

CONDENSER ALIGNMENT

No. 99 CHASSIS

Aligning Intermediate Condensers—A non-metallic screw driver is necessary for aligning the intermediate condensers. A signal of 262 K.C. is required. Remove the grid cap from the grid connection of the 224 1st detector tube and connect the lead from the signal generator to the grid of the 224 1st detector. The tube shield should be left on. One way to make this connection is to bring the antenna lead from the signal generator through the slot in the end shield for the grid wire. A grid cap on the end of the antenna lead of the signal generator will facilitate making this connection. This lead, of course, should be insulated.

The oscillator coil must be shorted out by grounding the lead from the tap on the secondary. This is the white lead which comes through the porcelain base of the oscillator and I.F. assembly. This lead terminates at a lug on a vertically mounted bakelite terminal strip. Connect the jumper from this lug to the ground. Connect the ground lead from the signal generator to the ground post of the chassis.

The intermediate condenser adjusting screws are reached from the bottom of the chassis. There are two on the porcelain base of the oscillator and 1st I.F. transformer assembly, Part No. 3382 and one on the porcelain base of the 2nd I.F. transformer assembly, Part No. 3388. The volume control should be at maximum setting. Then adjust the three intermediate condenser screws until maximum output is obtained on the output meter. After all three have been adjusted the first time, go over them again and check the setting for maximum output.

Aligning R.F. and Oscillator Condensers—For adjusting the R.F. and oscillator condensers the signal input from the antenna generator should be made to the antenna post. Adjust the signal generator for a signal of exactly 1400 K.C. Then turn the tuning condenser rotor until the pointer is at exactly 1400 on the dial scale. Then adjust the three trimmers on the tuning condenser for maximum output adjusting the oscillator trimmer first (trimmer nearest back of chassis). Turn the screws up or down until greatest deflection on output indicating meter is obtained.

Then set the tuning generator for a signal of 600 K.C. and turn the tuning condenser rotor until the output is at maximum. The next step is to adjust the oscillator 600 K.C. trimmer condenser. The adjusting screw for this condenser is in back of the tuning condenser and is reached from the top of the chassis. To correctly adjust this oscillator 600 K.C. trimmer it will be necessary to turn the screw to several different positions using a nonmetallic screw

driver. At every position of this adjusting screw turn the tuning condenser rotor until maximum output is obtained. For each position of the adjusting screw there will be a maximum output and the correct position of the adjusting screw is the setting at which the deflection on output indicating meter is the greatest.

Next set the signal generator again for a 1400 K.C. signal and check the adjustment of the tuning condenser trimmers at this frequency for maximum output. Then set the signal generator for a signal of 1000 K.C. and turn the tuning condenser rotor until the output indicating meter shows maximum deflection. Then bend the slotted rotor plate sections of each tuning condenser bank which are last in mesh, in or out until maximum output is obtained. Tune in a signal at 750 K.C. and then at 600 K.C. and follow the same procedure bending the rotor plate sections last in mesh until maximum output is obtained. Do not change the setting of the oscillator 600 K.C. trimmer in any way after it has once been set as indicated above.

FLUTTERING OR MOTORBOATING

Fluttering or motorboating may be due to an open 8 Mfd. electrolytic filter condenser or to low capacity in this condenser. It may also be due to an open or low capacity .06 Mfd. screen by-pass condenser. If the 4 and 8 Mfd. electrolytic condenser units are reversed in position fluttering may result. The correct position of these two units is shown in Fig. 1.

A 224 1st detector with characteristics varying considerably from the standard may cause fluttering. Try out some new 224 tubes in this socket. A defective oscillator and 1st I.F. transformer assembly may also be responsible for this type of disturbance. If, after the tubes have been changed and the other possibilities suggested in this article have been investigated, fluttering persists, it may be advisable to secure a new oscillator and 1st I.F. transformer assembly and try it out in the receiver. Motorboating may be due to a poor grid connection to the 235 I.F. tube and to the 224 2nd detector.

ELECTROLYTIC FILTER CONDENSERS

There are two dry electrolytic condenser units in the No. 99 chassis. One of these units is an 8 Mfd. 450 volt condenser, Part No. 2803. The other unit is a 4 Mfd., 450 volt condenser, Part No. 3366.

In replacing the electrolytic condenser units great care should be taken to wire them in with the correct polarity. Tag the leads when they are taken off the old condensers. The positive terminal of the condenser is identified by a + symbol on the box. The positive lead in the chassis can be determined by referring to the schematic circuit diagram.

Top View of No. 99 Chassis showing Tube Sequence and Speaker Connectors.

No. 99X CHASSIS—25 CYCLE, 115 VOLT

Chassis No. 99X is almost identical in construction with chassis No. 99, except that it is designed for 25 cycle, 115 volt operation. All parts as used in the No. 99 chassis are used in the No. 99X with the exception of the power transformer. The correct power transformer for the No. 99X chassis is shown in the parts price list.

The description and testing as covered in the No. 99 Service Notes also applies to the No. 99X chassis

ZENITH RADIO CORP.

- * MODEL 91 (2014) SERIAL NUMBERS AFTER 373,334
* MODEL 92 (2014) SERIAL NUMBERS AFTER 301,394 (4B)

In all receivers, bearing serial numbers 373,334 on model 91 and 301,394 on model 92, or higher, the manual control has been removed from the A.V.C. cathode and placed in the grid circuit of the first A.F. stage. A tapped resistor takes the place of the original control. By use of this new system, the automatic volume control operates independently and at full efficiency, manual volume being controlled by varying the audio output.

Since the A.V.C. or R.F. circuit remains constant, the tuning meter will show maximum swing on the station at any manual control setting. Originally the meter action decreased as the volume was lowered.

The parts list shown previously, except for the substitutions given below, should be used when ordering replacement components.

PARTS CHANGE.

- 1 Audio volume control, part # 63-212 List \$ 1.65
1 Center tapped resistor, part # 63-210 List \$ 0.50
Deduct the 63-171 volume control.

-
- * MODEL 91 (2014) SERIAL NUMBERS AFTER 375,532
* MODEL 92 (2014) SERIAL NUMBERS AFTER 302,007 (4C)

All ten-tube Zenith Superheterodynes after the above serial numbers will incorporate a variable Sensitivity Control in place of the original Local-Distance switch. The diagram (*) indicates its position as being connected into the I.F. cathode. In addition to the control unit the first detector coil has been replaced by one having slightly different construction to provide equal sensitivity over the entire tuning range. It is not advisable to make this change in receivers subsequent to the above numbers, for the reason that each complete set of chassis coils must be inductively matched, otherwise the efficiency of the receiver will be seriously affected.

The following alteration makes the parts list directly applicable to the improved models:

ZENITH RADIO CORP.

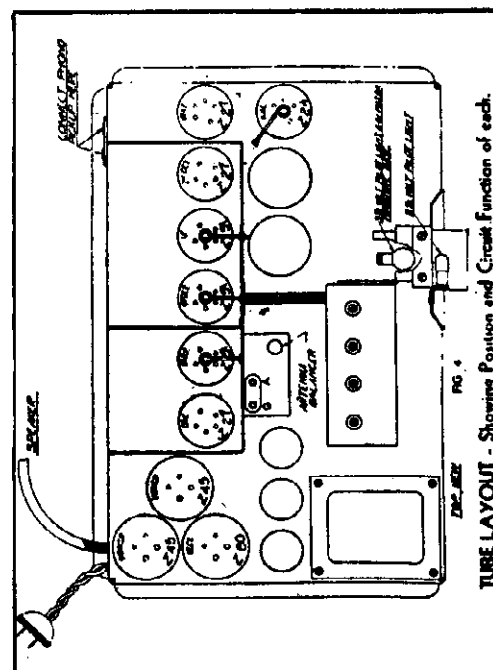

MODEL 91,92
Balancing Notes

Balancing Chassis

Every Zenith Superheterodyne Receiver is carefully balanced on laboratory equipment before leaving the factory and should not require further attention in this respect. However, in the event that some part of the R. F. circuit has been changed, or the adjustments shifted by mishandling, the chassis may be rebalanced as follows:

If an oscillator is available more accurate results will be obtained. It should be accurately calibrated from 1500 to 550 kilocycles and should also have provision for generating a 175 kilocycle signal. In cases where an oscillator is not available a fairly good result may be had by listening to stations which operate as nearly as possible to the extreme ends of the dial. Although an output meter will give most accurate results, satisfactory adjustments can be made simply by listening to the speaker.

The chassis should be removed from the cabinet so that all adjustments are easily accessible. Next place the test oscillator in operation and connect it direct to the antenna and ground posts of the receiver. It should then be set to 1500 kilocycles and the receiver tuned to the same reading on the dial. If the oscillator is not accurate the stations will not be received on their proper calibration. If a station is used for this purpose, the dial pointer should first be set to the exact frequency of the station being received. Beginning with the variable condenser tuning section at the extreme left, which tunes the oscillator circuit, the trimmer should be regulated for maximum response, in either the loud speaker or output meter. It will be noticed that the second section does not employ a vernier adjustment. This stage is resonated by adjusting the antenna compensator knob as explained in the instruction card. The third, or 1st R. F. trimmer, is adjusted in the same manner as the oscillator. If at any time the volume reaches a very high level, so that it is not possible to determine slight changes, it should be reduced by means of the volume control knob so as to be barely audible. The fourth, or 1st detector section, is next in order and its trimmer should also be adjusted for resonance.

After the vernier adjustments have been completed the test oscillator should be set at 550 kilocycles and the dial of the receiver turned until the oscillator signal is tuned in. Now the oscillator padding condenser (see fig. 3) should be very carefully adjusted with a screw driver for maximum output of the receiver, while rocking the tuning condenser back and forth over the signal. This padding adjustment brings the oscillating circuit of the receiver in resonance with the remaining tuned circuits and, thereby, enables it to tract accurately over the entire scale. The receiver will now operate at full efficiency and all stations will be received at their proper calibration. If this is not found to be entirely so, the entire balancing operation should be repeated.

The intermediate transformers used in the ten tube Superheterodyne have been accurately peaked at 175 kilocycles on a temperature controlled crystal oscillator before leaving the factory. It is not recommended that their adjustments be tampered with unless an oscillator is available which is very accurately calibrated at 175 kilocycles, or unless the serviceman is absolutely certain the trouble lies in their adjustment. However, if it is necessary to check the adjustments, the 175 K. C. test oscillator may be connected to the grid terminal of the 1st detector through a .00025 fixed condenser. The ground lead of the test oscillator is connected to the ground post of the receiver. The oscillator tube must be removed from the chassis while this operation is being performed. Four adjusting screws are provided under the chassis directly beneath the intermediate transformers, which tune the plate circuit of the 1st detector, grid and plate circuits of the I. F. stage, and grid circuit of the second detector. (See wiring diagram.) Beginning with the 2nd detector grid vernier, each adjusting screw should, in turn, be set for maximum signal output from the speaker or output meter. For best results the verniers should be gone over twice in the same rotation always keeping the output from the test oscillator at the weakest possible strength in order to determine slight variations in volume.

**CIRCUIT DIAGRAM
POWER UNIT**
MODELS
10, 11, 12 and 102, 112, 122

A new development in the form of capacity coupling is used between the R. F. stages. Close examination will reveal the fact that it comprises a single band of bus-bar wire. This band is connected from the plate terminal of the preceding R. F. stage and coupled to the grid coil of the following R. F. stage. The position of this band is permanently adjusted at the factory and should never be altered or tampered with unless the available line voltage is extremely low.

The distance from the coupling band to the grid or top end of the R. F. coil entirely governs the stage coupling and efficiency of the set. If this band is too close to the grid end, excessive coupling will result, causing a decided lack of selectivity. If the band is placed too low, the result will be a lack of sensitivity. Midway between the coil winding is the exact and most efficient operating position. If it is found necessary to reset this band, insulating cement or other fastening substance should be applied to hold it in position, since loose vibration would cause frequency flutter.

The R. F. plate chokes are concealed beneath the R. F. coil base, between the base and sub-panel. These chokes have an inductance of 6.75 M. H. and can be distinguished from the detector plate choke by the fact that they have 150 less turns. If an occasion arises which necessitates removing an R. F. choke, the serviceman should make certain that the 1/8" spacing is maintained between the choke and the R. F. coil base. To neglect this important adjustment may cause erratic operation of the receiver.

Occasionally, and especially if the receiver has remained idle for a long length of time, it may have a tendency to oscillate. This is always due to poor contact between the wipers and rotor bearings of the variable condenser gang. It may be overcome by cleaning both parts with fine sandpaper or by revolving the dial several times to remove oxidization at that point.

BALANCING

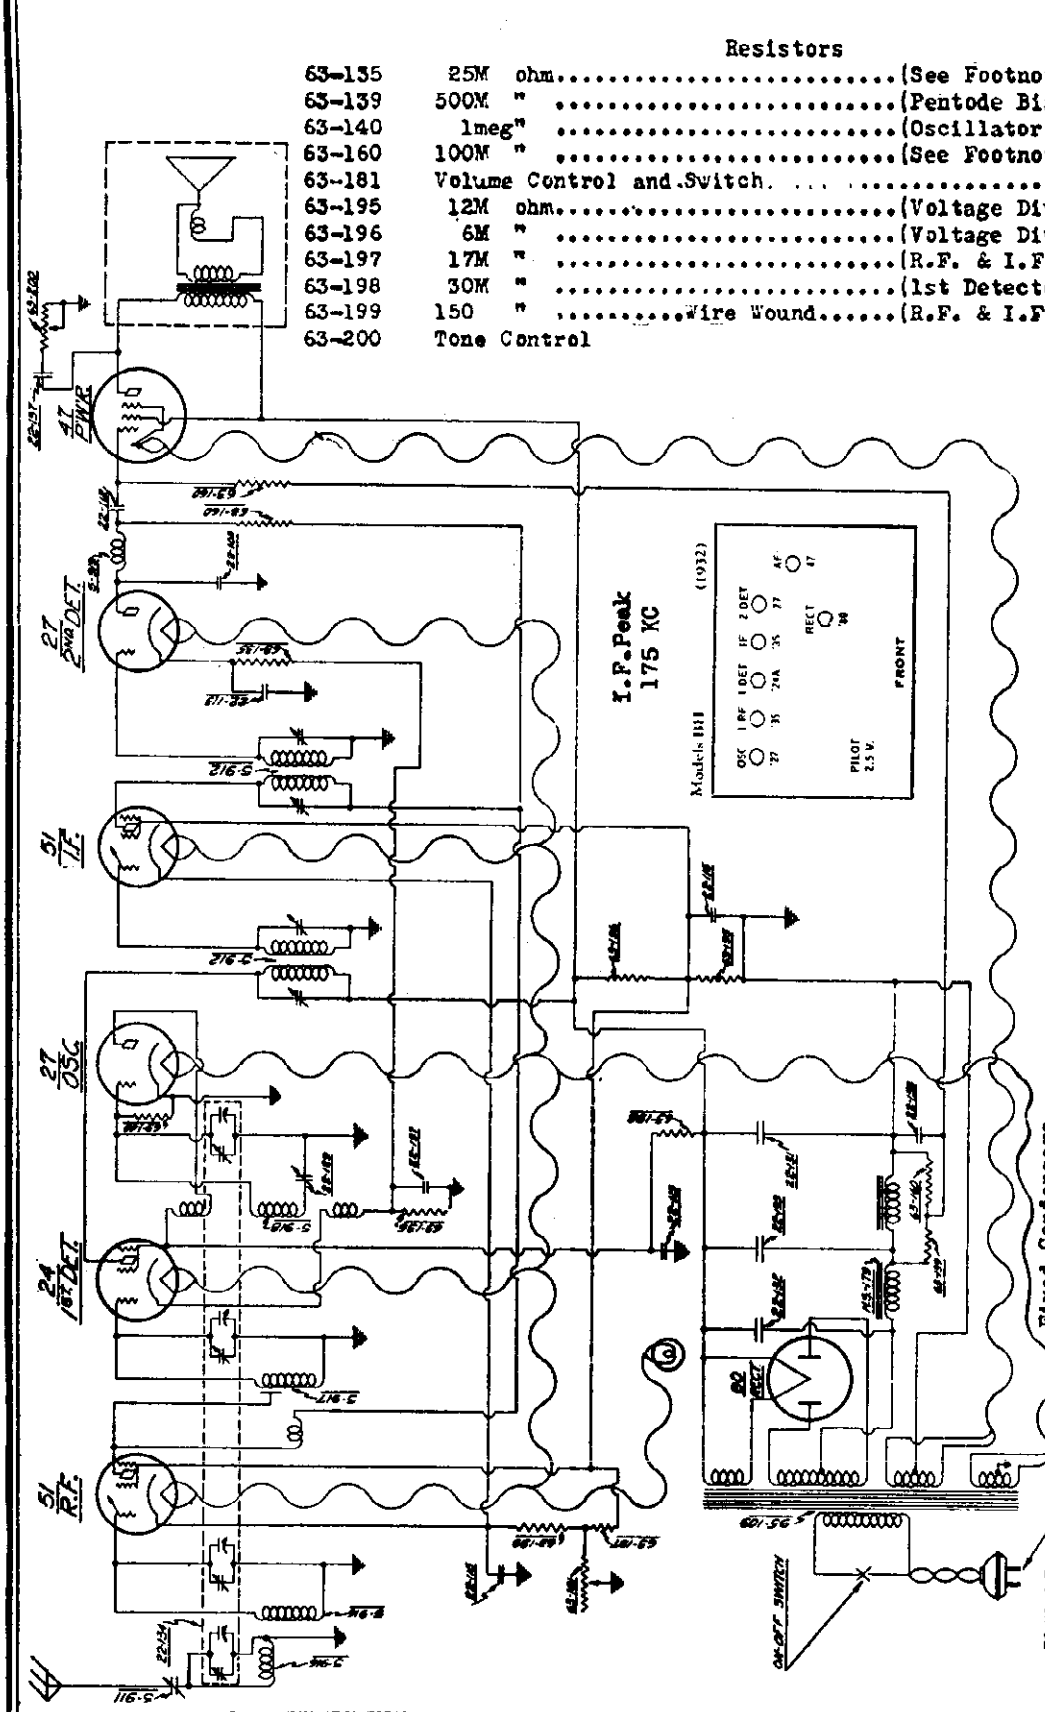

When resonating the variable condenser system for most efficient receiver performance, it will be noticed that an entirely new and fool-proof system of locking the verniers has been employed. The large locking nut may be loosened with a No. 6 Spintite wrench and the vernier screw turned with a small pointed screw driver.

Proper method of balancing is accomplished by setting the antenna input control first on the No. 1 position. A station of low wavelength should be tuned to resonance on the dial. Adjust each trimmer condenser to exact resonance or so that it is set to peak volume. After this has been done, the input control should be set to the No. 2 position and the antenna section trimmer readjusted.

Upon completion, make certain that the wavelength of the station chosen corresponds to the proper wavelength reading on the drum dial.

 Schematic Notes

ZENITH RADIO CORP.

It should be noted that the line fuse provided in the rear of the chassis has two positions. The fuse should normally be used in the "Regulator Tube In" position. If the regulator tube becomes defective and a replacement is not immediately available, the fuse may be placed in the "Regulator Tube Out" clips. Do not leave the voltage regulator tube out permanently since line fluctuations or high voltage may cause damage to the tubes or power transformer.

It should be noted that the phonograph pickup switch and jacks are connected in the grid return circuit of the second detector, consequently a howl will be heard if the phono switch is thrown to the phono position without a phono pickup having been attached. Be sure this action is taken into consideration when servicing the receiver or if there is a complaint of very weak reception accompanied by a very peculiar howl.

Z-80	Rect.	5.	*350	-	-	-	*36

Line 115 Volts

All Controls Maximum

All readings, with exception of heaters, taken from socket connections to ground. Use 1,000 ohm per volt D. C. meter.)

BALANCE I.F. frequency at 175 K.C. Condenser gang at 1500 K.C. and oscillator padder at 600 K.C.
