CIRCUIT ALIGNMENT

Equipment Required.—An a.m. signal generator; a 0-1V a.c. voltmeter; an r.f. coupling coil and a 0.1μF capacitor.

1.—Connect the a.c. voltmeter across the loudspeaker and connect the signal generator via the 0.1μF capacitor to the junction C22, C23 and L1. Connect the earthing leads to battery positive in preference to the common "chassis" line, to avoid the possibility of short-circuiting the supply voltage.

(During alignment the output voltage across the loudspeaker should not be allowed to exceed 0.5V.)

2.—Turn the tuning knob fully anti-clockwise, turn the volume control to maximum. Feed in a 471kc/s signal and adjust the cores of L7, L9 and L11 for maximum output, repeating several times.

3.—Remove the signal generator and capacitor from L1 and connect the generator across the r.f. coupling coil. Place the coil about 3in away from the ferrite rod.

4.—Tune receiver to 500m. Feed in a 600kc/s signal and adjust L6 and L1 for maximum output.

5.—Tune receiver to 200m. Feed in a 1,500kc/s signal and adjust C25 and C23 for maximum output.

6.—Repeat operations 4 and 5.

7.—Tune receiver to 1,500m and check for reception of l.w. B.B.C. Light Programme.

Local Oscillator Check.—In the event of "no signal" fault conditions the operation of the oscillator may be checked by connecting a d.c. voltmeter across R3. If the oscillator is functioning a slight drop in the meter reading should be observed when the tuning gang oscillator section (C24) is short-circuited.

Battery.—9v Ever Ready PP3 or equivalent.
