FM STEREO / FM-AM RECEIVER

SPECIFICATIONS

Fm Tuner Section

Tuning range:	87.5 MHz to 108 MHz
Usable sensitivity:	2.6 μV (IHF) 2.2 μV (S/N = 30 dB)
Signal-to-noise ratio:	70 dB
Capture ratio:	1.5 dB
Frequency response:	20 Hz to 15 kHz ±1 dB
Stereo separation:	38 dB at 400 Hz

A-m Tuner Section

Tuning range:	530 kHz to 1,605 kHz
Sensitivity:	48 dB/m, built-in bar antenna (S/N = 20 dB) 20 μV, external antenna
Signal-to-noise ratio:	50 dB

Audio Amplifier Section

Dynamic output power: (IHF constant power supply method)	145 watts (4 ohms), both channels operating 100 watts (8 ohms), both channels operating
Continuous output power: (rated output)	50 watts (4 ohms) per channel, both channels operating 40 watts (8 ohms) per channel, both channels operating 60 watts (4 ohms), each channel 43 watts (8 ohms), each channel

Harmonic distortion: less than 0.2% at 1 kHz at rated output
less than 0.1% at 1 watt output

Frequency response: PHONO: RIAA curve ±0.5 dB
TAPE: 10 Hz to 60 kHz
REC/PB: 10 Hz to 60 kHz

General

Power consumption:	160 watts (USA Model) 200 watts (UK, AEP and EP Model) 160 VA (Canada Model)
Power requirement:	117 volts ac (USA and Canada Model) 100, 117, 220, 240 volts ac (EP, UK and AEP Model)
Dimensions:	440(w) x 148(h) x 345(d) mm 17 5/16(w) x 5 13/16(h) x 13 9/16(d) inches
Net weight:	12 kg (26 lb 7 oz)

	<u>General</u>	<u>Stage/Control</u>	<u>Function</u>
Power consumption:	160 watts (USA Model) 200 watts (EP, UK and AEP Model) 160 VA (Canada Model)		L104.
Power requirement:	117 volts ac (USA and Canada Model) 100, 117, 220, 240 volts ac (EP, UK and AEP Model)	AFC circuit D101, D102 C120	An automatic frequency control circuit is incorporated in the oscillator circuit to eliminate frequency drift and precise tuning difficulty. The principle of afc operation is as follows: When the tuner is correctly tuned, the intermediate frequency is 10.7 MHz and no dc correction voltage is produced by the ratio detector as shown in the "S" curve response of Fig. 1-1. Thus the voltage applied to diode D101 is determined solely by the positive fixed reverse bias voltage supplied by zener diode D102. Now assume that the local oscillator frequency changes by $\pm\Delta f$. This means that the new intermediate frequency is 10.7 MHz $\pm\Delta f$. See Fig. 1-1. As the result a positive dc component is fed back to the anode of D101, decreasing the reverse voltage to it, and making D101's barrier capacitance increase. This decreases the local oscillator's frequency, since the series circuit composed of C120 and D101 is connected in parallel to the tank circuit of the local oscillator. Conversely, if the local oscillator frequency decreases a negative dc voltage is fed back to D101 increasing the local oscillator frequency.
Dimensions:	440(w) x 148(h) x 345(d) mm $17\frac{5}{16}$ (w) x $5\frac{13}{16}$ (h) x $13\frac{9}{16}$ (d) inches.		
Net weight:	12 kg (26 lb 7 oz)		
Shipping weight:	16 kg (35 lb 5 oz)		

1.2. DETAILED CIRCUIT ANALYSIS

The following describes the function or operation of all stages and controls. The text sequence follows signal paths. Stages are listed by transistor reference designation at the left margin; major components are also listed in a similar manner. Refer to the block diagram on page 12 to 14 and the schematic diagram on page 51 to 56.

<u>Stage/Control</u>	<u>Function</u>
Fm Front End	
Balun B1	This transformer matches 300-ohm twin lead to the fm front-end's input stage, thereby coupling the receiver signal to the front-end.
Passive rf circuit	A triple-tuned circuit is employed between the antenna and mixer transistor. This passive coupling circuit contains no active amplifiers, so it is perfectly linear and cannot produce distortion and overload components. Thus, the factors that contribute to spurious responses are eliminated ahead of the mixer.
Local oscillator L104, Q102	Supplies heterodyning voltage to the mixer via L104. The circuit is a modified Hartley type with feedback applied to the emitter of Q102 from the tap on
C120	
Mixer Q101	RF signals and local oscillator voltage are heterodyned in the gate-source junction of mixer Q101 to produce 10.7 MHz i-f output signal.
IFT101	Transformer IFT101 and capacitor C106 and C107 form a 10.7 MHz "high-C" tuned circuit. This type of circuit has the advantage of reducing the higher order harmonics of 10.7 MHz which cause cross-modulation or spurious interference.

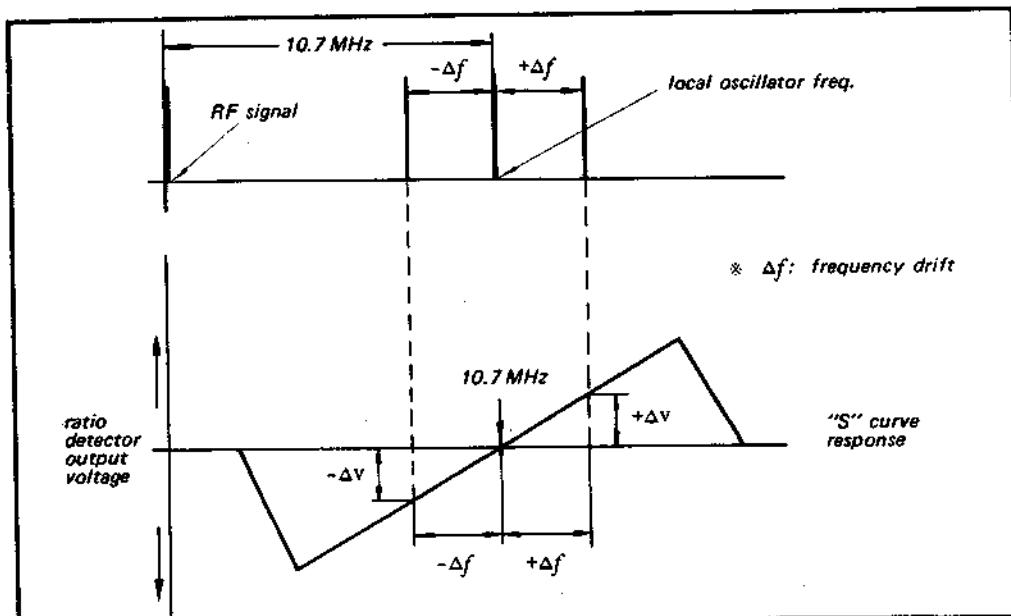

Fig. 1-1. Local oscillator frequency drift and afc voltage relationship

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
I-f preamplifier Q103	The i-f signal coupled to the base of i-f preamplifier Q103 by the secondary winding of IFT101 is amplified to achieve a favorable signal-to-noise ratio before application to the filters in the i-f strip.	Diode limiters D201 to D206 D209, D210	filters. Q206 provides power to drive the ratio detector.
I-f Amplifier			Limiting is accomplished by diode pairs, connected in parallel and poled in opposite directions. The diodes conduct when the signal across them exceeds the barrier potential of about 0.6 volts in the forward direction. Thus the signal is limited in both directions to 1.2 volts peak-to-peak. The diodes provide symmetrical limiting.
I-f amplifiers Q201 to Q205 CF201 to CF206	These i-f stages are basically RC coupled amplifiers (except Q205) that provide essentially flat response. The selectivity of this section is determined by three pairs of filters CF201, CF202, CF203, CF204, CF205 and CF206 in the interstage coupling path. Each of these filters is a two-section ceramic filter that operates in the "trapped-energy" mode. The filters provide extremely-sharp skirt selectivity and flat response inside the passband. Thus, these filters largely determine overall tuner selectivity.	Ratio detector D207, D208	T201 and diodes D207 and D208 form a balanced ratio detector that transforms the frequency-modulated signal into an audio signal. Output appears across C216.
I-f output Q206	Signal at the base of Q206 has had all amplitude variations removed by the preceding limiters, and only selected signals have been passed by ceramic	Muting circuit Q207, Q208, Q209, Q210 D211 to D213	The i-f signal is extracted from limiter diodes D203 and D204 to drive the muting circuit. The extracted i-f signal is amplified by Q208 (FET) enough to drive voltage doubler D212 and D211 through tuned transformer T202. D213 provides positive fixed bias for Q209 through D212 and D211. T202 determines the bandwidth necessary to con-

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
Stereo-mono automatic switching circuit Q210, D409	<p>trol the muting circuit without generating interstation or detuning noise. The output of the voltage doubler is a positive dc voltage proportional to the carrier levels of weak rf signals. Q209 and Q210 form a switching circuit which is driven by the voltage doubler. Q209 is normally cut off, thus forcing Q210 into conduction. The collector of Q210 is connected to the gate of FET Q207 through MUTING switch S7. FET Q207 acts as an electronic switch which is inserted between the ratio detector and MPX decoder, and is controlled by the gate voltage applied. With the MUTING switch ON, fm signals of average strength keep Q209 saturated, thus cutting off Q210. This causes Q207 to conduct and maintain normal operation.</p> <p>Weak stations and interstation noise can not produce sufficient dc voltage at the base of Q209 to keep it conducting. As a result, Q209 cuts off. This saturates Q210 and cuts off Q207, accordingly, the audio output is muted. With the MUTING switch OFF, Q207 is kept conducting regardless of the strength of the fm signal by a positive bias voltage on its gate. RV201 adjusts the muting level.</p>	SCA trap L203, C220	The composite signal containing monaural information from 0 to 15 kHz, the 19 kHz pilot carrier, and the fm stereo signal at 38 kHz is fed to Q207 through trap L203-C220. This trap removes the unwanted SCA signal to the base of Q401 (the 19 kHz amplifier) through Q207.
	<p>The collector of Q210 is also connected to the output terminal of the MPX decoder's frequency doubler through diode D409. This prevents noisy stereo reception by automatically switching the MPX decoder's operation into the monaural mode. This is needed because in fm stereo broadcasting, the S/N ratio of a demodulated stereo signal degrades much more rapidly than that of a mono signal when</p>	MPX Decoder 19 kHz amplifier Q401	This stage serves two functions. It extracts the 19 kHz pilot signal by means of a tuned circuit at its drain, and provides a low-impedance source of composite stereo signal (without pilot carrier) at its source. By using an FET, harmonics of the 19 kHz and 38 kHz components are reduced to a low level thereby causing less carrier leak or beat interference.
		Frequency doubler D401, D402	Signals developed at the collector of Q401 are transformer coupled to a fullwave rectifier consisting of D401 and D402.
		TUNING meter M901	In fm mode, center-zero meter assures correct tuning by utilizing the ratio detector's characteristic.
		R263	As indicated in Fig. 1-1, no dc voltage is produced across R263 when the tuner is correctly tuned. Deflection on the meter indicates the amount of deviation from the carrier frequency received.
			Note that the meter will indicate zero-reading when the tuner is not receiving any off-the-air signal.

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
	The output of this rectifier is not filtered, resulting in two positive pulses for each input cycle. Thus, the 19 kHz pilot-carrier frequency is effectively doubled by D401 and D402. However, the waveform is not sinusoidal at the base of Q402.		R405, the stereo indicator lamp, R412, R414, and R413, so these diodes merely act as small resistances. Under this condition, the monaural signal is applied to both "L" and "R" audio amplifiers.
38 kHz amplifier Q402	The 38 kHz pulses produced by D401 and D402 are amplified by Q402. The tank circuit at the collector of Q402 is tuned to 38 kHz to restore these pulses to a sinusoidal waveform. This signal is transformer coupled to the bridge-type demodulator to supply sampling drive for the demodulator.	De-emphasis capacitors C413, C414, C422, C423	These capacitors provide the roll off at high audio frequencies necessary to compensate for pre-emphasis at the transmitter. S10 should be set to the proper time constant. Specified de-emphasis time constant is 75 micro-seconds in USA and CANADA, 50 micro-seconds in Europe.
STEREO lamp circuit Q403	The STEREO indicator lights when the FUNCTION switch is set to the FM-AUTO STEREO position and an fm stereo signal is received. The emitter of Q402 is connected to the base of Q403 (which is normally cut off). The circuit operates as follows: When a composite stereo signal is applied to the multiplex decoder, the 38 kHz pulses produced at the output of the frequency doubler yield a higher average current flow through Q402. This forces Q403 into conduction, lighting STEREO indicator lamp PL904.	Audio preamplifier Q404, Q405 Q406, Q407	Demodulated L and R signals are amplified by these stages to the level required at the input of the following low pass filter.
Multiplex demodulator D405, D406, D407, D408	The demodulator circuit employs four diodes in a balanced-bridge arrangement. This system has the advantage of cancelling residual rf components (38 kHz signal, some 19 kHz signal, and higher-order harmonics of these frequencies.) "L" and "R" components are developed at each side of the bridge as the result of demodulation, when the receiver is operated in the stereo mode. In the monaural mode, diodes D405 and D408 are forward biased by supply voltage through	Separation control RV401	The network that connects the emitters of Q404 and Q405 provides a form of negative feedback between left and right channels. Any residual "L" signal in the "R" channel (which is about 180° out of phase) is cancelled out by the "L" signal from the "L" channel. The same is true of residual "R" signal in the "L" channel. RV401 is therefore set for maximum separation.
		LPF401	Filters out the unwanted higher-order harmonics of 19 kHz and 38 kHz leakage to obtain clear audio.
		A-m Tuner	Note: As two kinds of a-m circuit exist due to production changes, we describe the each circuit operation corresponding to respective serial numbers.
		USA Model	Serial No. up to 810,400
		Canada Model	Serial No. up to 700,300

		Local oscillator Q305	This stage supplies injection voltage to the mixer via L303. In

STR-6055

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
Mixer Q301	<p>this oscillator circuit feedback is applied to the emitter of Q305 from low-impedance winding on oscillator coil L304.</p> <p>Incoming rf signals and local-oscillator voltage are heterodyned in the base-emitter junction of Q301 to produce the 455-kHz output.</p> <p>FET Q302 couples the output of the mixer to IFT-301. This stage functions as the gain control element of the AGC system as will be explained later. IFT301 is a transformer tuned to 455 kHz. It develops the i-f signal, and provides a path to ground through bypass capacitor C307 for the other heterodyne products. The low-impedance output winding of IFT301 provides link coupling to i-f amplifier Q303.</p>	Agc circuit	<p>the anode of D303 is filtered by C313, R336, and fed to the TUNING METER.</p> <p>The negative dc component at the anode of diode D302 is filtered by R325, C336, C335, R335, C322, R326, C323 and fed back to the gate of Q302 to control its gain. The time constants of the agc filter components remove audio variations from the agc voltage.</p> <p>USA Model..... Serial No. 810,401 and later Canada Model..... Serial No. 700,301 and later EP Model..... Serial No. 553,001 and later UK Model..... Serial No. 600,001 and later AEP Model..... Serial No. 900,001 and later</p>
If amplifier Q303	This stage is basically an RC-coupled amplifier. The selectivity of the stage is determined by a double ceramic filter (CF301) in the interstage-coupling path. This filter provides extremely sharp skirt selectivity inside the passband.	Antenna circuit	A-m signals are received by the antenna tank circuit formed by L904, C302, L902, CV901, CT301, C305 and C304. C302 is selected not for its effect upon tuning, but to reduce spurious radiation by the local oscillator.
CF301		Low-pass filter L301, C302	The low pass filter (L301 - C302) reduces the spurious radiation caused by local oscillator which may interfere another receiver or communication system through the external antenna.
If amplifier Q304	This circuit provides the power to drive diode detector D302.	Local oscillator Q305	This stage supplies the injection voltage necessary to receive a-m signal. In this modified Hartley oscillator circuit, feedback is applied to the emitter of Q305 from a low-impedance winding on oscillator coil T301.
Detector D302	The i-f signal from the secondary of IFT302 is rectified by diode D302. The i-f components of the output signal are filtered by C317, C318, and R320. The output appearing across R322, R323 is therefore clean audio.	Mixer Q301	Incoming rf signal is fed to the base of Q301, while the local-oscillator voltage is injected to the emitter circuit of Q301. These two signals are heterodyned in the base-emitter junction of Q301 to produce the 455-kHz output. This stage functions as the gain control element of the agc system due to Q302 in the emitter circuit, as will be explained later.
TUNING meter M901	<p>In a-m mode, deflection on this meter indicates the relative signal strength of the selected a-m station.</p> <p>The a-m i-f signal is extracted from secondary winding of IFT302 to drive TUNING METER M901. The extracted i-f signal is rectified by D303. The negative dc component at</p>	CFT301	CFT301 is a combination unit which contains a double-tuned circuit and one ceramic filter

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
I-f amplifier Q303	tuned to 455 kHz. It develops the i-f signal, and determines the selectivity inside the passband. It also provides link coupling to i-f amplifier Q303.		
I-f amplifier Q304	This stage is basically an RC-coupled amplifier and amplifies the i-f signal to the proper level required by the following stages. Q304 and IFT301 form a tuned amplifier circuit which provides power to drive diode detector D302.		
Detector D302	The i-f signal from the secondary side of IFT301 is rectified by diode D302. The i-f components of the output signal are filtered by C318, R320 and C319 and then cleaned audio signal is fed to the audio preamplifier through FUNCTION switch S1.		
TUNING Meter M901	The detector (D302) output is also fed to TUNING meter M901 as the dc component in the rectified a-m signal is roughly proportional to the input signal level (not exactly for strong signals due to agc action).		
AGC circuit	There are two feedback loops which provide proper agc operation. One is the minor loop applying AGC to the i-f amplifier Q304 base circuit. The other is the major feedback loop applying dc from the emitter circuit of Q304 to the emitter circuit of Q301 through Q302. The minor feedback loop consists of D301, R317, C326, R326, C325 and R314. The a-m i-f signal is extracted from the collector circuit of Q304 through C314 and rectified by diode D301. The output of the diode D301 is a positive dc voltage roughly proportional (not exactly due to agc action) to the carrier levels of input signal and fed to the base of Q304 through a filter circuit. Thus the out-		put of diode D301 controls the current flow in Q304 and its emitter voltage as well. Major feedback is produced by the emitter circuit of Q304, R315, C322, C321, R325 and Q302. The emitter voltage of Q304 is applied to the base of Q302 through the filter circuit, determining the positive bias on Q302. As the Q302 shunts the emitter resistor of mixer Q301, it controls the operation of Q301 as a forward agc element. When the strong signal is received, Q302 is forced into conduction, shorting Q301 emitter to ground through R305. As a result, current flow in the Q301 (mixer) increase, reducing its current gain and allowing stable operation in a strong field-strength area.
Preamplifier Section			
Equalizer amplifier Q501, Q502	These direct-coupled stages amplify the small signal provided by the phono cartridge to the level required at the input of the following tone-control amplifier.		
Bias circuit R503, R508	Dc bias voltage for Q501 is extracted from R508 in the emitter circuit of Q502 and fed back to the base of Q501 through R502 and R503. This dc negative feedback technique provides stable operation during temperature changes.		
Equalization circuit R509, R510, R511 R505 C505, C506	RIAA equalization is achieved by the negative-feedback loop containing R509, R510, R511, R505, C505 and C506. Be sure to use replacement components with the exact same values.		
Equalization circuit	R513 (R563) in the output circuit prevents interaction between left and right channel-equalization when the MODE switch is set to L+R.		

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
MODE switch S4	In the STEREO position of S4, left and right input signals are routed to their respective amplifiers. In the L+R position, the left and right signals are added and the sum is then fed to both amplifier channels. A rotary switch having two sections is used to obtain L+R signal even if the MONITOR switch is set to the TAPE position.	BASS control RV604 (RV654)	Similar to the treble control except for filter components and frequency characteristics, however in this circuit the negative feedback voltage is determined by the setting of RV604. This has a range of ± 10 dB at 100 Hz.
VOLUME control RV601 (RV651)	The equalized phono signals and signals applied to the other input terminals are fed to the VOLUME control through the MONITOR and MODE switches. The level of the signal applied to the following tone-control amplifier is determined by the setting of RV601.	HIGH FILTER S6	The high-cut off filter (R616 and C613) eliminates unwanted high-frequency components (5 kHz and higher) from the input signal when this switch is ON.
LOUDNESS switch SS	This switch and R601, R602, C601, C602 compensate for the characteristics of the human ear which vary according to the loudness of the sound being heard. When this switch is set to ON and the VOLUME control is set for 30 dB attenuation, the overall frequency response is increased 10 dB at 50 Hz and 4 dB at 10 kHz with reference to the level at 1 kHz.	Preamplifier Q701, Q702	Q701 and Q702 form a para-phase amplifier but signal output is extracted from the collector circuit of Q701. This circuit has a various advantages in direct coupling system. One is high stability despite temperature variations and another is high input impedance without reducing the amplifier's gain. The ac output appears across load resistor R705 (R755) in the collector circuit. An emitter decoupling circuit is formed by the emitter-base resistance of Q702, C702 and R708 in the base circuit of Q702.
Tone-control amplifier Q601, Q602 (Q651, Q652)	This direct-coupled two-stage amplifier has basically flat response, but it operates as a negative-feedback type tone-control circuit. The output generated at the collector circuit of Q602 is fed back to the emitter circuit of Q601 through the treble and bass tone-control network.		This circuit forms a frequency-selective ac bypass circuit to reduce the amplifier's gain at very low frequencies. Common emitter-resistor R706 keeps the dc current flow constant in the Q701 and Q702, thus increasing dc stability.
TREBLE control RV603 (RV653)	Increases or decreases the amount of negative feedback voltage determined by the setting of RV603. It has a range of ± 10 dB at 10 kHz.	Bias power supply D701, D751	These diodes are forward biased by positive and negative power supply voltage through RV701 and RV751. They provide a stabilized voltage to bias transistor Q701 that is used to make the output terminal balance at zero dc through RV701.
		Dc balance adj. RV701 (RV751)	

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
Thermal compensation and noise suppressor D711	As all the stages are directly coupled, dc stability is required. The negative temperature coefficient of D711 provides thermal compensation for the following driver stage. It also acts as a noise suppressor to reduce the popping noise due to unbalanced current flow in the following stages when the power switch is turned off.		about $\pm 40V$. Q709 supplies power to the load during the positive half cycle and Q710 operates during the negative half cycle. As all the stages are directly coupled and designed to obtain zero potential at the output terminal, the large coupling capacitor at the output (which may cause power loss or distortion at low frequencies) is eliminated.
Driver Q703	Though this stage is a conventional flat amplifier, it determines the output voltage swings because the following stages are basically in the emitter-follower configuration. The ac load resistor for this stage is R712.	Protection circuit	To protect overloaded power transistors from destruction, a new protection circuit is employed. If a short circuit at the output terminals occurs, the protection circuit holds the current in the power transistor low enough not to make it overheat and also limit the input drive signals.
Dc bias adj. (Idling current) Q704, RV702	Q704 is forced to conduct and operates as a small resistance providing the necessary forward bias on the two cascaded emitter-followers. RV702 controls the base bias of Q704, determining the impedance between the emitter and collector of Q704, and thereby controls the dc bias voltage for the following complementary circuit.		Fig. 1-2 shows a partial schematic diagram detailing the protection circuit. With reference to this diagram, the protection circuit operates as follows:
Thermal compensator for dc bias D702	The negative temperature coefficient of D702 provides thermal compensation for the complementary and power transistor circuits. D702 is attached to the power transistor's heat sink to detect temperature change in the power transistors.		Since the protection circuit is identical for positive going half cycles and negative going half cycles, only the positive going half cycle operation is described here. Q705 limits the positive-going half cycle of the drive voltage applied to the base of Q707 when power consumption at the Q709 collector exceeds the safety margin. Since power dissipation at the collector can be considered a function of collector voltage and current, the trigger signal for Q705 is taken from the collector and emitter. Base voltage is partly determined by the ratio of resistance of R719 and series resistance of R726 and RL (load). Base voltage is also determined by the current flow in the R733 and the collector voltage of Q709. Under normal operation, Q705 is cut off.
Complementary circuit Q707, Q708	These transistors operate as emitter-followers to provide the current swings demanded of the output stages and also provide the necessary phase inversion. Phase inversion is performed by using PNP and NPN type transistors.		
Power transistor Q709, Q710	The output transistors (Q709 and Q710) are connected directly to a power supply of		

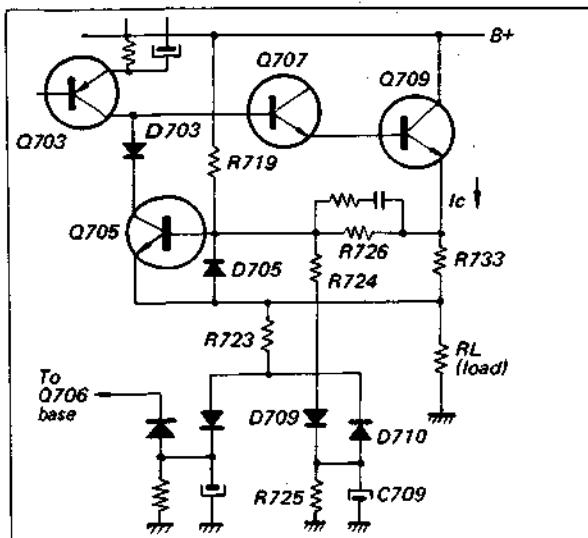

Stage/ControlFunction

Fig. 1-2. Simplified protection circuit

When excessive current flows in the power transistor or power dissipation at the collector of power transistor exceeds the specified value, Q705 turns on and limits the input drive voltage to the power transistor. Limiting operation is also actuated by the condition of the load. The base voltage of Q705 is determined by the resistances R733, R726, R724, R725, and RL (load). D709 is employed to stop reverse voltage from applied being during the negative going-half cycle. Q705 turns limiting the input drive voltage to the power transistor when the load resistance decreases to some extent. Under reactive load conditions in class B amplifiers maximum current will flow when the voltage across the power transistor is maximum and this is the worst case for secondary breakdown. See Fig. 1-3. As all speakers have reactive properties, a protection circuit which covers the reactive region is required.

Fig. 1-3 shows the operating load lines for one half of a class B output stage under con-

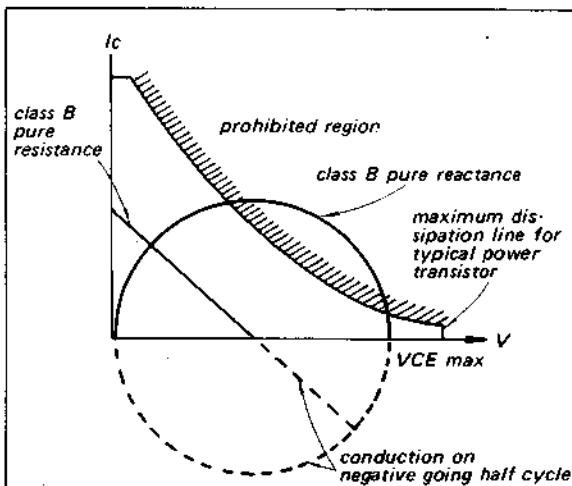

Stage/ControlFunction

Fig. 1-3. Resistive and reactive load lines for class B output stage showing breakdown risk in purely resistive load

ditions of equal load impedance; in one case the load is purely resistive and in the other case purely reactive. It is apparent that the reactive load case could result in transistor failure. D710, C709 and R723 form a circuit charging the base voltage according to the reactive voltage induced in the load to obtain proper protection operation. C709 and R725 form a discharging circuit to detect reactive dc voltage. D705 protects Q705 from breakdown between base and emitter due to detected reactive voltage across C709. D703 protects Q705 from the breakdown between collector and emitter during the negative-going half cycle.

Power supply
rectifier
D801

A full-wave bridge rectifier provides a positive and a negative dc power supply for the power amplifier.

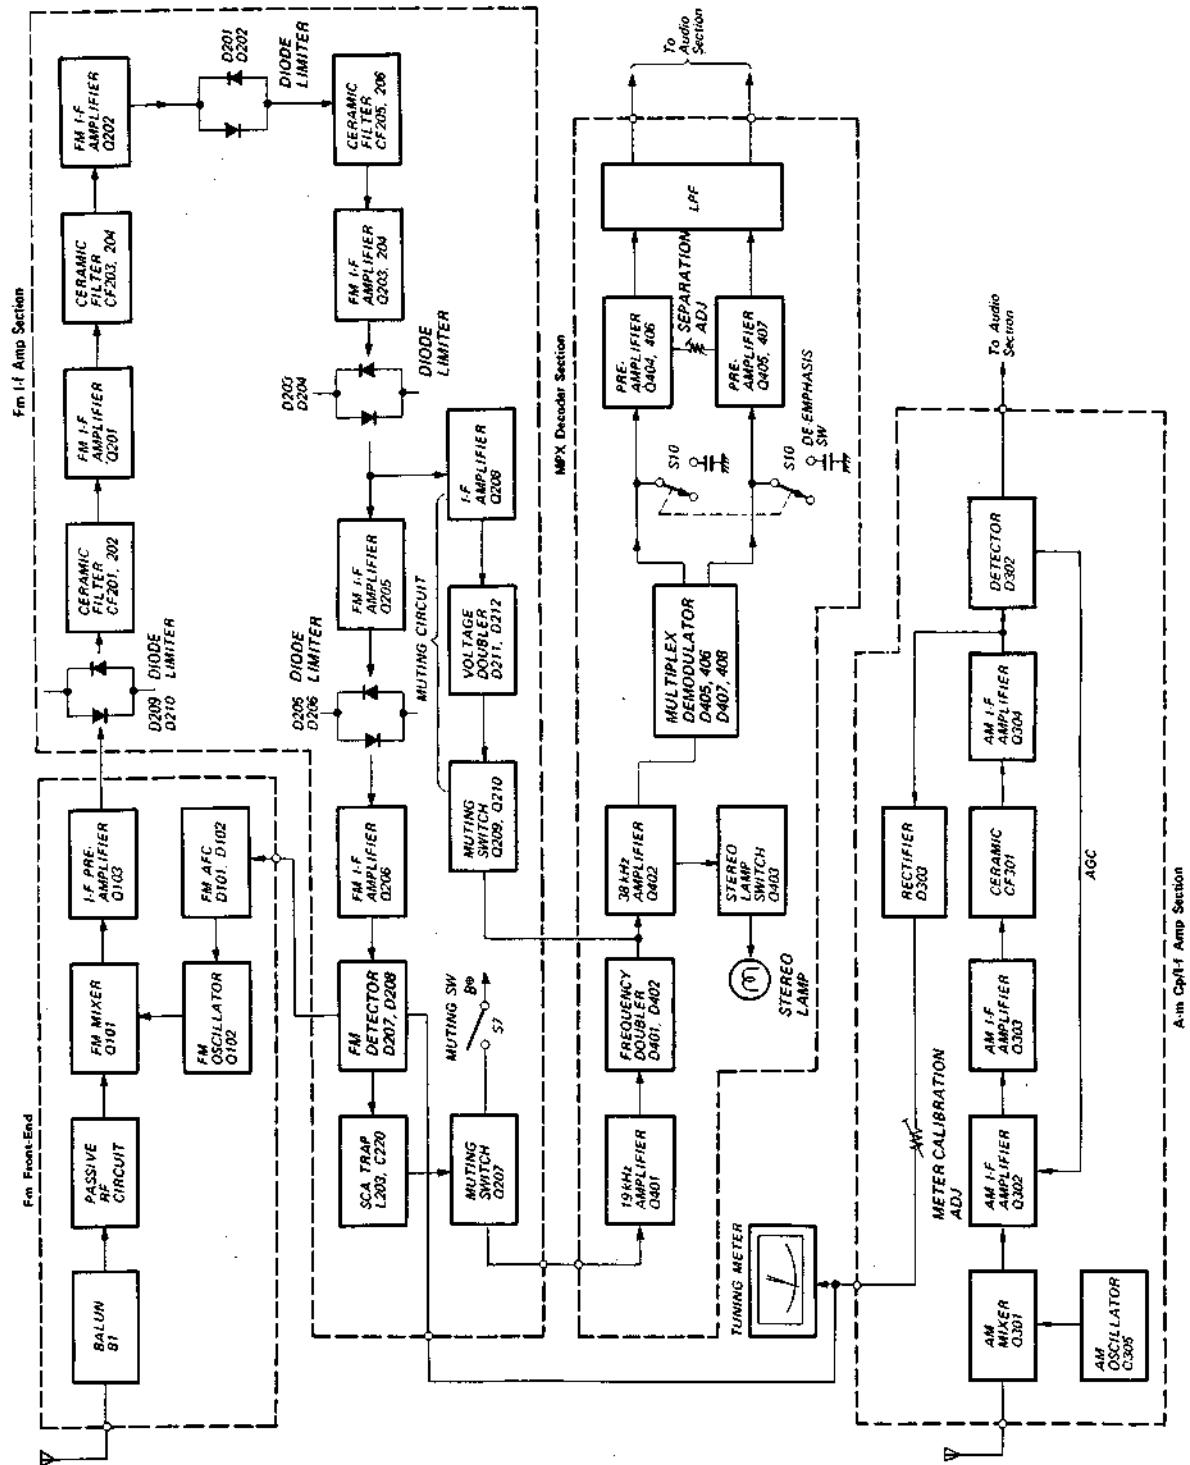

Rectifier
D802

A half-wave rectifier (D802) and ripple filter (C809, R801, R802 and C810) supply well-filtered dc power to the preamplifier section.

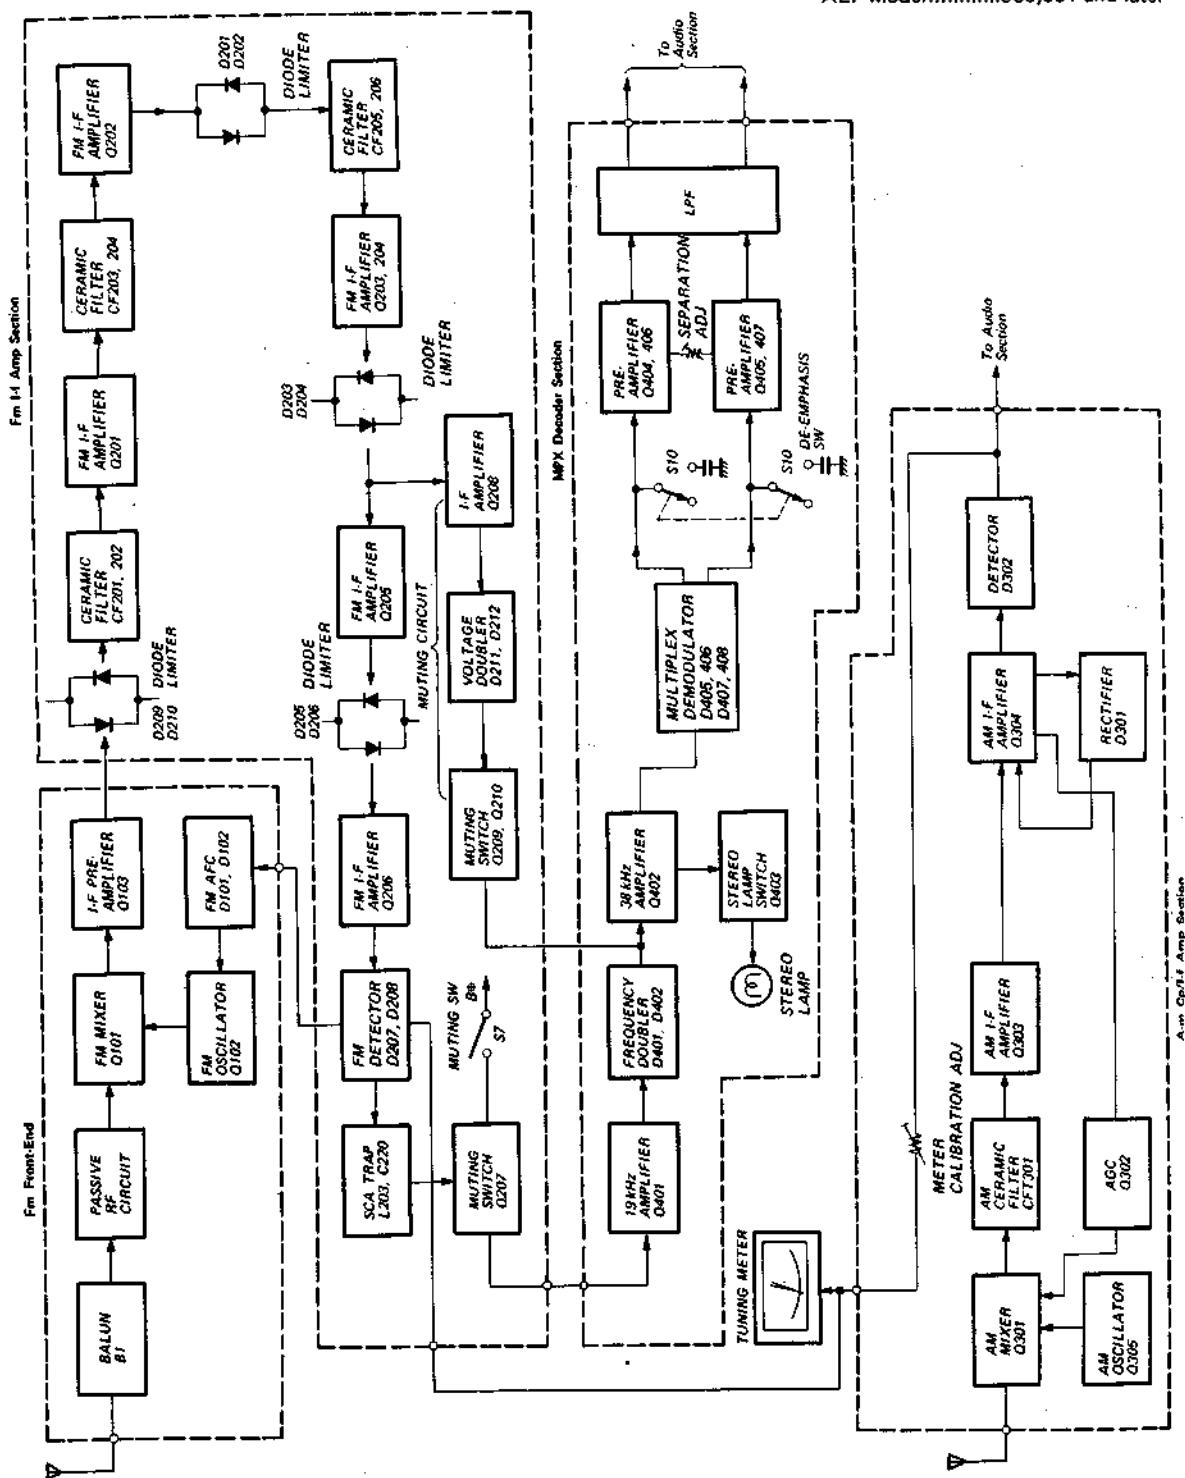

<u>Stage/Control</u>	<u>Function</u>	<u>Stage/Control</u>	<u>Function</u>
Ripple filter Q711 R741, R740 C714, C713 Q761, R791 R790, C764, C763	These components reduce the ripple voltages in the dc power supply for the preamplifier and driver stages of the power amplifier section to an extremely-low value. Q711 and Q761 serve as an electronic filter to supply well filtered dc voltages of about $\pm 37V$ to each stage.	Voltage regulator Q801, D803, D804	Dc output from the rectifier is filtered by C807 and applied to series regulator Q801. Since the voltage at the base of Q801 is kept constant by means of zener diodes D803 and D804, the emitter voltage remains constant regardless of load or line-voltage variations. The regulated and well filtered output of 15V is supplied to the tuner section.

Note: Signal voltages are measured with an ac VTVM
and expressed in dB referred to 0.775V, 1 kHz.

SECTION 2

DISASSEMBLY AND REPLACEMENT

WARNING

Unplug the ac power cord before starting any disassembly or replacement procedures.

2-1. TOOLS REQUIRED

The following tools are required to perform disassembly and replacement procedures on the STR-6055.

1. Screwdriver, Phillips-head
2. Screwdriver, $\frac{1}{8}$ " blade (3 mm)
3. Pliers, long-nose
4. Diagonal cutters
5. Wrench, adjustable
6. Tweezers
7. Electric drill
8. Drill bits
9. Prick punch
10. Hammer, ball-peen
11. Soldering iron, 40 ~ 150 watts
12. Solder, rosin core
13. Cement solvent
14. Contact cement
15. Thermal compound or silicone grease

2-2. HARDWARE IDENTIFICATION GUIDE

The following chart will help you to decipher the hardware codes given in this service manual.

Note: All screws in the STR-6055 are manufactured to the specifications of the International Organization for Standardization (ISO). This means that the new and old screws are not interchangeable because ISO screws have a different number of threads per mm compared to the old ones. The ISO screws have an identification mark on their heads as shown in Fig. 2-1.

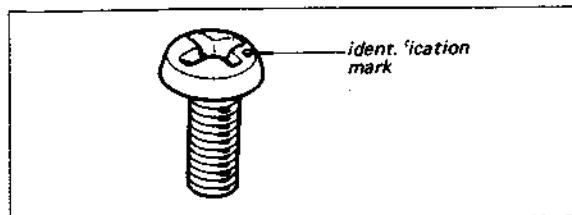

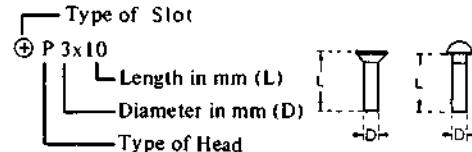

Fig. 2-1. ISO screw

— Hardware Nomenclature —

P	— Pan Head Screw	◆	
PS	— Pan Head Screw with Spring Washer	◆	
K	— Flat Countersunk Head Screw	◆	
B	— Binding Head Screw	◆	
RK	— Oval Countersunk Head Screw	◆	
T	— Truss Head Screw	◆	
R	— Round Head Screw	◆	
F	— Flat Fillister Head Screw	◆	
SC	— Set Screw	◆	
E	— Retaining Ring (E Washer)	◎

— Example —

2-3. TOP COVER AND BOTTOM PLATE REMOVAL

1. Remove the two machine screws at each side of the receiver, and lift off the top cover.
2. Remove the six self-tapping screws ($\oplus B 3 \times 6$) at the bottom of the receiver and pull the bottom plate in the direction indicated by the arrow in Fig. 2-2.

2-4. FRONT PANEL REMOVAL

1. Remove the top cover as described in Procedure 2-3.
2. Pull all the knobs off.

3. Remove the two screws ($\Phi B 3 \times 6$) and two hex-nuts securing the front panel to the front subchassis as shown in Fig. 2-3. Place a piece of cardboard or cloth between the wrench and front panel to avoid marring the panel as shown in Fig. 2-4. Now the front panel is free for servicing.

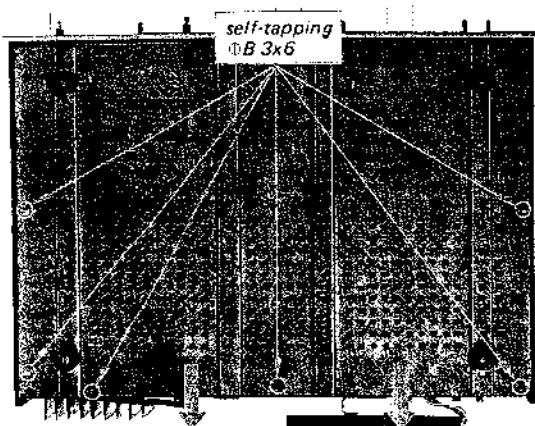

Fig. 2-2. Bottom plate removal

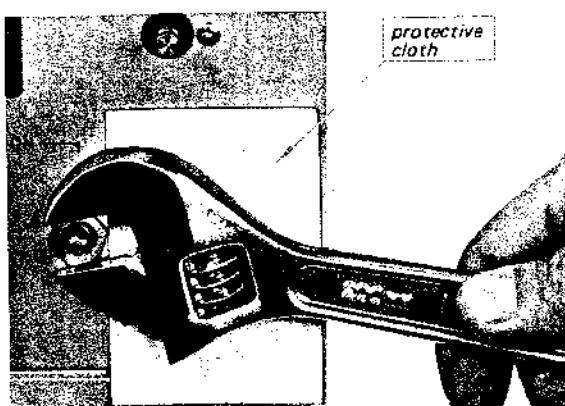

Fig. 2-4. Hex nut removal

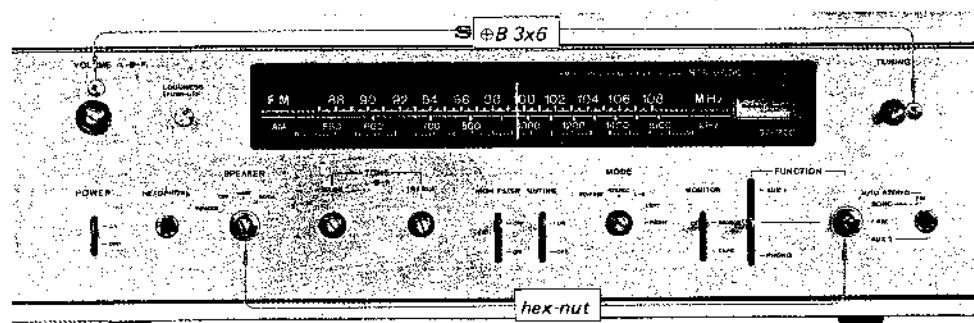

Fig. 2-3. Front panel removal

2-5. DIAL CORD RESTRINGING

Preparation

1. Remove the top cover as described in Procedure 2-3.
2. Cut a 1,500 mm (59") length of dial cord.
3. Tie the end of the cord to a spring as shown in Fig. 2-5.
4. Rotate the tuning-capacitor drive drum fully clockwise (minimum capacitance position).

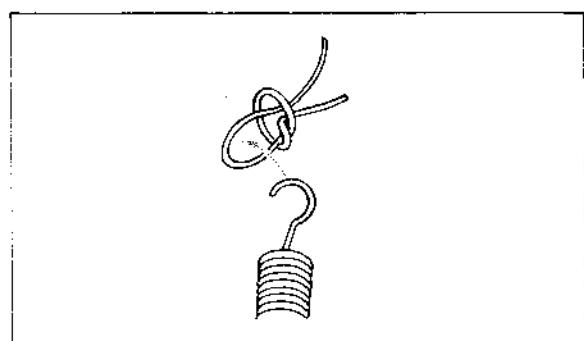

Fig. 2-5. Tying square knot to the coil spring

Procedure

While referring to Fig. 2-6, proceed as follows:

1. Hook the spring to one hole of the drive drum as shown in Fig. 2-7.
2. Run the cord through the slot in the rim of the drum and wrap a half clockwise turn in the inner groove.
3. Run the cord over pulley "A", and then wrap two counterclockwise turns around the tuning shaft.

4. Run the cord over pulleys "B", "C" and "D", then wrap two clockwise turns around the drum from outer groove to inner groove as shown in Fig. 2-8.
5. Pass the doubled end of the cord through the eyelet, then hook it to the spring as shown in Fig. 2-9.

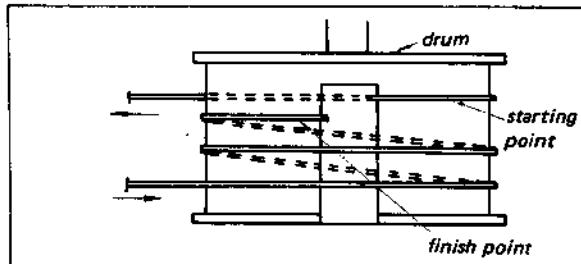

Fig. 2-8. Wrapping the dial cord

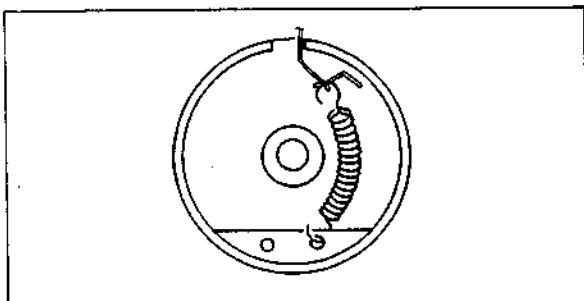

Fig. 2-7. Coil spring installation

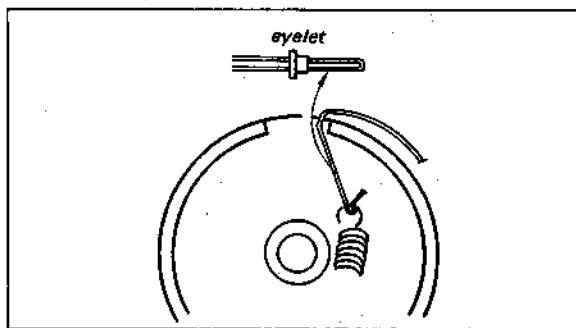

Fig. 2-9. Finishing dial cord stringing

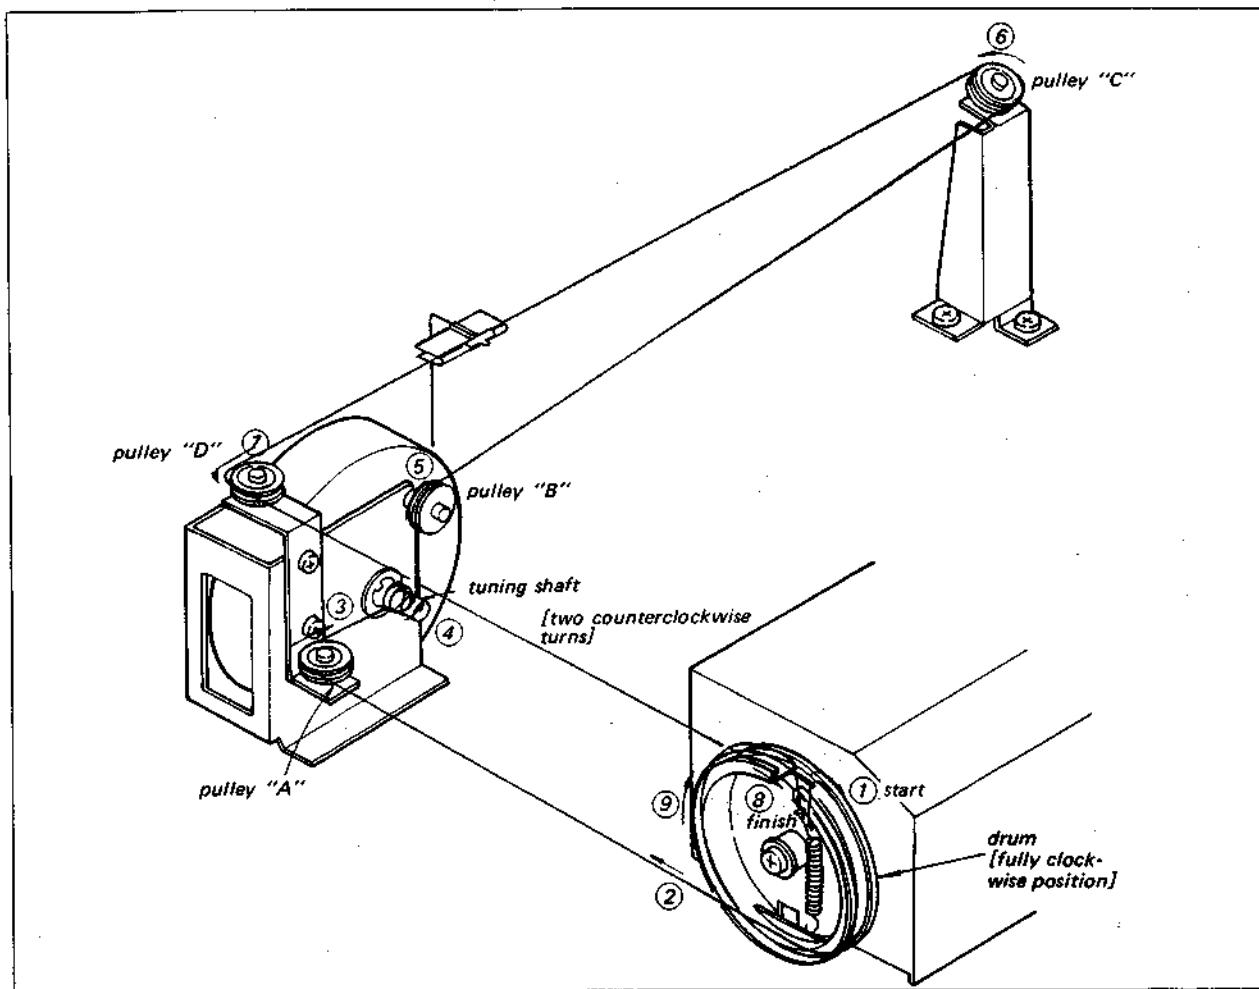

Fig. 2-6. Dial cord stringing

6. Tighten the cord, then squeeze the eyelet so that the spring is under tension. Make a knot at the cord end to keep it from slipping out of the eyelet.
7. After completing the dial-cord stringing, make sure that the tuning system works properly. Apply a drop of contact cement to the finish point.
8. Perform the mechanical dial calibration by following the procedure 2-6.

2-6. MECHANICAL DIAL CALIBRATION

Note: This is required after replacing the dial cord, dial scale or front-end assembly.

1. Put the dial pointer on the cord as shown in Fig. 2-10 and move it to a position where the pointer coincides with the left gap on the dial scale as shown in Fig. 2-11, when the tuning capacitor is set to the maximum capacitance.
2. Apply a drop of contact cement to the tab of the dial pointer.

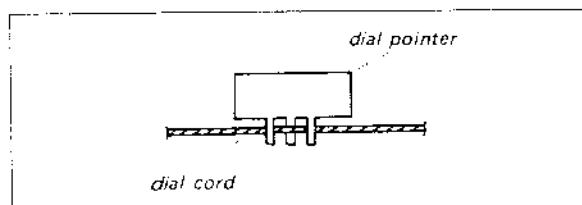

Fig. 2-10. Dial pointer installation

2-7. DIAL SCALE REPLACEMENT

1. Remove the top cover as described in Procedure 2-3.

2. Remove the front panel as described in Procedure 2-4.
3. Remove the two screws ($\ominus P 2.6 \times 4$) securing the dial-scale holder to the front subchassis as shown in Fig. 2-12.
4. Remove the defective dial scale, and then install the replacement scale.

2-8. PILOT LAMP REPLACEMENT

Prepare for replacement any of the pilot lamps by removing the top cover as described in Procedure 2-3.

Meter Lamp

1. Straighten the tab of the meter-lamp holder to permit the removal of the meter-lamp socket.
2. Pull out the meter-lamp socket, and then unscrew the lamp from the socket and install the new lamp.

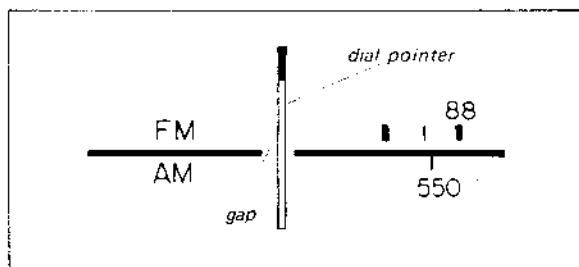

Fig. 2-11. Mechanical dial calibration

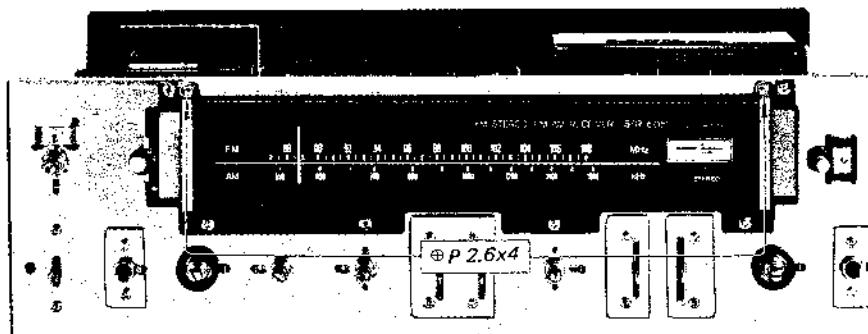

Fig. 2-12. Dial scale removal

Stereo Lamp

1. Remove the two self-tapping screws ($\phi B 3 \times 6$) securing the meter holder to the chassis as shown in Fig. 2-13.

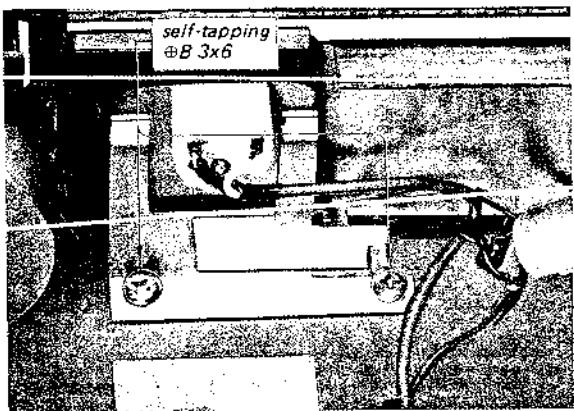

Fig. 2-13. Meter holder and stereo lamp removal

2. Pull the lamp from its holder with tweezers.
3. Cut the lamp leads and solder the lead wires to the new lamp as shown in Fig. 2-14.
4. Wrap the soldered connections with electrical tape as shown in Fig. 2-14.
5. Install the new lamp in its holder.

Dial Lamp

1. Remove the front panel as described in Procedure 2-4.
2. Pry out the fiber lamp shade, and then remove the lamp.

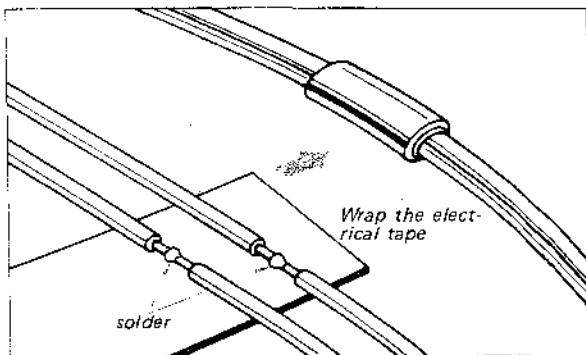

Fig. 2-14. Stereo lamp replacement

2-9. TUNING METER REPLACEMENT

1. Remove the top cover as described in Procedure 2-3.
2. Unsolder the leads from the defective meter.
3. Remove the two self-tapping screws ($\phi B 3 \times 6$) securing the meter holder to the chassis as shown in Fig. 2-13.
4. Remove the meter, and install a new one.

2-10. CONTROL AND SWITCH REPLACEMENT

Prepare for replacing any of the controls or switches by removing the top cover and the front panel as described in Procedures 2-3 and 2-4. Refer to Fig. 2-15.

TONE Controls

1. Apply a drop of cement solvent to the ring spacer on the TREBLE control. Wait a few seconds for the cement to dissolve, and pry out the spacer with a screwdriver.

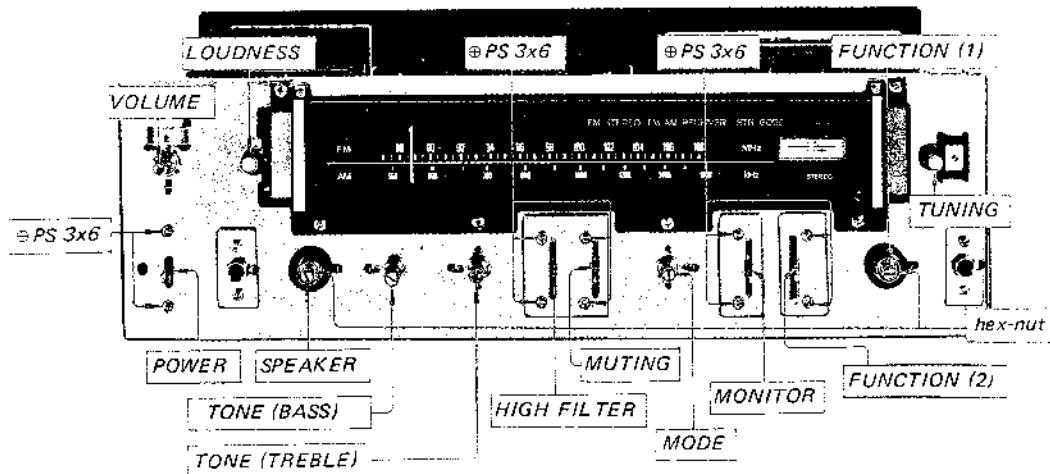

Fig. 2-15. Control and switch replacement

2. Remove the hex nuts that secure the BASS and TREBLE controls to the front-subchassis.
3. Carefully remove them along with the tone-control circuit board.
4. Cut each lug of the defective control on the board to remove the part.
5. Unsolder and remove the clipped lugs, and clean out the holes of the circuit board.
6. Install the replacement control.

POWER, HIGH FILTER, MUTING, MONITOR, FUNCTION (2) Switches

1. Remove the two screws (\oplus PS 3x6) securing switches to the front subchassis as shown in Fig. 2-15.
2. Unsolder the lead wires from the defective switch, and then install the replacement switch.

SPEAKER, MODE, FUNCTION (1) Switches

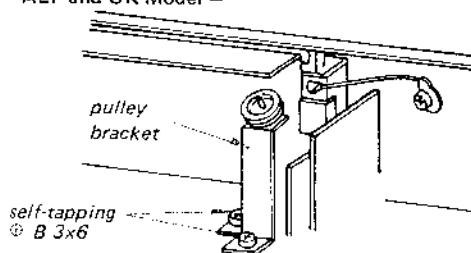

1. Apply a drop of cement solvent to the ring spacer on the switches. Wait a few seconds for the cement to dissolve, and pry out the spacer with a screwdriver.
2. Remove the hex nuts that secure the switches to the front-subchassis as shown in Fig. 2-15.
3. Unsolder the lead wires from the defective switch, and then install the replacement switch.

LOUDNESS Switch

1. Fasten the dial cord to the drum with cellophane tape.

2. Remove the two self-tapping screws (\oplus B 3x6) (■) or two screws (\oplus B 3x6) (●) securing the dial pulley bracket to the chassis as shown in Fig. 2-16.
- Note:** ■ (AEP and UK Model)
● (USA, Canada and EP Model)
3. Put the bracket aside, and then remove the screw (\oplus B 2.6x4) securing the loudness switch to the front subchassis.
 4. Remove it along with the loudness control board, and then install the replacement switch or replacement mounted circuit board including loudness switch (Part No. X-48030-23-0).

- AEP and UK Model -

- USA, Canada and EP Model -

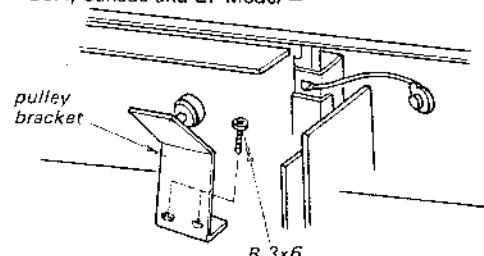

Fig. 2-16. Dial pulley bracket removal

2-11. REAR PANEL REMOVAL

1. Remove the top cover and bottom plate as described in Procedure 2-3.

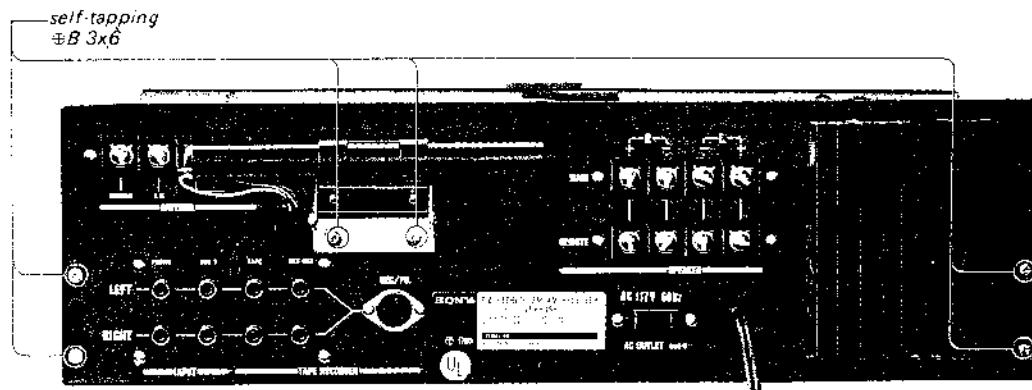

Fig. 2-17. Rear panel removal

2. Unsolder the lead wire connecting between ground terminal and chassis.
3. Unsolder the coaxial cable from fm antenna terminal.
4. Remove the six self-tapping screws ($\Phi B 3 \times 6$). two of them secure the bar antenna holder to the chassis along with rear panel and others secure the rear panel to the chassis as shown in Fig. 2-17. This frees the rear panel.

2-12. REPLACEMENT OF COMPONENTS SECURED TO THE REAR PANEL BY RIVETS

1. Remove the rear panel as described in Procedure 2-11.
2. Bore out the rivets using a drill bit slightly larger in diameter than the rivet. See Fig. 2-18.

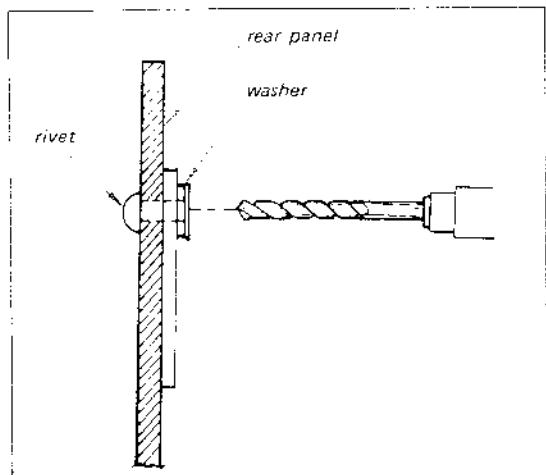

Fig. 2-18. Rivet replacement

3. Punch out the remainder of the rivet with a nail set or prick punch.
4. Remove the defective component, and install the new one.
5. Secure the new component with a suitable screw and nut, or a repair rivet screw (Part No. 3-701-402-00).

2-13. POWER TRANSISTOR REPLACEMENT

1. Remove the top cover and bottom plate as described in Procedure 2-3.
2. Remove the four self-tapping screws ($\Phi B 3 \times 8$) securing the heat sink to the chassis as shown in Fig. 2-19.

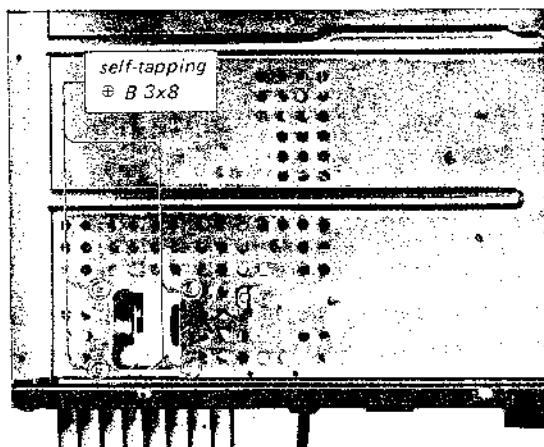

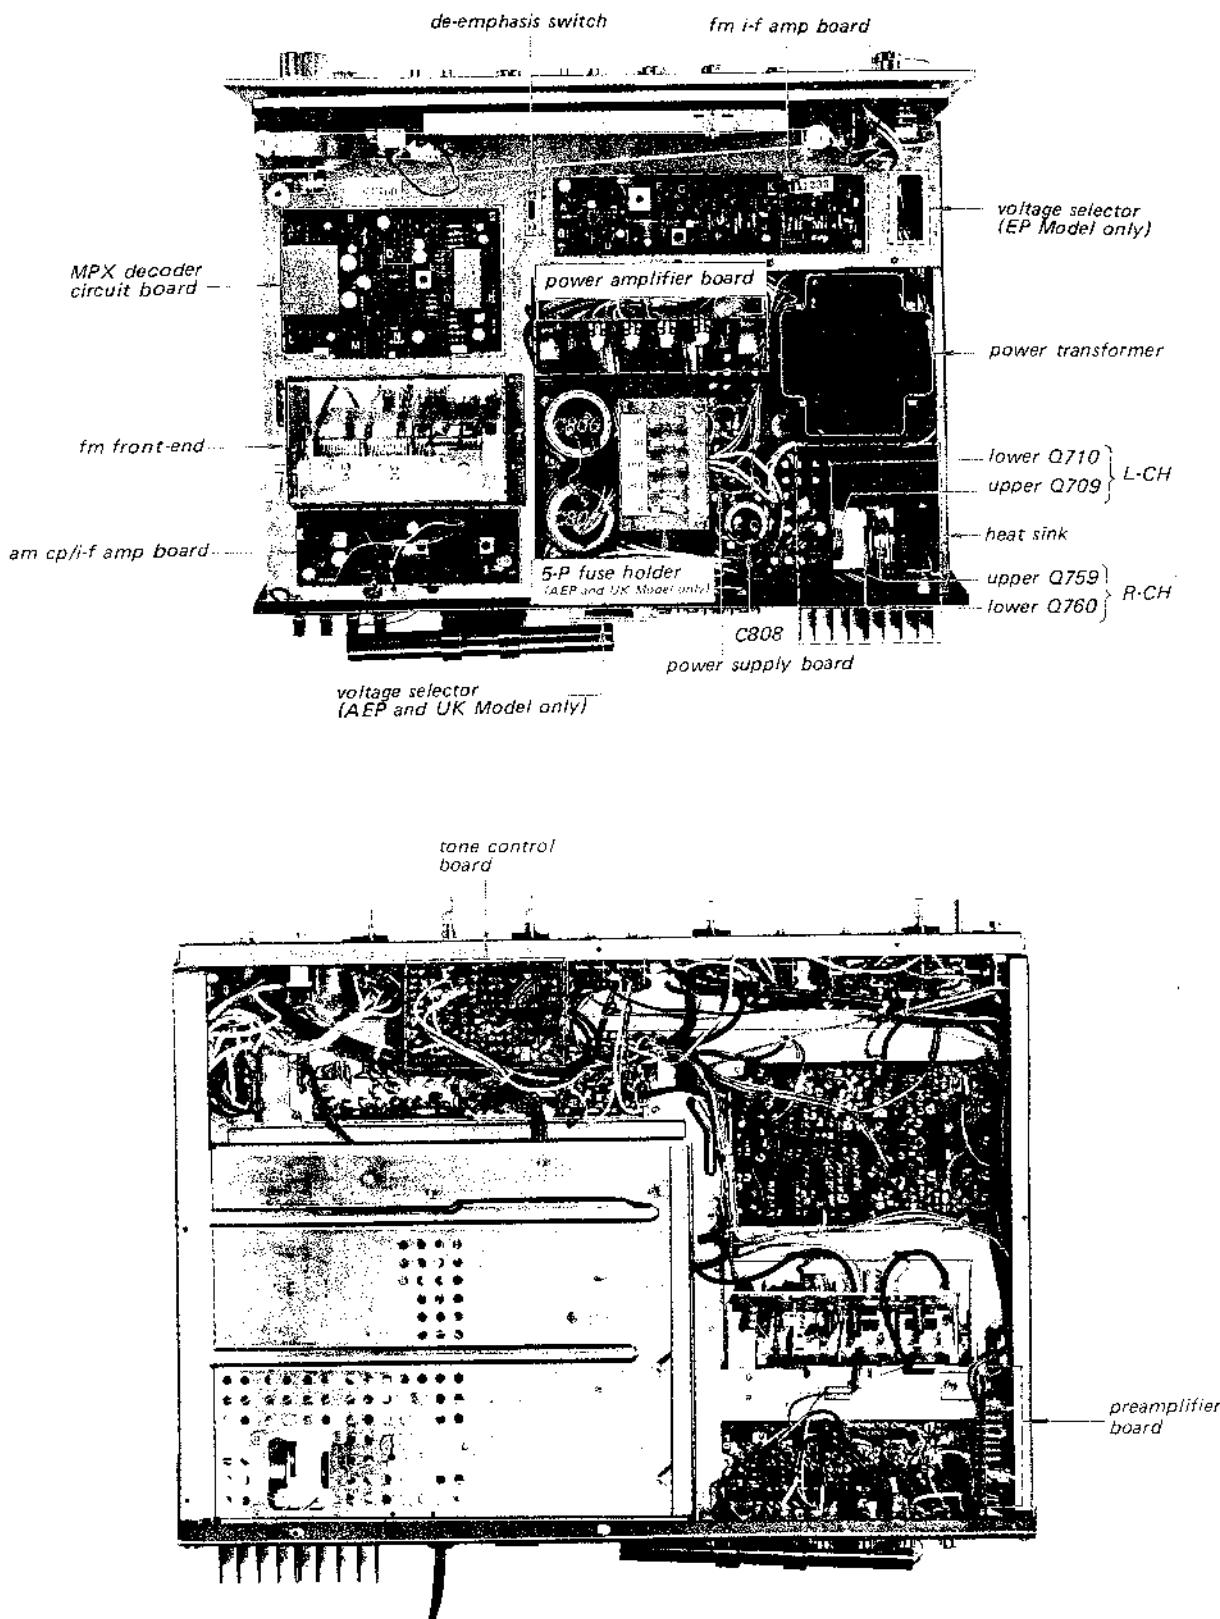

Fig. 2-19. Heat sink removal

3. Cut the emitter and base leads of the defective power transistor with a diagonal cutter. This prevents damage to the mica insulator when removing the defective power transistor.
4. Carefully draw back the heat sink, and then remove the two screws ($\Phi B 3 \times 12$) and nuts securing the power transistor to the heat sink.
5. When replacing the power transistor, apply a coating of a thermal compound or a heat-transferring grease to both sides of the mica insulator. Any excess compound or grease squeezed out when the mounting screws are tightened should be wiped off with a clean cloth. This prevents accumulation of conductive dust particles that might eventually cause a short.

2-14. CHASSIS LAYOUT

SECTION 3 ALIGNMENT AND ADJUSTMENT

3-1. FM I-F STRIP ALIGNMENT

CAUTION

The ceramic filters in the fm i-f circuit are selected according to their specified center frequencies and color coded as shown in Fig. 3-1 and listed in Table 3-1. Check the color code of the filters to identify the same center frequency when replacing any of these filters.

TABLE 3-1. FM I-F CERAMIC FILTERS

Part No.	Color	Specified Center Freq.
1-403-562-11	red	10.70 MHz
1-403-562-21	black	10.66 MHz
1-403-562-31	white	10.74 MHz
1-403-562-41	green	10.62 MHz
1-403-562-51	yellow	10.78 MHz

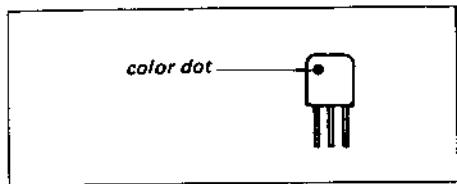

Fig. 3-1. Fm i-f ceramic filter

Signal Generator Alignment

Test Equipment Required

1. Fm signal generator
2. Ac VTVM
3. Oscilloscope
4. Alignment tools
5. Headphone (8Ω)

Note: This alignment is needed only after IFT101 in the front-end, if trimmer capacitors (CT102, CT103), or T201 (discriminator transformer) has been replaced or repaired.

All signal generator output levels specified in the fm section are for terminated output.

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Insert a headphone plug to the HEADPHONE jack.
3. Connect the input cable of the ac VTVM to the REC OUT jack (J504).
4. Connect the signal-generator output to the fm antenna terminal as shown in Fig. 3-2.
5. Short the connection point of R241 and C215 (AFC circuit) to ground as shown in Fig. 3-3.

Procedure

1. With the equipment connected as shown in Fig. 3-2, set the signal-generator controls as follows:
 - Carrier frequency 98 MHz
 - Modulation Fm, 400 Hz, 75 kHz deviation (100%)
 - Output level 30 µV (30 dB)
2. Set the receiver controls as follows:
 - FUNCTION switch FM MONO
 - MODE switch STEREO
 - VOLUME control Minimum
3. Turn the core of transformer IFT101 or T201 (bottom core) (see Fig. 3-3 or Fig. 3-5) with the alignment tool to obtain maximum output.

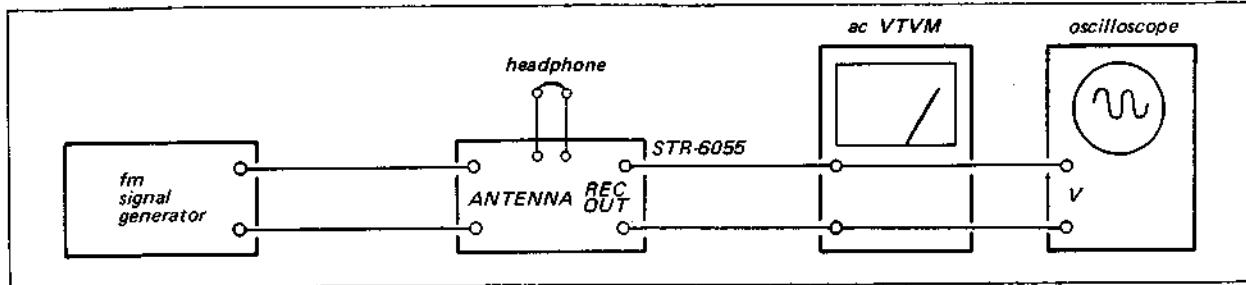

Fig. 3-2. Fm i-f, muting and front-end alignment test setup

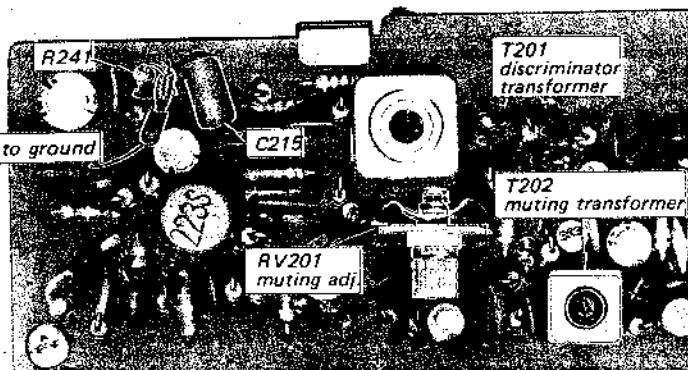

Fig. 3-3. Interruption of afc circuit and parts location

3-2. FM DISCRIMINATOR ALIGNMENT

Note: There are two or three methods of discriminator alignment, but only the simplified method using the receiver's TUNING meter is described here.

Test Equipment Required

1. Oscilloscope
2. Alignment tools
3. Headphone (8Ω)

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Connect the input cable of the oscilloscope to REC OUT jack (J504) as shown in Fig. 3-4.
3. Short the connection point of R241 and C215 (AFC circuit) to ground as shown in Fig. 3-3.
4. Insert a headphone plug to the HEADPHONE jack.

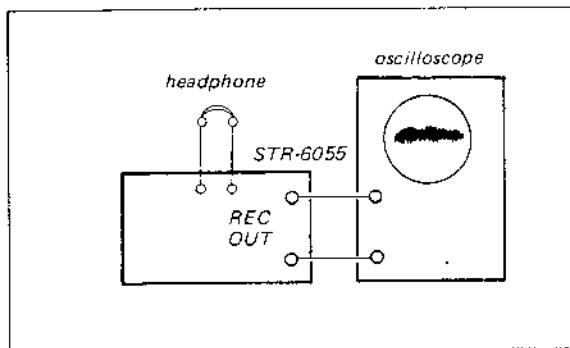

Fig. 3-4. Discriminator alignment test setup

Procedure

1. With the equipment connected as shown in Fig. 3-2, set the receiver controls as follows:
FUNCTION switch FM MONO
MODE switch STEREO
No signal should be received.
2. Adjust the controls of the oscilloscope to provide a visible indication of noise. Always watch the oscilloscope to confirm that the tuner is not receiving any off-the-air signals.
3. Turn the top core (secondary side) of discriminator transformer T201 (see Fig. 3-3) with a hex-head alignment tool to obtain a null-point reading on the TUNING meter. If the discriminator transformer (T201) is not aligned correctly, some deviation on the TUNING meter will be observed.

Note: Turn the core carefully and slowly. At both extreme positions of the top core, a null point will be observed. The real null point should be obtained in the middle of the core thread length.

4. Repeat the above mentioned steps and fm i-f strip alignment two or three times.

3-3. MUTING ADJUSTMENT

Note: Two methods of muting adjustment are available, signal generator adjustment and adjustment by using an off-the-air signal. You can use either of them.

Signal Generator Adjustment

Test Equipment Required

1. Fm signal generator
2. Ac VTVM or oscilloscope
3. Alignment tool

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Turn RV201 (see Fig. 3-3) fully clockwise on the fm i-f amp board.
3. Short the connection point of R241 and C215 (AFC circuit) to ground as shown in Fig. 3-3.

TABLE 3-2 MUTING ADJUSTMENT

Coupling Between Receiver and SG	SG Frequency and Output Level	Dial Indication	Adjust	Remarks
Direct	98 MHz 400 Hz, 30% Mod.	98 MHz	T202 See Fig. 3-3	Turn the core of T202 to obtain proper muting operation.

Procedure

- With the equipment connected as shown in Fig. 3-2, set the receiver controls as follows:
 FUNCTION switch FM MONO
 MODE switch STEREO
 MUTING switch ON
- Follow the procedure given in Table 3-2. Note that the muting circuit should begin to operate at the symmetrical deflection point of TUNING meter when detuning the tuner to higher or lower than the reference carrier frequency.

Off-the-Air Signal Adjustment

Accurate muting circuit adjustment can also be performed by utilizing off-the-air local fm signals instead of the fm signal generator.

Note that a weak signal is best for this purpose.

front-end section of the tuner has been carefully adjusted at the factory, so very little adjustment is necessary in the field. Alignment need not be performed when the front-end FET is replaced since changes in FET parameters have little effect upon tuning. If an rf-stage adjustment is required, ask your nearest SONY Service Station to send your unit to the Factory Service Center for a complete front-end alignment.

Exercise caution when returning the faulty unit so that it will not be damaged during transit. The warranty will not cover damage incurred in transit to the Factory Service Center.

Note: Before starting this alignment, the discriminator-transformer alignment should be performed.

3-4. FM FREQUENCY COVERAGE ALIGNMENT**CAUTION**

Never attempt alignment of the front-end section except for the frequency-coverage and dial-calibration adjustments. The

Signal Generator Alignment**Test Equipment Required**

- Fm signal generator
- Ac VTVM
- Alignment tools

TABLE 3-3 FM FREQUENCY COVERAGE ALIGNMENT

Step	Coupling Between Receiver and SG	SG Frequency and Output Level	Dial Indication	Ac VTVM Connection	Adjust	Indication
1	Direct	87.5 MHz 400 Hz 100% Mod. as low as possible	87.5 MHz	REC OUT (J504)	OSC coil L104 See Fig. 3-5	Maximum VTVM reading
2		108 MHz 400 Hz 100% Mod. as low as possible	108 MHz		OSC trimmer CT104 See Fig. 3-5	

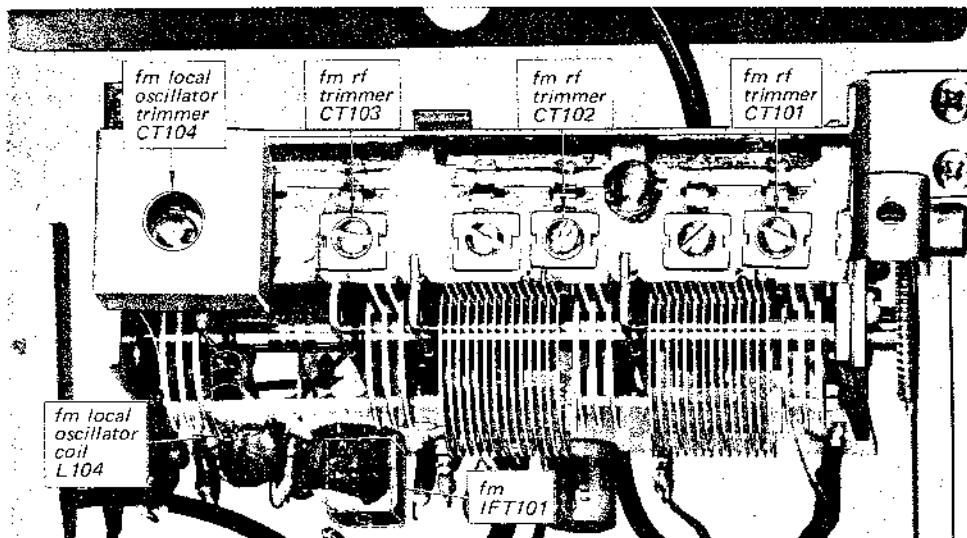

Fig. 3-5. Adjustment parts location

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Connect the equipment as shown in Fig. 3-2.
3. Set the receiver controls as follows:
FUNCTION switch FM MONO
MODE switch STEREO
4. Short the connection point of R241 and C215 (AFC circuit) to ground as shown in Fig. 3-3.

Procedure

Follow the procedures given in Table 3-3 when performing this alignment with an fm signal generator. Be sure that the dial is mechanically calibrated as described in Procedure 2-6 on page 19.

Off-the-Air Signal Alignment

An accurate frequency-coverage alignment can also be performed by utilizing off-the-air local fm signals. However, before performing the following procedure, be sure that the dial pointer is correctly positioned as described in Procedure 2-6 on page 19.

Test Equipment Required

1. Alignment tools

Procedure

1. Short the connection point of R241 and C215 (AFC circuit) to ground as shown in Fig. 3-3.
2. Tune the receiver to the lowest frequency station.
3. Check the dial scale for a calibration accuracy of ± 200 kHz from the carrier frequency of the

station. If the dial-accuracy deviation exceeds this limit, turn the local-oscillator coil L104 (see Fig. 3-5) slightly until optimum dial calibrations is obtained.

4. Tune the receiver to the highest-frequency station in your locality. If the dial-calibration error is excessive, adjust local-oscillator trimmer CT104 (see Fig. 3-5) to obtain maximum calibration accuracy.
5. Repeat steps 3 and 4.

3-5. FM STEREO SEPARATION ADJUSTMENT**Test Equipment Required**

1. Fm stereo signal generator
2. Ac VTVM
3. Oscilloscope

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Connect the test equipment as shown in Fig. 3-6, then set the fm stereo signal generator controls as follows:

Carrier frequency	98 MHz
Output level	$1,000 \mu\text{V}$ (60 dB)
Mode	STEREO
Audio (400 Hz) Mod.....	67.5 kHz (90%)*
Pilot (19 kHz) Mod	7.5 kHz (10%)

*Note: 75 kHz (100%) if the metering indicates total modulation (audio-pilot).

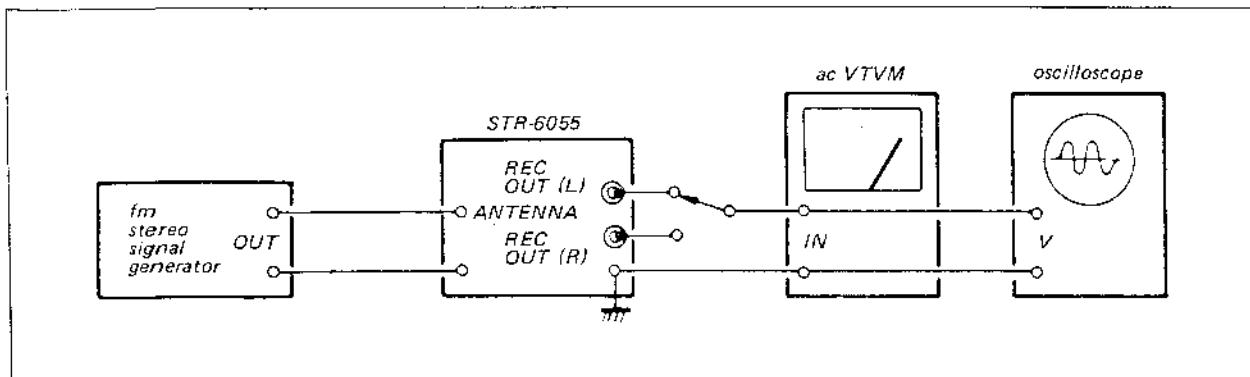

Fig. 3-6. Fm stereo separation adjustment test setup

Procedure

- Precisely tune the set to the carrier frequency of stereo signal generator, then turn the top core of switching transformer T401 (see Fig. 3-7) to obtain maximum output at the left channel. Note that this adjustment has a close relationship with stereo distortion.
- Record the output level of the left channel when the stereo signal generator input selector is set to the left channel.
- Switch the stereo signal generator input selector to the right channel and read the residual signal level in the left channel.
- The output-level to residual-level ratio represents the separation. Adjust separation adj. control RV401 (see Fig. 3-7) for minimum residual level. Check the right channel for separation. Usually, about an 8 to 9 dB difference in channel separation exists. Readjust RV401 for minimum difference between left- and right-channel separation. While doing this, remember that the output level also changes according to the setting of RV401.

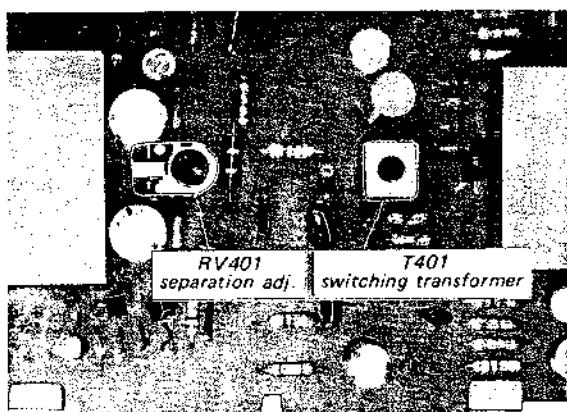

Fig. 3-7. Adjustment parts location

3-6. A-M I-F STRIP ALIGNMENT

Note: No adjustment is required in the field even if after replacing any of i-f transformers (CFT301 or IFT301) for the sets with serial numbers of 810,401 and later (USA Model)
700,301 and later (Canada Model)
553,001 and later (EP Model)
600,001 and later (UK Model)
900,001 and later (AEP Model).

Following procedures should be applied for the sets with serial numbers of
800,001 to 180,400 (USA Model)
700,001 to 700,300 (Canada Model)
550,001 to 553,000 (EP Model).

Preparation

Remove the top cover as described in Procedure 1-3 on page 16. Then set the receiver FUNCTION switch to AM.

Note: To perform this alignment, the local oscillator should be killed. To do this, shunt the local oscillator capacitor with a 0.02μF capacitor as shown in Fig. 3-9.

Sweep Generator Alignment**Test Equipment Required**

1. Sweep generator, 455 kHz
2. Oscilloscope
3. Alignment tools

Procedure

1. Connect the sweep generator output directly to the a-m antenna terminal.
2. Connect the input cable of the oscilloscope to R321 (see Fig. 3-9) and ground on the a-m cp/i-f amp board with alligator clips as shown in Fig. 3-9.
3. Set the sweep generator controls as follows:
Center frequency 455 kHz
Sweep width 25 kHz
Output as low as possible

4. With the equipment connected as shown in Fig. 3-10, adjust the oscilloscope controls and generator output to provide a visible indication.
5. Turn the top core of IFT301 (see Fig. 3-9) to obtain a maximum and symmetrical response as shown in Fig. 3-8.

Fig. 3-8. A-m i-f strip alignment by sweep generator

Procedure

1. Set the rf signal generator controls as follows:
Modulation INTERNAL
Frequency 455 kHz
OUTPUT level 1,000 μ V
2. Connect the rf signal-generator output to a-m antenna terminal.
3. With the equipment connected as shown in Fig. 3-11, turn the top core of IFT301 (see Fig. 3-9) to obtain maximum output.

Rf Signal Generator Alignment

Test Equipment Required

1. Signal generator, 455 kHz, a-m modulation
2. Oscilloscope or VTVM
3. Alignment tools

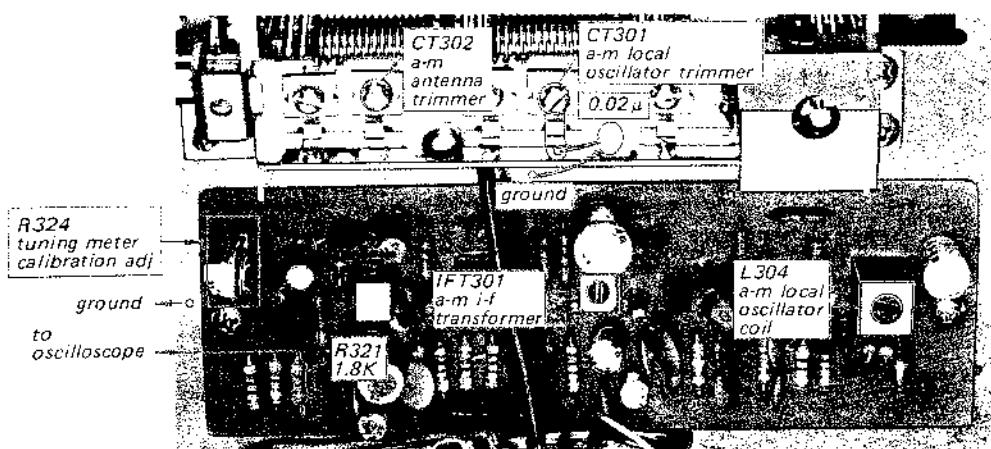

Fig. 3-9. Disabling the a-m local oscillator, a-m detector output connection and adjustment parts location

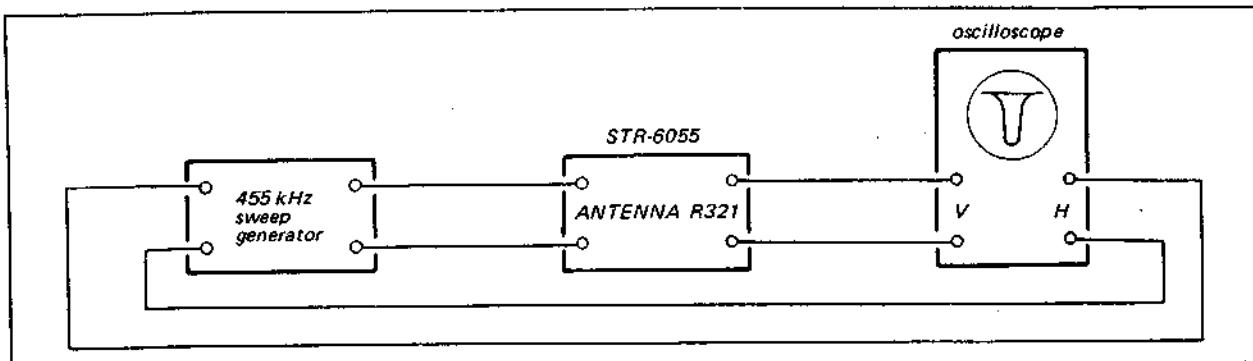

Fig. 3-10. A-m i-f strip alignment test setup by sweep generator

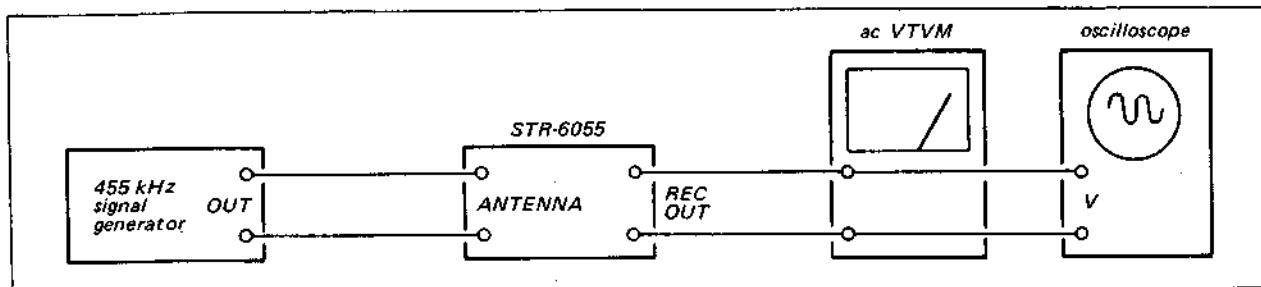

Fig. 3-11. A-m i-f strip alignment test setup by rf signal generator

3-7. A-M FREQUENCY COVERAGE AND TRACKING ALIGNMENT

Preparation

Remove the top cover as described in Procedure 2-3 on page 16. Then, set the FUNCTION switch to AM.

Signal Generator Method

Test Equipment Required

1. A-m signal generator
2. Loop antenna
3. Ac VTVM or oscilloscope

Procedure

With the equipment connected as shown in Fig. 3-12, follow the procedures given in Table 3-4 when performing this alignment with an a-m signal generator.

Off-the-Air Signal Method

An accurate frequency-coverage and tracking alignment can also be performed by utilizing off-the-air local a-m signals. However, before performing the following procedure, be sure that the dial pointer is

correctly positioned as described in the Procedure 2-6 on page 19.

Frequency Coverage Alignment

Note:

- | | | |
|-------------------|------------------------------|-------------------|
| ▲ USA Model | Serial No. up to 810,400 | See Fig.
3-9. |
| Canada Model ... | Serial No. up to 700,300 | |
| EP Model | Serial No. up to 553,000 | |
| USA Model..... | Serial No. 810,401 and later | See Fig.
3-14. |
| Canada Model ... | Serial No. 700,301 and later | |
| EP Model..... | Serial No. 553,001 and later | |
| UK Model | Serial No. 600,001 and later | |
| AEP Model | Serial No. 900,001 and later | |

Procedure

1. Tune the receiver to the lowest-frequency station in your locality. Check the dial scale for a calibration accuracy of ± 20 kHz from the carrier frequency. If the dial calibration error exceeds this limit, turn the local oscillator-coil $L_{304}^{(A)}$ $T_{301}^{(B)}$ slightly until optimum dial calibration is obtained.
2. Tune the receiver to the highest-frequency station in your locality. If the dial calibration error exceeds ± 30 kHz from the carrier frequency, adjust local-oscillator trimmer-capacitor $CT_{301}^{(A)}$ $CT_{302}^{(B)}$ to obtain maximum calibration accuracy. Repeat the above steps two or three times.

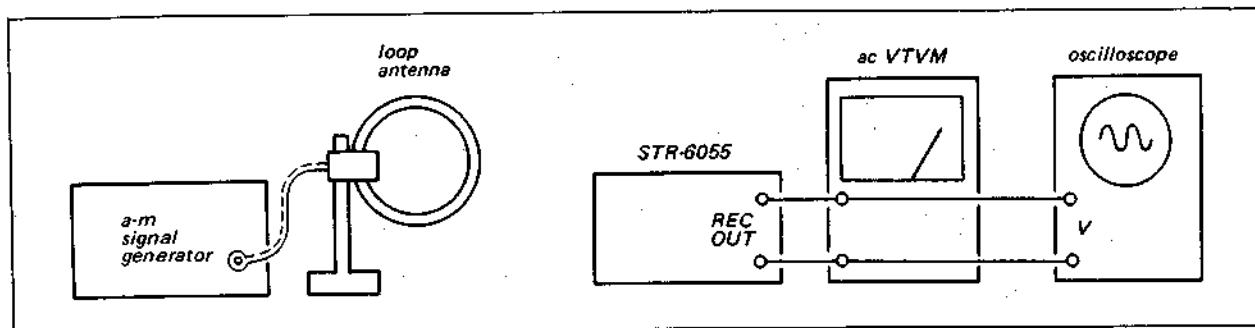

Fig. 3-12. A-m frequency coverage and tracking alignment test setup

Tracking Alignment

1. Tune the set to the station whose carrier frequency is closest to 620 kHz and adjust the position of a-m bar antenna core (see Fig. 3-13) to obtain maximum output.
2. Tune the set to the station whose carrier frequency is closest to 1,400 kHz and adjust antenna trimmer capacitor CT302(^A) to obtain maximum output.
3. Repeat the above steps two or three times.

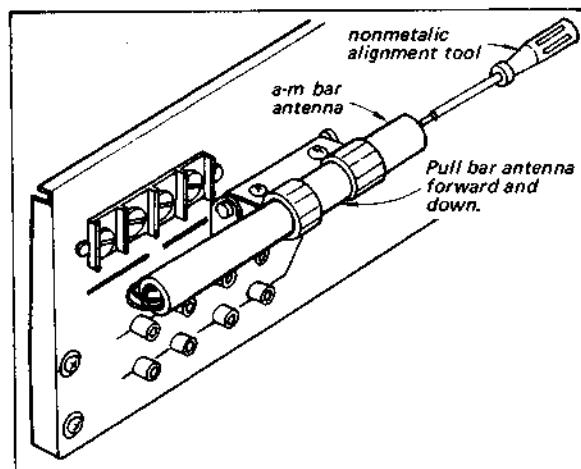

Fig. 3-13. A-m bar antenna core alignment

TABLE 3-4 A-M FREQUENCY COVERAGE AND TRACKING ALIGNMENT

A-M FREQUENCY COVERAGE ALIGNMENT			SG Coupling Loop Antenna SG Output Level 400 Hz, 30% (as low as possible)		
Step	SG Frequency	Dial Indication	Ac VTVM Connection	Adjust	Indication
1	550 kHz	550 kHz	REC OUT	OSC coil L304(^A) T301(^O)	Maximum VTVM reading
2	1,600 kHz	1,600 kHz		OSC trimmer CT301(^A) CT302(^O)	
A-M TRACKING ALIGNMENT			SG Coupling Loop Antenna SG Output Level 400 Hz, 30% (as low as possible)		
1	600 kHz	Tune to the SG signal.	REC OUT	Bar antenna coil L303(^A) L904(^O) (See Fig. 3-13)	Maximum VTVM reading
2	1,400 kHz			Antenna trimmer CT302(^A) CT301(^O)

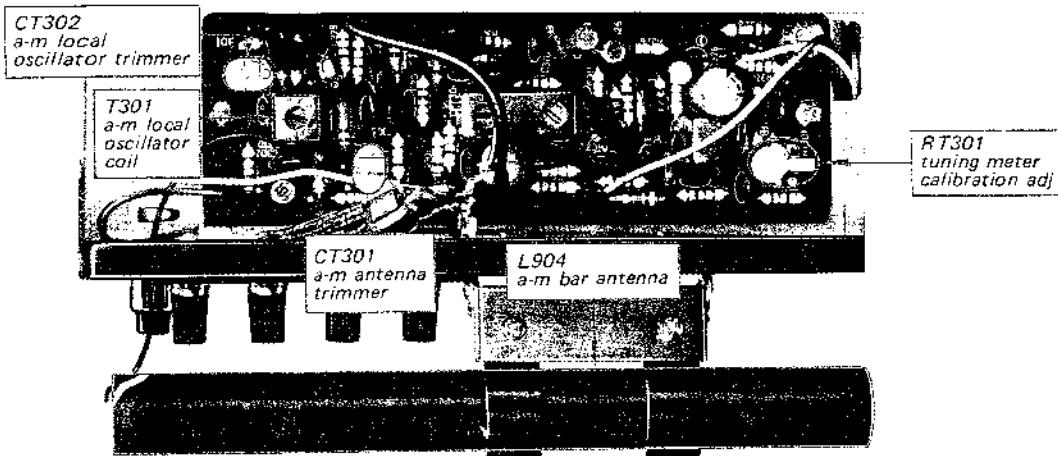

Fig. 3-14. Adjustment parts location

3.8. TUNING METER CALIBRATION

Test Equipment Required

1. Signal generator
2. Ac VTVM
3. Loop antenna
4. Alignment tools

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.

Procedure

1. Connect the test equipment as shown in Fig. 3-15.
2. Set the a-m signal generator and receiver controls as follows:
 - Carrier frequency 1,000 kHz
 - Output level 104 dB/m (160 mV/m)
at a-m bar
antenna
 - Modulation (400 Hz) 30%
 - VOLUME control Minimum
 - FUNCTION switch AM
 - MONITOR switch SOURCE
3. Precisely tune the set to the signal and adjust R324 (RT301) (■) to obtain the meter pointer within 2 mm ($\frac{5}{64}$ "') left of its maximum indication as shown in Fig. 3-16.

^a Note: R324 (see Fig. 3-9)

Applicable Serial Numbers

USA Model Up to 810,400
Canada Model Up to 700,300
EP Model Up to 553,000.

RT301 (see Fig. 3-14)

Applicable Serial Numbers

USA Model 810,401 and later
Canada Model 700,301 and later
EP Model 553,001 and later
UK Model 600,001 and later
AFP Model 900,001 and later

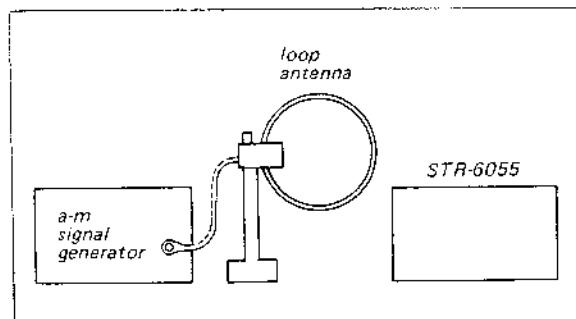

Fig. 3-15. Tuning meter calibration test setup

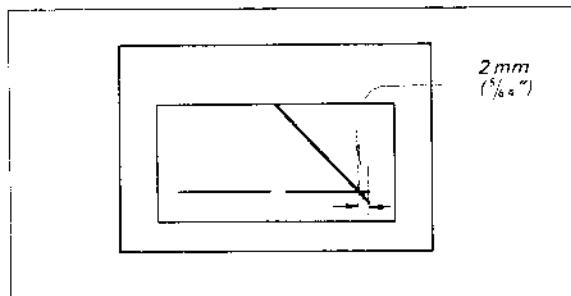

Fig. 3-16. Tuning meter calibration

3-9. POWER AMPLIFIER ADJUSTMENT

Note: There are two adjustment items in the power amplifier. One is dc-bias adjustment and the other is dc-balance adjustment. These adjustments should be repeated alternately two or three times after replacing any of the power transistors until the best operation is obtained.

1. Dc-Bias Adjustment

Serious deficiencies in performance, such as thermal runaway of power transistors, will result if this adjustment is improperly set.

CAUTION

To avoid accidental power transistor damage, increase the ac line voltage gradually, using a variable transformer, while measuring the voltage across emitter of Q709 (Q759) and collector of

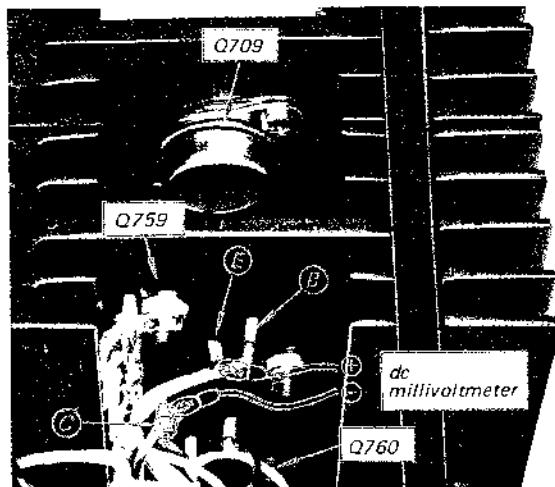

Fig. 3-17. Dc millivoltmeter connection

Q710 (Q760) as shown in Fig. 3-17 and 3-18. Check to see that the reading does not exceed 50 mV. If it does, turn off the power immediately, then check and repair the trouble in the power amplifier board.

Test Equipment Required

1. Dc millivoltmeter
2. Variable transformer
3. Screwdriver with 3 mm ($\frac{1}{8}$ ") blade

Preparation

1. Remove the top cover as described in Procedure 2-3 on page 16.
2. Connect the dc millivoltmeter across emitter of Q709 (Q759) and collector of Q710 (Q760) as shown in Fig. 3-17 and 3-18.
3. Apply a drop of cement solvent to the RV701, RV702, RV751 and RV752 then wait a few seconds for the cement to dissolve.

Procedure

1. Set the adjustable resistors (see Fig. 3-19) on the power-amplifier board as follows:
 RV702 fully
 (L-CH, dc bias) counter-clockwise
 RV752 (R-CH, dc bias) fully clockwise
 RV701, RV751 (dc balance) mid-position
2. Set the variable transformer for minimum output.
3. Turn the POWER switch ON, and then increase the line voltage up to the rated value.

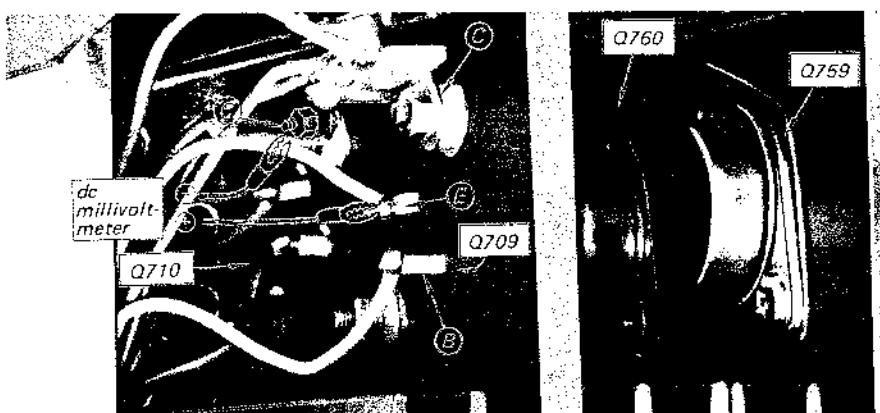

Fig. 3-18. Dc millivoltmeter connection

4. Adjust RV702 and RV752 to obtain a 50 mV reading on the meter, and then perform the dc-balance adjustment.

2. Dc-Balance Adjustment

Excessive harmonic distortion at high levels will result if this adjustment is improperly set.

Test Equipment Required

1. Dc null meter or dc millivoltmeter
2. Screwdriver with 3 mm ($\frac{1}{8}$ ") blade

Preparation

1. Set the SPEAKER switch to MAIN.
2. Connect the dc null meter or dc millivoltmeter to the MAIN speaker output terminal.

Procedure

1. Turn the POWER switch ON, and then adjust RV701 (RV751) for 0V reading on the meter.
2. After 10 minutes warm-up, alternately repeat this and the dc bias adjustment two or three times.
3. After completing the adjustment, apply a drop of lock paint to RV701 and RV702 (RV751 and RV752).

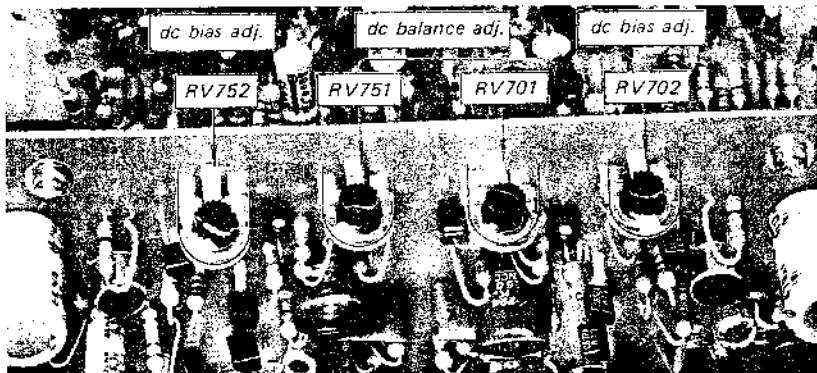

Fig. 3-19. Adjustment parts location

SECTION 4 REPACKING

The STR-6055 original shipping carton and packing material are the ideal container for shipping the unit. However to secure the maximum pro-

tection, the STR-6055 must be repacked in these materials precisely as before. The proper repacking procedures are shown in Fig. 4-1.

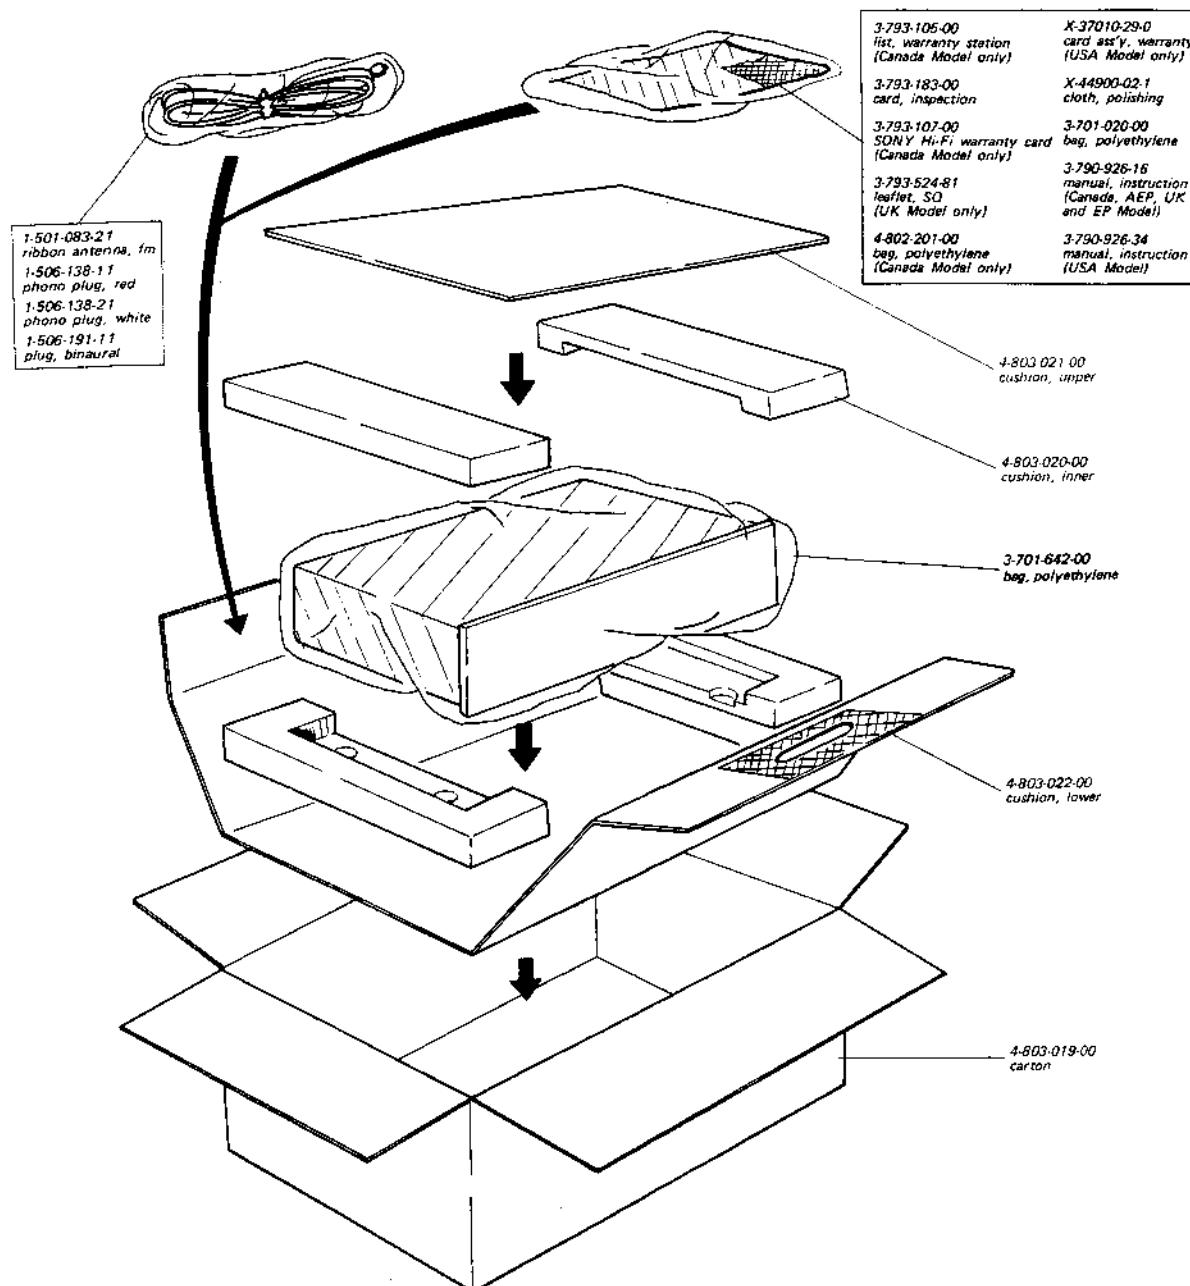

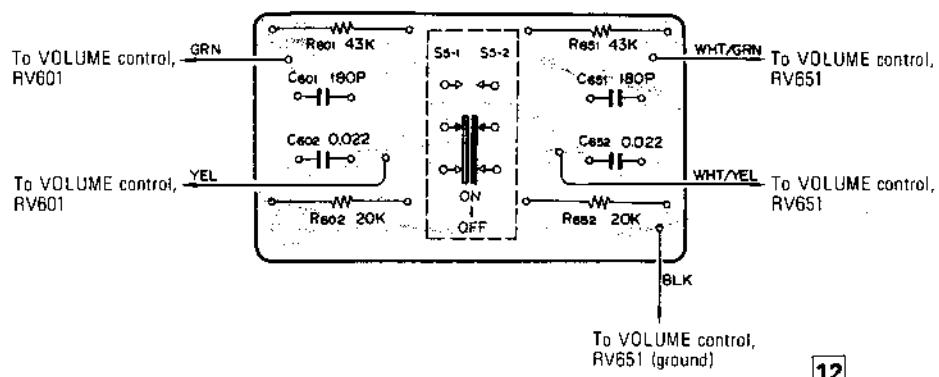

Fig. 4-1. Repacking

SECTION 5 DIAGRAMS
