Waveband switch diagrams, as seen in the direction of the arrows in our under-chassis view.

**CIRCUIT ALIGNMENT**

**IF Stages.**—Connect a signal generator to the grid (top cap) of **V1** via a  $0.01 \mu\text{F}$  condenser, and chassis. Leave the normal grid lead connected.

Turn receiver volume control to maximum. Feed in a 460 kc/s signal, and adjust the screws associated with the inductors **L15**, **L16**, **L17** and **L18** in that order for maximum output, keeping the input low to avoid AVC action. Repeat the adjustments until no further improvement results.

**RF and Oscillator Stages.**—With the gang at maximum, the pointer should cover the 1,950 m mark on the scale. Connect signal generator via a suitable dummy aerial to **A1** and **E** sockets.

**MW.**—Switch set to MW, tune to 200 m on scale, feed in a 200 m (1,500 kc/s) signal, fully unscrew **C41**, and then screw it up slowly until a peak is reached, finally adjusting it for maximum output. Tune to 550 m on scale, feed in a 550 m (645 kc/s) signal, and adjust **C31** and **C35** for maximum output, rocking the gang for optimum results; then adjust **C38** for maximum output, still rocking the gang. Return to 200 m, and check the setting of **C31** and **C35**.

**LW.**—Switch set to LW, tune to 1,000 m on scale, feed in a 1,000 m (300 kc/s) signal, and adjust **C42** for maximum output. Tune to 1,700 m on scale, feed in a 1,700 m (176.3 kc/s) signal, and adjust **C29** and **C32** for maximum output, rocking the gang for optimum results; then adjust **C39** for maximum output, still rocking the gang. Return to 1,000 m, and check the setting of **C29** and **C32**.

**EKCO - AW 87**

**Intermediate frequency 460 KC/S.**

\* Oscillator anode 120 V, 5.8 mA.

† Each anode, A.C.

**Chassis Divergence.**—In our chassis, **C1** and **C10** had the values shown in our tables: 0.00002 (20  $\mu\mu\text{F}$ ) and 0.00001 (10  $\mu\mu\text{F}$ ). In the makers' information these two values are transposed.
